Acquired Characters.—Every character is the result of two sets of factors, those resident in the germinal material and those imposed from without. Our knowledge has taken us far beyond any such idea as the formation of a germinal material by the collection of particles from the adult organs and tissues (gemmules of Darwin). The inheritance of any character means the transmission in the germinal material of matter which, brought under the necessary external conditions, develops into the character of the parent. There is necessarily an acquired or epigenetic side to every character; but there is nothing in our knowledge of the actual processes to make necessary or even probable the supposition that the result of that factor in one generation appears in the germ-plasm of the subsequent generations, in those cases where an embryological development separates parent and offspring. The development of any normal, so-called "innate," character, such as, say, the assumption of the normal human shape and relations of the frontal bone, requires the co-operation of many factors external to the developing embryo, and the absence of abnormal distorting factors. When we say that such an innate character is transmitted, we mean only that the germ-plasm has such a constitution that, in the presence of the epigenetic factors and the absence of abnormal epigenetic factors, the bone will appear in due course and in due form. If an abnormal epigenetic factor be applied during development, whether to the embryo *in utero*, to the developing child, or in after life, abnormality of some kind will appear in the bone, and such an abnormality is a good type of what is spoken of as an "acquired" character. Naturally such a character varies with the external stimulus and the nature of the material to which the stimulus is applied, and probability and observation lead us to suppose that as the germ-plasm of the offspring is similar to that of the parent, being a mass separated from the parent, abnormal epigenetic influences would produce results on the offspring similar to those which they produced on the parent. Scrutiny of very many cases of the supposed inheritance of acquired characters shows that they may be explained in this fashion—that is to say, that they do not necessarily involve any feature different in kind from what we understand to occur in normal development. The effects of increased use or of disuse on organs or tissues, the reactions of living tissues to various external influences, to bacteria, to bacterial or other toxins, or to different conditions of respiration, nutrition, and so forth, we know empirically to be different in the case of different individuals, and we may expect that when the living matter of a parent responds in a certain way to a certain external stimulus, the living matter of the descendant will respond to similar circumstances in a similar fashion. The operation of similar influences on similar material accounts for a large proportion of the facts. In the important case of the transmission of disease from parent to offspring it is plain that three sets of normal factors may operate, and other cases of transmission must be subjected to similar scrutiny: (1) a child may inherit the anatomical and physiological constitution of either parent, and with that a special liability of failure to resist the attacks of a widespread disease; (2) the actual bacteria may be contained in the ovum or possibly in the spermatozoon; (3) the toxins of the disease may have affected the ovum, or the spermatozoon, or through the placenta the growing embryo. Obviously in the first two cases the offspring cannot be said in any strict sense to have inherited the disease; in the last case, the theoretical nomenclature is more doubtful, but it is at least plain that no inexplicable factor is involved.

It is to be noticed, however, that "Lamarckians" and "Neo-Lamarckians" in their advocacy of an inheritance of "acquired characters" make a theoretical assumption of a different kind, which applies equally to "acquired" and to "innate" characters. They suppose that the result of the epigenetic factors are reflected on the germ-plasm in such a mode that in development the products would display the same or a similar character without the co-operation of the epigenetic factors on the new individual, or would display the result in an accentuated form if with the renewed co-operation of the external factors. Such an assumption presents its greatest theoretical difficulty if, with Weismann, we suppose the germ-plasm to be different in kind from the general soma-plasm, and its least theoretical difficulty if, with Hertwig, we suppose the essential matter of the reproductive cells to be similar in kind to the essential substance of the general body cells. But, apart from the differences between such theories, it supposes, in all cases where an embryological development lies between parent and descendant, the existence of a factor towards which our present knowledge of the actual processes gives us no assistance. The separated hereditary mass does not contain the organs of the adult; the Lamarckian factor would involve the translation of the characters of the adult back into the characters of the germ-cell in such a fashion that when the germ-cell developed these characters would be re-translated again into those which originally had been produced by co-operation between germ-plasm characters and epigenetic factors. In the present state of our

knowledge the theoretical difficulty is not fatal to the Lamarckian supposition; it does no more than demand a much more careful scrutiny of the supposed cases. Such a scrutiny has been going on since Weismann first raised the difficulty, and the present result is that no known case has appeared which cannot be explained without the Lamarckian factor, and the vast majority of cases have been resolved without any difficulty into the ordinary events of which we have full experience. Taking the empirical data in detail, it would appear first that the effects of single mutilations are not inherited. The effects of long-continued mutilations are not inherited, but Darwin cites as a possible case the Mahommedans of Celebes, in whom the prepuce is very small. Brown-Séquard thought that he had shown in the case of guinea-pigs the inheritance of the results of nervous lesions, but analyses of his results leave the question extremely doubtful. The inheritance of the effects of use and disuse is not proved. The inheritance of the effects of changed conditions of life is quite uncertain. Naegeli grew Alpine plants at Munich, but found that the change was produced at once and was not increased in a period of thirteen years. De Candolle starved plants, with the result of producing better blooms, and found that seedlings from these were also above the average in luxuriance of blossom, but in these experiments the effects of selection during the starvation, and of direct effect on the nutrition of the seeds, were not eliminated. Such results are typical of the vast number of experiments and observations recorded. The empirical issue is doubtful, with a considerable balance against the supposed inheritance of acquired characters.

Empirical Study of Effects of Amphimixis.—Inheritance is theoretically possible from each parent and from the ancestry of each. In considering the total effect it is becoming customary to distinguish between "blended" inheritance, where the offspring appears in respect of any character to be intermediate between the conditions in the parents; "prepotent" inheritance, where one parent is supposed to be more effective than the other in stamping the offspring (thus, for instance, Negroes, Jews, and Chinese are stated to be prepotent in crosses); "exclusive" inheritance, where the character of the offspring is definitely that of one of the parents. Such a classification depends on the interpretation of the word character, and rests on no certain grounds. An apparently blended character or a prepotent character may on analysis turn out to be due to the inheritance of a certain proportion of minuter characters derived exclusively from either parent. De Vries, arguing from experiments on plant hybrids, declares that no real mingling exists, but that the hybrids possess, in a simple form, some of the characters of each. He believes that characters must be analysed into ultimate units, and that when this is done the hybrid will be found never to exhibit the character of one parent (absent in the other) in a reduced form, but simply to have it or not to have it, and he obtained extremely interesting experimental results in support of his view. (For further details as to inheritance in crosses see HYBRIDISM.) Even leaving out of the question the actual interpretation of "character," there is a still greater difficulty, a fundamental one, in making empirical comparisons between the characters of parents and offspring. At first sight it seems as if this mode of work were sufficiently direct and simple, and involved no more than a mere collection of sufficient data. The cranial index, or the height of a human being and of so many of his ancestors being given, it would seem easy to draw an inference as to whether or no in these cases brachycephaly or stature were inherited. But our modern conceptions of the individual and the race make it plain that the problems are not so simple. With regard to any character, the race type is not a particular measurement, but a curve of variations derived from statistics, and any individual with regard to the particular character may be referable to any point of the curve. A tall race like the modern Scots may contain individuals of any height within the human limits; a dolichocephalic race like the modern Spaniards may contain extremely round-headed individuals. What is meant by saying that the one race is tall or the other dolichocephalic, is merely that if a sufficiently large number be chosen at random, the average height of the one race will be great, the cranial index of the other low. It follows that the study of variation must be associated with, or rather must precede, the empirical study of heredity, and we are beginning to know enough now to be certain that in both cases the results to be obtained are practically useless for the individual case, and of value only when large masses of statistics are collected. No doubt, when general conclusions have been established, they must be acted on for individual cases, but the results can be predicted not for the individual case, but only for the average of a mass of individual cases. It is impossible within the limits of this article to discuss the mathematical conceptions involved in the formation and applications of the method, but it is necessary to insist on the fact that these form an indispensable part of any valuable study of empirical data. One interesting conclusion, which may be called the "ancestral law" of heredity, with regard to any character, such as height, which appears to be a blend of the male and female characters, whether or no the apparent blend is really due to an exclusive inheritance of separate components, may be given from the work of Galton and Pearson. Each parent, on the average, contributes $\frac{1}{4}$ or $(0{\cdot}5)^2$, each grandparent $\frac{1}{16}$ or $(0{\cdot}5)^4$, and each ancestor of n^{th} place $(0{\cdot}5)^{2n}$. But, this, like all other deductions, is applicable only to the mass of cases and not to any individual case.

Regression.—An important result of the quantitative work brings into prominence the steady tendency to maintain the type which appears to be one of the most important results of amphimixis. In the tenth generation a man has 1024 tenth grandparents, and is thus the product of an enormous population, the mean of which can hardly differ from that of the general population. Hence this heavy weight of mediocrity produces regression or progression to type. Thus in the case of height, a large number of cases being examined, it was found that fathers of a stature of 72 inches had sons with a mean stature of 70·8 inches, a regression towards the normal stature of the race. Fathers with a stature of 66 inches had sons with a mean of 68·3 inches, a progression towards the normal. It follows from this that where there is much in-and-in breeding the weight of mediocrity will be less, and the peculiarities of the breed will be accentuated.

Atavism.—Under this name a large number of ordinary cases of variation are included. A tall man with very short parents would probably be set down as a case of atavism if the existence of a very tall ancestor were known. He would, however, simply be a case of normal variation, the probability of which may be calculated from a table of stature variations in his race. Less marked cases set down to atavism may be instances merely of normal regression. Many cases of more abnormal structure, which are really due to abnormal embryonic or post-embryonic development, are set down to atavism, as, for instance, the cervical fistulæ, which have been regarded as atavistic persistences of the gill clefts. It is also used to imply the reversion that takes place when domestic varieties are set free and when species or

varieties are crossed (see HYBRIDISM). Atavism is, in fact, a misleading name covering a number of very different phenomena.

Telegony is the name given to the supposed fact that offspring of a mother to one sire may inherit characters from a sire with which the mother had previously bred. Although breeders of stock have a strong belief in the existence of this, there are no certain facts to support it, the supposed cases being more readily explained as individual variations of the kind generally referred to as "atavism." None the less, two theoretical explanations have been suggested: (1) that spermatozoa, or portions of spermatozoa, from the first sire may occasionally survive within the mother for an abnormally long period; (2) that the body, or the reproductive cells of the mother, may be influenced by the growth of the embryo within her, so that she acquires something of the character of the sire. The first supposition has no direct evidence to support it, and is made highly improbable from the fact that a second impregnation is always necessary. Against the second supposition Pearson brings the cogent empirical evidence that the younger children of the same sire show no increased tendency to resemble him. (See TELEGONY.)

WEISMANN. *The Germ Plasm.* English translation by Parker. 1893.—Lists of separate papers are given in the annual volumes of the *Zoological Record* under heading "General Subject."

(P. C. M.)

Hereford, a municipal and parliamentary borough, railway station, ancient city, and county town of Herefordshire, England, on the river Wye, 144 miles from London by rail. Since 1885 its parliamentary representation has been reduced to one member. A musical festival of the choirs of Hereford, Gloucester, and Worcester cathedrals is held annually in rotation at these cities. The new gardens and public walk were opened in 1893. A suspension bridge for foot passengers across the river Wye was opened in 1897 as a memorial of Queen Victoria's Diamond Jubilee. The corporation commenced the supply of electricity in 1899. Area of borough, 5037 acres. Population (1881), 19,821; (1900), 21,382.

Herefordshire, a west midland county of England, bounded on the W. by Brecknock and Radnor in Wales, on the N. by Shropshire, on the W. by Worcester, and on the S. by Gloucester and Monmouth.

Area and Population.—The area of the ancient and administrative county, as given in the census returns of 1891, is 537,363 acres, or 840 square miles, with a population in 1881 of 121,249. and in 1891 of 115,949, of whom 56,090 were males and 59,859 females, the number of persons per square mile being 138, and of acres to a person 4·63. In 1894 the boundary of the administrative county was altered by a transference from Worcester, and a transference to Monmouth; in 1895 the parts of the parish of Leintwardine in Salop were transferred to Hereford; and in 1897 the parishes of Acton, Beauchamp, and Mathon Rural were transferred from Worcester to Hereford, and part of the parish of Cradley and the parish of Stoke Bliss from Hereford to Worcester. The area of the registration county is 535,846 acres, with a population in 1891 of 113,346, of which 32,427 were urban and 80,919 rural. Within the registration area the decrease of population between 1881 and 1891 was 3·93 per cent. Between 1881 and 1891 the excess of births over deaths was 11,374, but the decrease in population was 4642. In 1901 the population of the ancient county was 114,401.

The following table gives the numbers of marriages, births, and deaths, with the number of illegitimate births, for 1880, 1890, and 1898:—

Year.	Marriages.	Births.	Deaths.	Illegitimate Births.	
				Males.	Females.
1880	673	3420	2084	136	116
1890	708	2998	1943	106	93
1898	691	2814	1895	117	102

The number of marriages in 1899 was 759, of births 2808, and of deaths 1881.

The following table gives the marriage-, birth-, and death-rates per 1000 of the resident population, with the percentage of illegitimate births, for a series of years:—

	1870–79.	1880.	1880–89.	1890.	1888–97.	1898.
Marriage-rate .	11·6	11·3	11·6	12·4	12·9	12·6
Birth-rate .	28·9	28·8	27·3	26·3	26·8	25·7
Death-rate .	18·6	17·5	17·3	17·1	17·6	17·3
Percentage of Illegitimacy .	7·3	7·4	7·7	6·6	7·2	7·8

The marriage-, birth-, and death-rates are all much below the average, but the percentage of illegitimate births is much above it, as is usually the case in rural counties. In 1891 the natives of Scotland in the county numbered 2610, the natives of Ireland 4409, and foreigners 1717.

Constitution and Government.—The ancient county is divided into two parliamentary divisions, and it also includes the parliamentary borough of Hereford, returning one member. There are two municipal boroughs: Hereford (21,382) and Leominster (5826). The urban districts are Bromyard (1663), Kington (1953), Ledbury (3259), and Ross (3302). The county is in the Oxford circuit, and assizes are held at Hereford. The boroughs of Hereford and Leominster have separate commissions of the peace, and the borough of Hereford has in addition a separate court of quarter-sessions. The ancient county, which is almost entirely in the diocese of Hereford, contains 200 entire ecclesiastical parishes or districts, and parts of 20 others.

Education.—The number of elementary schools on 31st August 1899 was 191, of which 30 were board and 161 voluntary schools, the latter including 150 National Church of England schools, 4 Roman Catholic, and 7 "British and other." The average attendance at board schools was 3203, and at voluntary schools 12,432. The total school board receipts for the year ended 29th September 1898 were £11,160. The income under the Agricultural Rates Act was over £1041.

Agriculture.—About four-fifths of the total area of the county is under cultivation, and about two-thirds of this is in permanent pasture. Nearly 27,000 acres are under orchards—chiefly of apples and pears—the county, notwithstanding its much smaller area, ranking in this respect next to Devon. Over 40,000 acres are under woods, much of which is oak, and about 600 acres are under small fruit. About three-eighths of the total acreage under corn crops, which has largely diminished, is still occupied by wheat, but since 1880 its acreage has diminished by more than one-third; barley has decreased in acreage almost in proportion to the increase of the acreage under oats, which now occupies second place. Turnips occupy about three-fourths of the acreage under green crops, and both mangolds and vetches are also largely grown. About 7000 acres are under hops. The following table gives the main divisions of the cultivated area at intervals from 1880:—

Year.	Total area under Cultivation.	Corn Crops.	Green Crops.	Clover.	Permanent Pasture.	Fallow.
1880	443,854	100,315	31,114	38,429	255,693	12,302
1885	446,621	89,377	33,106	43,126	267,364	6,936
1890	444,974	85,690	30,928	37,313	278,542	5,785
1895	445,306	73,665	27,569	42,371	288,565	4,795
1900	447,974	76,575	25,406	38,237	297,421	2,355

The following table gives the numbers of the principal live stock for the same years:—

Year.	Total Horses.	Total Cattle.	Cows or Heifers in Milk or in Calf.	Sheep.	Pigs.
1880	21,326	75,221	24,829	260,099	21,054
1885	23,114	90,713	32,293	315,068	27,275
1890	22,203	87,911	30,577	326,347	30,040
1895	24,144	88,632	29,413	318,593	33,626
1900	23,357	96,503	32,374	330,270	24,286

Industries and Trade.—There are no signs of any revival of manufacturing enterprise. According to the report for 1898 of the chief inspector of factories (1900), the total number of persons employed in factories and workshops in 1897 was 2428, as compared with 2192 in 1896; of these 1710 persons were employed in non-textile factories. Paper is manufactured. Limestone was raised in 1899 to the amount of 13,646 tons.

(T. F. H.)

Herford, a town of Prussia, province of Westphalia, on the Werra, 60 miles by rail west-south-west of Hanover and 9 miles north-east of Bielefeld. It is the seat of considerable linen, cotton, sugar, furniture, carpet, and other industries. It has an agricultural school. Population (1885), 15,902; (1900), 25,120.

Hergenroether, Joseph von (1824–1890), German cardinal, was born at Würzburg, in Bavaria, 15th September 1824. He studied at Würzburg and at Rome. He afterwards became parish priest at Zellingen near his native city, in 1851 teacher, and in 1855 professor of Common Law in the University of Munich. Here he gained the reputation of being one of the most learned theologians on the Ultramontane side of the Infallibility question, which had begun to be discussed. In 1868 he was sent to Rome to arrange the proceedings of the Vatican Council. In 1870 he wrote *Anti-Janus*, an answer to the celebrated *Letters of Janus*, which made a great sensation at the time of the council. In 1877 he was made prelate of the Papal household; he became cardinal deacon in 1879, and was afterwards made curator of the Vatican archives. He wrote a standard and highly important life of Photius, Patriarch of Constantinople (1866–69), and he was also the author of a work on the Roman Catholic Church and the State in their historic development (Fribourg, 1872), a manual of Church history (1876), a sketch of the history of the Popes (Würzburg, 1879), and a life of Cardinal Maury (1878). He died in 1890. (J. J. L*.)

Heringsdorf, a seaside resort of Prussia, province of Pomerania, on the north coast of the island of Usedom, and 5 miles by rail north-west of Swinemünde. It is surrounded by beech woods, and is perhaps the most popular seaside resort on the German shore of the Baltic, being frequented by some 12,000 visitors annually.

Heri Rud. See HERAT.

Herisau, the largest town in the Swiss half-canton of Appenzell-Ausser-Rhoden, on the railway between Winkeln ($2\frac{1}{2}$ miles distant) and Appenzell ($13\frac{3}{4}$ miles distant). Its population (mainly Protestant and German-speaking) in 1901 was 13,518. It stands 2546 feet above the sea-level. Its church was built in 1516–20. The chief manufacture is that of muslins, and the town is by far the largest and most important in the entire canton.

Herkimer, capital of Herkimer county, New York, U.S.A., on the river Mohawk, on the Erie canal, and on the New York Central and Hudson River Railway. It is in a farming and dairy region. Population (1900), 5555, of whom 724 were foreign-born.

Herne, a town of Prussia, province of Westphalia, 15 miles by rail north-west of Dortmund. It has coal mines, boilerworks, gunpowder mills, &c. It was made a town in 1897. Population (1885), 9906; (1900), 27,999.

Herne Bay, a seaside resort of England, on the north coast of Kent, 62 miles by rail east from London, visited in summer by large numbers of London families. It has grown up since 1830, and has a somewhat pebbly beach, a pier nearly a mile long, and an esplanade. It has communication with London by steamboat, and in the season coaches run to Canterbury ($7\frac{1}{2}$ miles inland). Three miles to the east is Reculvers, the Roman *Regulbium*, a fortified camp for the protection of the Isle of Thanet. Its twin church towers are conspicuous objects, though the church was taken down, owing to the encroachments of the sea, in 1804. Bishop Ridley was at one time (16th century) vicar of Herne, the village behind Herne Bay. Population (1901), 6688.

Hernösand, a seaport town, on the east coast of Sweden, 3 miles south of the Ångerman river, connected by a branch line (70 miles) at Långsele with the main railway to the north of Sweden. It has an export trade in timber ($33\frac{1}{2}$ million cubic feet annually), iron, and wood-pulp. In 1900 the port was cleared by 783 vessels of 410,700 tons, but is, as a rule, closed by ice from the beginning of December to the beginning of May. Population (1890), 5789; (1900), 7890.

Herodas, or HERONDAS (for the name is spelt differently in the few places where he is mentioned), is the author of short humorous dramatic scenes in verse, written under the Alexandrian empire in the 3rd century B.C. Apart from the intrinsic merit of these pieces, they are interesting in the history of Greek literature as being a new species, illustrating Alexandrian methods. They are called Μιμίαμβοι, "Mime-iambics." Mimes were the Dorian product of South Italy and Sicily, and the most famous of them—from which Plato is said to have studied the drawing of character—were the work of Sophron. These were scenes in popular life, written in the language of the people, vigorous with racy proverbs such as we get in other reflections of that region—in Petronius and the *Pentamerone*. Two of the best known and the most vital among the "Idylls of Theocritus," the 2nd and the 15th, we know to have been derived from mimes of Sophron. What Theocritus is doing there, Herodas, his contemporary, is doing in another manner—casting old material into novel form, upon a small scale, under strict conditions of technique. The method is entirely Alexandrian: Sophron had written in a peculiar kind of rhythmical prose; Theocritus uses the hexameter and Doric, Herodas the "scazon" or "lame" iambic (with a dragging spondee at the end) and the old Ionic dialect with which that curious metre was associated. That, however, hardly goes beyond the choice and form of words; the structure of the sentences is close-knit Attic. But the grumbling metre and quaint language suit the tone of common life Herodas aims at realizing; for, as Theocritus may be called Idealist, Herodas is a Realist unflinching. His persons talk in vehement exclamations and emphatic turns of speech, with proverbs and fixed phrases; and occasionally, where it is designed as proper to the part, with the most naked coarseness of expression.

The scene of the second and the fourth (and presumably of all) is laid at Cos, and the speaking characters in each are never more than three. In Mime I. the old nurse, now the professional *go-between* or *bawd*, calls on Metriche, whose husband has been long away in Egypt, and endeavours to excite her interest in a most desirable young man, fallen deeply in love with her at first sight. After hearing all the arguments Metriche declines with dignity, but consoles the old woman with an ample glass of wine, this kind being always represented with the taste of Mrs Gamp. II. is a monologue by the Πορνοβοσκός (*whoremonger*) prosecuting a merchant-trader for breaking into his establishment at night and attempting to carry off one of the inmates, who is produced in court. The

vulgar blackguard, who is a stranger to any sort of shame, remarking that he has no evidence to call, proceeds to a peroration in the regular oratorical style, appealing to the Coan judges not to be unworthy of their traditionary glories. In fact, the whole oration is also a burlesque in every detail of an Attic speech at law; and in this case we have the material from which to estimate the excellence of the parody. In III. a desperate mother brings to the schoolmaster a truant urchin, with whom neither she nor his incapable old father can do anything. In a voluble stream of interminable sentences she narrates his misdeeds and implores the schoolmaster to flog him. The boy accordingly is hoisted on another's back and flogged; but his spirit does not appear to be subdued, and the mother resorts to the old man after all. IV. is a visit of two poor women with an offering to the temple of Asclepius at Cos. While the humble cock is being sacrificed, they turn, like the women in the *Ion* of Euripides, to admire the works of art; among them a small boy strangling a vulpanser—doubtless the work of Boethus that we know—and a sacrificial procession by Apelles, "the Ephesian," of whom we have an interesting piece of contemporary eulogy. The oily sacristan is admirably painted in a few slight strokes. V. brings us very close to some unpleasant facts of ancient life. The *jealous woman* accuses one of her slaves, whom she has made her favourite, of infidelity; has him bound and sent degraded through the town to receive 2000 lashes; no sooner is he out of sight than she recalls him to be branded "at one job." The only pleasing person in the piece is the little maidservant—permitted liberties as a *verna* brought up in the house—whose ready tact suggests to her mistress an excuse for postponing execution of a threat made in ungovernable fury. VI. is *a friendly chat* or *a private conversation*, the nature of which must be found out from the original. It is an ugly subject; but allowance being made for it, this dialogue between two women is as clever and amusing as the rest, with some delicious touches. Our interest is engaged here in a certain Kerdon, the artistic shoemaker, to whom we are introduced in VII. (the name had already become generic for the shoemaker as the typical representative of retail trade), a little bald man with a fluent tongue, complaining of hard times, who bluffs and wheedles by turns. VIII. opens with a mistress waking up her maids to listen to her dream; but we have only the beginning, and all the other fragments are too small to speak of here.

Within the limits of 100 lines or less Herodas presents us with a highly entertaining scene and with characters definitely drawn. Some of these had been perfected no doubt upon the Attic stage, where the tendency in the 4th century had been gradually to evolve accepted types—not individuals, but generalizations from a class, an art in which Menander's was esteemed the master-hand. The Πορνοβοσκός and the Μαστροπός we can piece together from succeeding literature, and see how skilfully the established traits are indicated here. This is achieved by true dramatic means, with touches never wasted and the more delightful often because they do not clamour for attention. The execution has the qualities of first-rate Alexandrian work in miniature, such as the epigrams of Asclepiades possess, the finish and firm outlines; and these little pictures bear the test of all artistic work—they do not lose their freshness with familiarity, and gain in interest as one learns to appreciate their subtle points.

The papyrus MS., obtained from the Fayyum, is in the possession of the British Museum, and was first printed by Mr Kenyon in 1891. The best text now is by Professor Crusius (Teubner), and there are convenient French versions (with introductions) by MM. Dalmeyda (Hachette), Ristelhueber (Delagrave), and Boisacq (Thorin). There is a complete edition, with commentary and translation by the writer of this article.

(W. G. H.)

Herschell, Farrer Herschell, 1st Baron (1837–1899), Lord High Chancellor of England, was born 2nd November 1837. His father was the Rev. Ridley Haim Herschell, a native of Strzelno, in Prussian Poland, who, when a young man, exchanged the Jewish faith for Christianity, took a leading part in founding the British Society for the Propagation of the Gospel among the Jews, and, after many journeyings, settled down to the incumbency of a Nonconformist chapel near the Edgware Road, in London, where he ministered to a large congregation. His mother was a daughter of Mr William Mowbray, a merchant of Leith. Foreign travel, a love for which he derived from his father, and music, which he learnt from his mother, were throughout Herschell's life his chief, if not his only, recreations. In 1854 young Herschell went to a grammar school at Denmark Hill, and shortly afterwards became a student at University College, Gower Street. In 1857 he took his B.A. degree at the University of London. He was reckoned the best speaker in the school debating society, and he displayed there the same command of language and lucidity of thought which were his characteristics during his official life. His early interest in oratory was so keen that when the debate on the seizure of the lorcha *Arrow* was announced to come on in the House of Commons, he spent six or seven hours in the dismal little room appropriated in those days to strangers, in order to secure a front seat in the gallery. The reputation which Herschell enjoyed during his school days was maintained after he became a law-student at Lincoln's Inn. In 1858 he entered the chambers of Mr Thomas Chitty, the famous common-law pleader, father of the late Lord Justice Chitty. His fellow pupils, amongst whom were A. L. Smith, afterwards Master of the Rolls, and Arthur Charles, afterwards judge of the Queen's Bench Division, gave him the sobriquet of "the chief baron" in recognition of his superiority. He subsequently read with Mr Hannen, afterwards Lord Hannen. In 1860 he was called to the bar and joined the northern circuit, then in its palmy days of undividedness. For four or five years he did not obtain much work. Fortunately, he was never a poor man, and so was not forced into journalism, or other paths of literature, in order to earn a living. Two of his contemporaries, each of whom achieved great eminence, found themselves in like case. One of these, Charles Russell, became Lord Chief-Justice of England; the other, William Court Gully, Speaker of the House of Commons. It is said that these three friends, dining together during a Liverpool assize some years after they had been called, agreed that their prospects were anything but cheerful. Certain it is that about this time Herschell meditated quitting England for Shanghai and practising in the consular courts there. Herschell, however, soon made himself useful to Edward James, the then leader of the northern circuit, and to John Richard Quain, the leading stuff-gownsman. For the latter he was content to note briefs and draft opinions, and when, in 1866, Quain donned "silk," it was on Herschell that a large portion of his mantle descended.

The first occasion on which Herschell greatly distinguished himself in court was as counsel for a young woman who was indicted at Carlisle for the murder of her illegitimate child, aged some two years, by drowning it in the Eden. The trial took place before Baron Bramwell, and at his request Herschell defended the accused. He did not succeed in obtaining an acquittal, the evidence against his client being too strong, but he made so

powerful a speech to the jury, that the learned baron commenced his summing up as follows:—"Gentlemen, there is one aspect of this trial which makes me proud of the profession to which I belong. The prisoner at the bar has apparently not a friend nor a shilling in the world, but no wealth or position could possibly have bought a more able, more eloquent, or more zealous defence than that which has been made on her behalf." This piece of "luck" (if that is the right word) became the opportunity which, being taken advantage of to the full, brought other opportunities in its train. Business began to flow in gradually, but not in any rushing stream. On the promotion of Quain to the bench in 1872, Herschell applied to be made a queen's counsel, an application which was granted as a matter of course. He had all the necessary qualifications for a leader—a clear, though not resonant voice; a calm, logical mind; a sound knowledge of legal principles; and (greatest gift of all) an abundance of common-sense. He never wearied the judges by arguing at undue length, and he knew how to retire with dignity from a hopeless cause. His only weak point was cross-examination. In handling a hostile witness he had neither the insidious persuasiveness of a Hawkins nor the compelling, dominating power of a Russell. But he made up for all by his speech to the jury, marshalling such facts as told in his client's favour with the most consummate skill. He very seldom made use of notes, but trusted to his memory, which he had carefully trained. By this means he was able to conceal his art, and to appear less as a paid advocate than as an outsider interested in the case anxious to assist the jury in arriving at the truth. By 1874 Herschell's business had become so good that he turned his thoughts to Parliament. Again his "luck" did not desert him. In February of that year there was a general election, with the result that the Conservative party came into power with a majority of fifty. The usual crop of petitions followed. The two Radicals (Thompson and Henderson) who had been returned for Durham City were unseated, and an attack was then made on the seats of two other Radicals (Bell and Palmer) who had been returned for Durham county. For one of these last Herschell was briefed. He made so excellent an impression on the local Radical leaders that they asked him to stand for Durham City; and after a fortnight's electioneering, he was elected as junior member. Between 1874 and 1880 Herschell was most assiduous in his attendance in the House of Commons. He was not a frequent speaker, but a few great efforts sufficed in his case to gain for him a reputation as a debater. The best examples of his style as a private member will be found in *Hansard* under the dates 18th February 1876, 23rd May 1878, 6th May 1879. On the last occasion he carried a resolution in favour of abolishing actions for breach of promise of marriage except when actual pecuniary loss had ensued, the damages in such cases to be measured by the amount of such loss. The grace of manner and solid reasoning with which he acquitted himself during these displays obtained for him the notice of Mr Gladstone, who in 1880 appointed Herschell Solicitor-General.

Herschell's public services from 1880 to 1885 were of great value, particularly in dealing with the "cases for opinion" submitted by the Foreign Office and other departments. He was also very helpful in speeding Government measures through the House, notably the Irish Land Act 1881, the Corrupt Practices and Bankruptcy Acts 1883, the County Franchise Act 1884, and the Redistribution of Seats Act 1885. This last was a bitter pill for Herschell, since it halved the representation of Durham City, and so gave him statutory notice to quit. Reckoning on the local support of the Cavendish family, he contested the North Lonsdale division of Lancashire; but in spite of the powerful influence of Lord Hartington, he was badly beaten at the poll, though Mr Gladstone again obtained a majority in the country. Herschell now thought he saw the Solicitor-Generalship slipping away from him, and along with it all prospect of high promotion. Lord Selborne and Sir Henry James, however, successively declined Mr Gladstone's offer of the Woolsack, and in 1886 Herschell, by a sudden turn of fortune's wheel, found himself in his forty-ninth year Lord Chancellor. This event had been neatly foreshadowed in a song written for some theatricals which took place at Christmas 1885 at Whitburn Hall, county Durham, the country house of the late Sir Hedworth Williamson, and sung in a burlesque by Sir Hedworth's eldest son, who was supposed to have met with a similar rebuff in a neighbouring constituency. The author of the song was Herschell's friend, Mr Hugh Shield, Q.C., "the poet of the northern circuit." One of its stanzas ran thus-

I then threw up the sponge—reflecting
  How oft electors judgment lack,
And felt less sore on recollecting
  That e'en Sir Farrer gets the sack.
Oh yes—he'll get the Sack again, too,
  In spite of North Lonsdale's defeat,
A worthier honour he'll attain to,
  And on the Woolsack find a seat.

Herschell's Chancellorship lasted barely six months, for in August 1886 Mr Gladstone's Home Rule Bill was rejected in the Commons and his Administration fell. In August 1892, when Mr Gladstone returned to power, Herschell again became Lord Chancellor. In September 1893, when the second Home Rule Bill came on for second reading in the House of Lords, Herschell took advantage of the opportunity to justify the "sudden conversion" to Home Rule of himself and his colleagues in 1885 by comparing it to the Duke of Wellington's conversion to Catholic Emancipation in 1829 and to that of Sir Robert Peel to Free Trade in 1846. In 1895, however, his second Chancellorship came to an end with the defeat of the Rosebery Ministry.

Whether sitting at the Royal Courts in the Strand, on the judicial committee of the Privy Council, or in the House of Lords, Lord Herschell's judgments were distinguished for their acute and subtle reasoning, for their grasp of legal principles, and, whenever the occasion arose, for their broad treatment of constitutional and social questions. He was not a profound lawyer in the sense in which that term was applied to Lord Blackburn or Mr Justice Willes, but his quickness of apprehension was such that it was an excellent substitute for great learning. In construing a real property will or any other document, his first impulse was to read it by the light of nature, and to decline to be influenced by the construction put by the judges on similar phrases occurring elsewhere. But when he discovered that certain expressions had acquired a technical meaning which could not be disturbed without fluttering the dovecotes of the conveyancers, he would yield to the established rule, even though he did not agree with it. He was perhaps seen at his judicial best in *Vagliano* v. *Bank of England* (1891) and *Allen* v. *Flood* (1898). Latterly he showed a tendency, which seems to grow on some judges, to interrupt counsel overmuch. The case last mentioned furnishes an example of this. The question involved was what constituted a molestation of a man in the pursuit of his lawful calling. At the close of the argument of counsel, whom he had frequently interrupted, one of their lordships, noted for his pretty wit, observed that although there might be a doubt as to what amounted to such molestation in point

of law, the House could well understand, after that day's proceedings, what it was in actual practice. In addition to his political and judicial work, Herschell rendered many public services. In 1888 he presided over an inquiry directed by the House of Commons with regard to the Metropolitan Board of Works. He acted as chairman of two royal commissions, one on Indian currency, the other on vaccination. He took a great interest in the National Society for the Prevention of Cruelty to Children, not only promoting the Acts of 1889 and 1894, but also bestowing a good deal of time in sifting the truth of certain allegations which had been brought against the management of that society. In June 1893 he was appointed chancellor of the University of London in succession to the Earl of Derby, and he entered on his new duties with his usual thoroughness. "His views of reform," writes Mr Victor Dickins, the accomplished registrar of the university, "were always most liberal and most frankly stated, though at first they were not altogether popular with an important section of university opinion. He disarmed opposition by his intellectual power, rather than conciliated it by compromise, and sometimes was perhaps a little masterful, after a fashion of his own, in his treatment of the various burning questions that agitated the university during his tenure of office. His characteristic power of detachment was well illustrated by his treatment of the proposal to remove the university to the site of the Imperial Institute at South Kensington. Although he was at that time chairman of the Institute, the most irreconcilable opponent of the removal never questioned his absolute impartiality." With the Imperial Institute Herschell had been officially connected from its inception. He was chairman of the provisional committee appointed by the Prince of Wales to formulate a scheme for its organization, and he took an active part in the preparation of its charter and constitution in conjunction with Lord Thring, Lord James, Sir Frederick Abel, and Mr John Hollams. He was the first chairman of its council, and, except during his tour in India in 1888, when he brought the Institute under the notice of the Indian authorities, he was hardly absent from a single meeting. For his special services in this connexion he was made G.C.B. in 1893, this being the only instance of a Lord Chancellor being decorated with an order.

In 1897 he was appointed, jointly with Lord Justice Collins, to represent Great Britain on the Venezuela Boundary Commission, which assembled in Paris in the spring of 1899. So complicated a business involved a great deal of preparation and a careful study of maps and historic documents. Not content with this, he accepted in 1898 a seat on the joint high commission appointed to adjust certain boundary and other important questions pending between Great Britain and Canada on the one hand and the United States on the other hand. He started for America in July of that year, and was received most cordially at Washington. His fellow commissioners elected him their president. In February 1899, while the commission was in full swing, he had the misfortune to slip in the street, and in falling to fracture a hip bone. He bore his confinement to bed with stoic fortitude, and no word of complaint escaped his lips. But his constitution, which at one time was a robust one, had been undermined by constant hard work, and proved unequal to sustaining the shock. On 1st March, only a fortnight after the accident, he died at the Shoreham Hotel, Washington, a *post-mortem* examination revealing disease of the heart. Mr Hay, Secretary of State, at once telegraphed to Mr Choate, the United States ambassador in London, the "deep sorrow" felt by President McKinley; and Sir Wilfred Laurier said the next day, in the Parliament Chamber at Ottawa, that he regarded Herschell's death "as a misfortune to Canada and to the British Empire." A funeral service held in St John's Episcopal Church, Washington, was attended by the President and Vice-President of the United States, by the cabinet ministers, the judges of the supreme court, the members of the joint high commission, and a large number of senators and other representative men. The body was brought to London in a British man-of-war, and a second funeral service was held in Westminster Abbey before it was conveyed to its final resting-place at Tincleton, Dorset, in the parish church of which he had been married. Herschell left a widow, granddaughter of Vice-Chancellor Kindersley; a son, Richard Farrer, who succeeded him as second baron; and two daughters.

AUTHORITIES.—In the above article use has been made mainly of private information and personal knowledge. A "reminiscence" of Herschell by Mr Speaker Gully will be found in *The Law Quarterly Review* for April 1899. *The Journal of the Society of Comparative Legislation* (of which he had been president from its formation in 1893) contains, in its part for July of the same year, notices of him by Lord James of Hereford, Lord Davey, Mr Victor Williamson (his executor and intimate friend), and also by Mr Justice Brewer and Senator Fairbanks (both of the United States). (M. H. C.)

Hersfeld, a town of Prussia, province of Hesse-Nassau, 26 miles north of Fulda by rail, and on the river Fulda. The parish church was restored in 1899. Here is a military school. Population (1885), 7262; (1900), 7908.

Herstal, a town of Belgium, in the province and 3 miles by rail N.E. of the town of Liége, of which it is almost a suburb. In 1889 a syndicate of Liége gunmakers, having received an order from the Government for 150,000 military repeating rifles, founded "La Fabrique Nationale d'Armes de Guerre" here. It is the second largest private factory of military repeating rifles in Europe. The motive power of the works is supplied by electricity. About 1000 workmen and 900 workwomen are employed. They are capable of turning out 250 completely finished repeating rifles and 25,000 cartridges a day. Population (1899), 17,655.

Hertford, a municipal borough (extended, 1892), market-town, and county town in the Hertford parliamentary division (since 1885) of the county of Hertfordshire, England, on the Lea, 23 miles north of London by rail. The old church of All Saints' was burned in 1891; a new one has been erected, in the Perpendicular style, of red Runcorn stone. Other recent erections include a public library and school of art, a Congregational hall, a Volunteer drill-hall and armoury, and a joint hospital (Hertford and Ware) for infectious diseases. The shire hall or town-hall and the general infirmary have been enlarged. Works for Oriental printing have been introduced. Population, on 816 acres (1881), 7714; (1891), 7548; (1891), on the area as afterwards extended (1136 acres), 9023; (1901), 9322.

Hertfordshire, a south midland county of England, bounded on the S. by Middlesex, on the S.W. by Buckingham, on the N.W. by Bedford, on the N. by Cambridge, and on the E. by Essex.

Area and Population.—The area of the ancient county is 406,161 acres, or 635 square miles, with a population in 1881 of 203,140, and in 1891 of 220,162, of whom 106,471 were males and 113,691 females; the number of persons per square mile being 347, and of acres to a person 1·84. The area of the administrative county, as given in the census returns, is 406,932 acres, with a population in 1891 of 224,532; but several alterations in the area have since taken place. In 1895 the parish of Nettleden and

parts of the parish of Ivinghoe were transferred from Buckingham; in 1896 additions were made by the transference from Cambridge of the parish of Royston, and the part of each of the parishes of Bassingbourne, Kneesworth, and Melbourn, which is included in the North Royston special drainage district, and by the transference from Middlesex of part of the rural district and parish of South Mimms; and in 1897 part of the parish of Caddington, and the parishes of Kensworth and Studham were transferred to Bedford, while the hamlet of Humbershoe, part of the parish of Houghton Regis, the parish of Holywell, and parts of the parish of Shillington were transferred from Bedford. The area of the registration county is 443,787 acres, with a population in 1891 of 215,179, of whom 68,118 were urban and 147,061 rural. Within the registration area the increase of population between 1881 and 1891 was 6·29 per cent., the increase being due chiefly to the erection of villas in the districts adjoining London. Between 1881 and 1891 the excess of births over deaths was 25,361, and the actual increase in the resident population was 1233. The population in 1901 was 250,350.

The following table gives the number of marriages, births, and deaths, with the number of illegitimate births, for 1880, 1890, and 1898:—

Year.	Marriages.	Births.	Deaths.	Illegitimate Births.	
				Males.	Females.
1880	1093	6254	3567	161	172
1890	1228	5722	3579	161	117
1898	1545	5680	3446	138	106

The number of marriages in 1899 was 1615, of births 5701, and of deaths 3673.

The following table gives the marriage-, birth-, and death-rates per 1000 of the population, with the percentage of illegitimate births, for a series of years:—

	1870–79.	1880.	1880–89.	1890.	1889–98.	1899.
Marriage-rate	11·8	10·8	10·7	11·5	11·9	13·8
Birth-rate	32·2	30·9	29·5	26·7	26·7	25·4
Death-rate	18·7	17·6	17·0	16·7	16·0	15·4
Percentage illegitimate births	5·9	5·3	4·4	4·2	4·8	4·3

In 1891 there were in the county 1344 Scots, 841 Irish, and 525 foreigners.

Constitution and Government.—The ancient county is divided into four parliamentary divisions, and has no parliamentary borough. The administrative county contains three municipal boroughs: Hemel Hempstead (11,264 in 1901), Hertford (9322), and St Albans (16,019). The following are urban districts: Baldock (2057), Barnet (7876), Bishop's Stortford (7143), Cheshunt (12,288), East Barnet Valley (10,094), Great Berkhampstead (5219), Harpenden (4725), Hitchin (10,072), Hoddesdon (4711), Rickmansworth (5627), Royston (3517), Stevenage (3957), Tring (4368), Ware (5573), and Watford (29,023). The county is in the home circuit, and assizes are held at Hertford. The boroughs of Hertford and St Albans have separate commissions of the peace. All the civil parishes within 12 miles of, or of which no portion is more than 15 miles from, Charing Cross, are included in the metropolitan police district. The ancient county, which is chiefly in the diocese of St Albans, contains 159 entire ecclesiastical parishes or districts and parts of 5 others.

Education.—There is a residential college for schoolmistresses (St Albans Diocesan) at Bishop's Stortford. The number of elementary schools on 31st August 1899 was 241, of which 39 were board and 202 voluntary schools; the latter including 183 National Church of England schools, 4 Roman Catholic, and 15 "British and other." The average attendance at board schools was 9405, and at voluntary schools 27,633. The total school board receipts for the year ended 29th September 1898 were over £46,224. The income under the Technical Instruction Act was over £171, and that under the Agricultural Rates Act was over £857.

Agriculture.—There is an increasing London trade in corn, malt, vegetables, and fruit. More than three-fourths of the total area is under cultivation, and more than one-third of this is in permanent pasture. Over 1700 acres are under orchards, chiefly of apples and cherries; and strawberries also are largely grown. Wheat still occupies nearly one-half of the total area under corn crops, but its acreage is gradually diminishing; oats and barley occupy each about one-fourth. About two-thirds of the area under green crops is occupied by turnips, swedes, and mangolds, many cows being kept for the supply of milk and butter to London. The following table gives the larger main acreages of the cultivated area at intervals of five years from 1880:—

Year.	Total Area under Cultivation.	Corn Crops.	Green Crops.	Clover.	Permanent Pasture.	Fallow.
1880	340,117	144,038	40,436	37,445	98,765	19,430
1885	341,381	137,062	43,787	39,793	106,812	13,924
1890	341,782	133,122	36,349	41,483	116,134	14,394
1895	336,147	120,130	34,415	45,804	118,126	16,957
1900	332,187	121,498	32,425	45,667	120,687	11,289

The following table gives particulars regarding the principal live stock for the same years:—

Year.	Total Horses.	Total Cattle.	Cows or Heifers in Milk or in Calf.	Sheep.	Pigs.
1880	14,846	33,032	12,125	155,011	27,975
1885	13,975	37,731	13,708	169,507	32,464
1890	14,425	33,009	13,036	146,848	33,103
1895	15,554	30,068	12,734	121,480	33,689
1900	15,023	35,732	14,681	112,413	24,424

Industries and Trade.—According to the annual report for 1898 of the inspector of factories (1900), the total number of persons employed in factories and workshops in 1897 was 11,770, as compared with 10,418 in 1896. Non-textile factories employed 8503 persons, of whom 2953 were employed in the manufacture of paper. Watford is famed for its ales. Of the 2990 persons employed in workshops, 2003 were employed in clothing industries. In 1899, 46,888 tons of chalk were raised, 105,142 tons of gravel and sand, and 59,760 tons of clay.

(T. F. H.)

Hertz, Heinrich Rudolf (1857–1894), German physicist, was born at Hamburg on 22nd February 1857. On leaving school he determined to adopt the profession of engineering, and in pursuance of this decision went to study in Munich in 1877. But soon coming to the conclusion that engineering was not his vocation he abandoned it in favour of physical science, and in October 1878 began to attend the lectures of Kirchhoff and Helmholtz at Berlin. In preparation for these he spent the winter of 1877–78 in reading up original treatises like those of Laplace and Lagrange on mathematics and mechanics, and in attending courses on practical physics under Jolly and Bezold; the consequence was that within a few days of his arrival in Berlin in October 1878 he was able to plunge into original research on a problem of electric inertia. For the best solution a prize was offered by the philosophical faculty of the University, and this he succeeded in winning with the paper which was published in 1880 on the "Kinetic Energy of Electricity in Motion." His next investigation, on "Induction in Rotating Spheres," he offered in 1880 as his dissertation for his doctor's degree, which he obtained with the rare distinction of *summâ cum laude.* Later in the same year he became assistant to Helmholtz in the physical laboratory of the Berlin Institute. During the three years he held this position he carried out researches on the contact of elastic solids, hardness, evaporation, and the electric discharge in gases, the last earning him the special commendation of Helmholtz. In 1883 he went to Kiel, becoming *privat-docent,* and there he began the studies in Maxwell's electromagnetic theory which a few years later resulted in the discoveries that rendered his name famous. These were actually made between 1885 and 1889, when he was

professor of physics in the Carlsruhe Polytechnic. He himself has recorded that their origin is to be sought in a prize problem proposed by the Berlin Academy of Science in 1879, having reference to the experimental establishment of some relation between electromagnetic forces and the dielectric polarization of insulators. Imagining that this would interest Hertz and be successfully attacked by him, Helmholtz specially drew his attention to it, and promised him the assistance of the Institute if he decided to work on the subject; but Hertz did not take it up seriously at that time, because he could not think of any procedure likely to prove effective. It was of course well known, as a necessity of Maxwell's mathematical theory, that the polarization and depolarization of an insulator must give rise to the same electromagnetic effects in the neighbourhood as a voltaic current in a conductor. The experimental proof, however, was still lacking, and though several experimenters had come very near its discovery, Hertz was the first who actually succeeded in supplying it, in 1887. Continuing his inquiries for the next year or two, he was able to discover the progressive propagation of electromagnetic action through space, to measure the length and velocity of electromagnetic waves, and to show that in the transverse nature of their vibration and their susceptibility to reflection, refraction, and polarization they are in complete correspondence with the waves of light and heat. The result was, in Helmholtz's words, to establish beyond doubt that ordinary light consists of electrical vibrations in an all-pervading ether which possesses the properties of an insulator and of a magnetic medium. Hertz himself gave an admirable account of the significance of his discoveries in a lecture on the relations between light and electricity, delivered before the German Society for the Advancement of Natural Science and Medicine at Heidelberg in September 1889. Since the time of these early experiments, various other modes of detecting the existence of electric waves have been found out in addition to the spark-gap which he first employed, and the results of his observations, the earliest interest of which was simply that they afforded a confirmation of an abstruse mathematical theory, have been applied to the practical purposes of signalling over considerable distances (see TELEGRAPHY, WIRELESS). In 1889 Hertz was appointed to succeed Clausius as ordinary professor of physics in the University of Bonn. There he continued his researches on the discharge of electricity in rarefied gases, only just missing the discovery of the X-rays described by Röntgen a few years later, and produced his treatise on the *Principles of Mechanics.* This was his last work, for after a long illness he died at Bonn on 1st January 1894. By his premature death science lost one of her most promising disciples. Helmholtz thought him the one of all his pupils who had penetrated farthest into his own circle of scientific thought, and looked to him with the greatest confidence for the further extension and development of his work.

Hertz's scientific papers have been translated into English by Professor D. E. Jones, and published in three volumes: *Electric Waves* (1893), *Miscellaneous Papers* (1896), and *Principles of Mechanics* (1899). The preface contributed to the first of these by Lord Kelvin, and the introductions to the second and third by Professors Lenard and Helmholtz, contain many biographical details, together with statements of the scope and significance of his investigations. A book by Dr Oliver Lodge on *Hertz and His Work* (London, 1895) may also be consulted. (H. M. R.)

Herzegovina. See BOSNIA AND HERZEGOVINA.

Hesse-Darmstadt, a grand-duchy of Germany, situated partly on the Rhine and Main, and partly surrounded by the province of Hesse-Nassau. Of the total area (2966 square miles), 64 per cent. is under cultivation, whilst forests cover over 31 per cent. The total number of farms in 1895 was 133,840, and of these 59,043 were less than $2\frac{1}{2}$ acres each, 65,419 between $2\frac{1}{2}$ and 25 acres (93 per cent. under 25 acres each), 9255 between 25 and 250 acres, and 123 exceeding 250 acres. In 1898 vines covered 30,840 acres, and produced 2,791,320 gallons of wine, valued at £225,000. The live stock in 1897 numbered 324,626 cattle, 271,595 pigs, 86,731 sheep, and 56,002 horses. In 1898 mineral products yielded 159,430 tons of iron ore, valued at £61,200; 218,384 tons of lignite, valued at £30,000; 37,916 tons of sulphuric acid, valued at £40,300; and 16,680 tons of salt, valued at £15,400. The smelting furnaces produced 19,868 tons of iron, valued at £188,500. In 1898–99 the sugar refineries yielded 14,000 tons of sugar; the breweries, 31,037,800 gallons of beer; and the distilleries, 398,100 gallons of pure alcohol. The grand-duchy is divided into three provinces, with area and population as follows:—

Provinces.	Area.	Pop. 1885.	Pop. 1890.	Pop. 1895.	Density per sq. Mile, 1895.
Upper Hesse .	1269	263,044	265,912	271,524	213·9
Rhenish Hesse .	531	291,142	307,329	322,934	608·1
Starkenburg .	1166	402,370	419,642	444,562	381·3
Totals . .	2966	956,556	992,883	1,039,020	350·3

In 1900 the population of the grand-duchy was 1,120,426, of whom 558,962 were males and 561,464 females. The number of emigrants who left the country decreased from 2503 in 1885 to 333 in 1899. In 1895 the Protestants numbered 694,962, or 67 per cent. of the whole; Roman Catholics 305,906, or 30 per cent.; and there were 24,618 Jews. For the year 1900–1 the ordinary revenue was estimated at £1,871,400, and the ordinary expenditure at £1,868,600; in addition there was an extraordinary revenue estimated at £602,600, and an extraordinary expenditure estimated at £483,700. In 1900 the public debt amounted to £13,373,200; and in 1900 the state contribution to the empire was fixed at £523,270.

Hesse-Nassau, a province of Prussia, with an area of 6060 square miles and a population of 1,897,981 (1900). The principal crops are potatoes and hay, oats, rye, and beetroot (for sugar), wheat, and barley. The vine was cultivated on 7490 acres in 1898, 97 per cent. of which were in the district of Wiesbaden; the yield of wine being 272,700 gallons, valued at £27,540, and including such brands as Johannisberg, Rüdesheim, Marcobrunner, Rauenthal, Assmannshausen, &c. But the year 1898 was a bad year for wine, the average yield for the years 1888–1897 having been 167 gallons annually per acre, as against $36\frac{1}{2}$ gallons in 1898. Tobacco and hops are also grown, though not on an extensive scale. Gardening, and the cultivation of fruit and vegetables, thrive in certain favoured localities. This province is an important pastoral region, and in 1897 possessed 565,303 cattle, 464,479 pigs, 390,790 sheep, and 80,544 horses. It has also one of the relatively largest forest areas (40 per cent. of province) in the kingdom of Prussia. Mining is one of the chief industries of the province. The production in 1898 amounted to 614,409 tons of iron, valued at £243,400; 380,275 tons of lignite, valued at £73,300; 9983 tons of lead, valued at £66,800; 12,197 tons of zinc, valued at £45,100; further, manganese, salt, and copper. The furnaces and smelting-works produced 24,637 tons of lead, valued at £312,900; 778,320 ounces of silver, valued at £113,400; 79,318 tons of iron, valued at £802,650; and 81,025 tons of sulphuric acid, valued at £98,900. In 1898–99 the sugar refineries yielded 10,370 tons of sugar;

the breweries, 45,666,800 gallons of beer; and the distilleries, 364,000 gallons of pure alcohol. There are numerous sandstone, slate, and clay quarries. The province is famous for its mineral springs, which abound specially in the Taunus region; the best known of the spas are Wiesbaden, Ems, Homburg, Schlangenbad, Schwalbach, Soden, &c. (For further particulars, see under PRUSSIA.)

Hewett, Sir Prescott Gardner, BART. (1812–1891), British surgeon, was born 3rd July 1812, being the son of a Yorkshire country gentleman. He lived for some years in early life in Paris, and started on a career as an artist, but abandoned it for surgery. He entered St George's Hospital, London (where his half-brother, Dr Cornwallis Hewett, was physician from 1825 to 1833), becoming demonstrator of anatomy and curator of the museum. He was the pupil and intimate friend of Brodie, and helped him in much of his work. Eventually he rose to be anatomical lecturer, assistant-surgeon, and surgeon to the hospital. In 1876 he was President of the College of Surgeons; in 1877 he was made serjeant-surgeon extraordinary to Queen Victoria, in 1884 serjeant-surgeon, and in 1882 he was created a baronet. He was a very good lecturer, but shrank from authorship; his lectures on *Surgical Affections of the Heart* were, however, embodied in his treatise on the subject in Holmes's *System of Surgery*. As a surgeon he was always extremely conservative, but hesitated at no operation, however severe, when convinced of its expediency. He was a perfect operator, and one of the most trustworthy of counsellors. He died 19th June 1891.

Hexham, a market-town and parish of England, county of Northumberland, on the south bank of the Tyne, 20 miles west of Newcastle, on the railway to Carlisle. In the neighbourhood there are barytes and coal mines. Since 1882 the town has belonged to the diocese of Newcastle. During the Middle Ages Hexham enjoyed peculiar rights of sanctuary, and the district around, known as Hexhamshire, formed a separate liberty down to the close of the 16th century. The Lancastrians were defeated by the Yorkists near here in 1463. Dr Joseph Parker, the well-known London preacher, was born at Hexham in 1830, and gives particulars of his early life there in his book, *A Preacher's Life*. Hexham gives its name to one of the four parliamentary divisions of the county. Area of urban sanitary district, 5136 acres. Population (1891), 5945; (1901), 7071.

Heyse, Johann Ludwig Paul (1830-——), German novelist and poet, was born at Berlin on 15th March 1830, being the son of the distinguished philologist. After producing in 1848 *Der Jungbrunnen*, a fanciful little tale entirely in the spirit of the romantic school, and in 1851 a tragedy on the story of Francesca da Rimini, he turned his attention to novel writing, and published at Munich in 1855 four novelettes in one volume, two of which at least were absolute masterpieces. These were the precursors of a series of similar volumes, necessarily unequal at times, but on the whole constituting such a mass of highly complex miniature fiction as perhaps never before proceeded from the pen of a single writer. Heyse works in the spirit of a sculptor: he seizes upon some picturesque incident or situation, and chisels and polishes until all the effect which it is capable of producing has been extracted from it. The success of the story usually depends upon the merit of the theme, for the artist's skill is generally much the same, and the situation usually leaves a deeper impression than the characters. Heyse is also the author of several novels on a larger scale, all of which have gained success and provoked abundant discussion. The more important are *Kinder der Welt* (1873), dealing with general, *Im Paradiese* (1875), with artistic society, and *Merlin* (1892), a defence of the idealism of life. He has also been a prolific but not a very successful dramatist, and has produced masterly translations of Leopardi, Giusti, and other southern poets.

Heywood, a municipal borough (1881), in the Heywood parliamentary division of Lancashire, England, 3 miles east of Bury and 9 miles north of Manchester, on the Lancashire and Yorkshire Railway. A technical school was opened in 1894. Heywood is a manufacturing town with an increasing population. Area, 3628 acres. Population (1881), 22,979; (1901), 25,461.

Hicks-Beach, Sir Michael Edward, BART. (1837-——), English statesman, son of the 8th baronet, whom he succeeded in 1854, was born in London in 1837, and educated at Eton and Christ Church, Oxford, where he graduated with a first-class in the school of law and modern history. In 1864 he was returned to Parliament as a Conservative for East Gloucestershire, the county in which his estates of Williamstrip Park were situated; and during 1868 he acted both as Parliamentary Secretary to the Poor Law Board and as Under-Secretary for the Home Department. In 1874 he married the daughter of the 3rd Earl Fortescue. In the same year he was made Chief Secretary for Ireland, and was included in the Cabinet in 1877. From 1878 to 1880 he was Secretary of State for the Colonies. In 1885 he was elected for West Bristol, and the Conservative party having returned to power, became Chancellor of the Exchequer and leader of the House of Commons. After Mr Gladstone's brief Home Rule Ministry in 1886 he entered Lord Salisbury's next Cabinet again as Irish Secretary, making way for Lord Randolph Churchill as leader of the House; but troubles with his eyesight compelled him to resign in 1887, and meanwhile Mr Goschen replaced Lord Randolph as Chancellor of the Exchequer. From 1888 to 1892 Sir Michael Hicks-Beach returned to active work as President of the Board of Trade, and in 1895—Mr Goschen being transferred to the Admiralty—he again became Chancellor of the Exchequer. As a Finance Minister he showed himself not only a vigorous guardian of the public purse, but also a particularly lucid expositor of his Budgets. In 1899 he lowered the fixed charge for the National Debt from twenty-five to twenty-three millions—a reduction imperatively required, apart from other reasons, by the difficulties found in redeeming Consols at their then inflated price. When compelled to find means for financing the war in South Africa, he insisted on combining the raising of loans with the imposition of fresh taxation; and besides raising the income-tax each year, up to 1s. 3d. in 1902, he introduced taxes on sugar and exported coal (1901), and in 1902 proposed the reimposition of the registration duty on corn and flour which had been abolished in 1869 by Mr Lowe. The sale of his Netheravon estates in Wiltshire to the War Office in 1898 occasioned some acrid criticism concerning the valuation, for which, however, Sir Michael himself was not responsible.

Hidalgo, a state of Mexico, bounded on the N. by the states of San Luis Potosí and Veracruz, on the E. by Puebla, on the S. by Mexico and Tlaxcala, and on the W. by Queretaro. Area, 8920 square miles. Population (1879), 427,350; (1900), 603,074. The agricultural products comprise cereals, coffee, sugar, cotton, tobacco, and maguey. Mining is the most important industry, the chief products being gold, silver, mercury, copper, iron, lead, zinc, antimony, manganese, and plumbago. The

state is divided into fifteen districts. The capital is Pachuca (40,487), and among other towns are Tulancingo (8303), Ixmiquilpan (7079), Actopan (5635).

Hiel, Emmanuel (1834–1899), Belgian-Dutch poet and prose writer, was born at Dendermonde, in Flanders, May 1834. He acted in various functions, from teacher and government official to journalist and bookseller, busily writing all the time both for the theatre and the magazines of North and South Netherlands. His last posts were those of librarian at the Industrial Museum and professor of declamation at the Conservatoire in Brussels. Among his better-known poetic works may be cited *Looverkens* ("Leaflets," 1857); *Nieuwe Liedekens* ("New Poesies," 1861); *Gedichten* ("Poems," 1863); *Psalmen, Zangen, en Oratorios* ("Psalms, Songs, and Oratorios," 1869); *De Wind* (1869), an inspiriting cantata, which had a large measure of success and was crowned; *De Liefde in 't Leven* ("Love in Life," 1870); *Elle* and *Isa* (two musical dramas, 1874); *Liederen voor Groote en Kleine Kinderen* ("Songs for Big and Small Folk," 1879); *Jakoba van Beieren* ("Jacquelein of Bavaria," a poetic drama, 1880); *Mathilda van Denemarken* (a lyrical drama, Ghent, 1890). His collected poetical works were published in three volumes at Rousselaere in 1885. Hiel took an active and prominent part in the so-called "Flemish movement" in Belgium, and we therefore find his name constantly associated with those of Jan van Beers, the Willems, and Peter Benoit. The last wrote some of his compositions to Hiel's verses, notably to his oratorios *Lucifer* (performed in London at the Royal Albert Hall and elsewhere) and *De Schelde* ("The Scheldt"); whilst the Dutch composer, Richard Hol (of Utrecht), composed the music to Hiel's "Ode to Liberty," and Van Gheluwe to the poet's "Songs for Big and Small Folk" (second edition, much enlarged, 1879), which has greatly contributed to their popularity in schools and among Belgian choral societies. Hiel also translated several foreign lyrics. His rendering of Tennyson's *Dora* appeared at Antwerp in 1871. For the national festival of 1880 at Brussels, to commemorate the fiftieth anniversary of Belgian independence, Hiel composed two cantatas, *Belgenland* ("The Land of the Belgians") and *Eer Belgenland* ("Honour to Belgium"), which, set to music, were much appreciated. He died at Schaerbeek, near Brussels, on the 27th of August 1899. Hiel's efforts to counteract Walloon influences and bring about a *rapprochement* between the Netherlanders in the north and the Teutonic racial sympathizers across the Rhine made him very popular with both, and a volume of his best poems was in 1874 the first in a collection of Dutch authors published at Leipzig. (H. Ti)

Hierapolis (1), Arabic *Manbij* or *Membij*, Turkish *Bembij*, occupying one of the finest sites in Northern Syria, in a fertile district, with an abundant water supply from large springs. In 1879, after the Russo-Turkish war, a colony of Circassians from Widin was planted in the ruins. (2) A Phrygian city, altitude 1100 feet, on the right bank of the Churuk Su (*Lycus*), about 8 miles above its junction with the Menderez (*Maeander*), situated on a broad terrace, 200 feet above the valley and 6 miles north of Laodicea. On the terrace rise warm, calcareous springs, that have deposited the vast incrustations of snowy whiteness from which the place gets its name, Pambúk Kalesi, "Cotton Castle." To these springs, which are slightly sulphureous, and to the Plutonium—a hole reaching deep into the earth, from which issued a mephitic vapour—the place owed its celebrity and sanctity. Here, at an early date, a religious establishment (*hieron*) existed, and the town which gradually grew round it became one of the greatest centres of Phrygian life. The chief religious festival was the Letoia, named after the goddess Leto, a local variety of the Mother Goddess (Cybele). Hierapolis was the seat of an early church (Col. iv. 13), with which tradition closely connects the Apostle Philip. It has been suggested by Professor Ramsay that the Plutonium, which had disappeared in the 4th century, was filled up and covered over by the Christians about A.D. 320.

Ramsay. *Cities and Bishoprics in Phrygia*, i. p. 84, &c. 1895. —Humann. *Altertümer von Hierapolis*. 1898. (C. W. W.)

Higginson, Thomas Wentworth (1823– ——), American author, reformer, and soldier, was born in Cambridge, Massachusetts, 22nd December 1823, being a descendant of Francis Higginson, minister of the church of Salem, Massachusetts, in 1629. He graduated at Harvard in 1841, and at the Harvard divinity school in 1847; entered the Unitarian ministry, and was pastor of churches in Newburyport and Worcester, Massachusetts, but left the ministry in 1858. Identifying himself with the anti-slavery movement, he was indicted for participation in the attempt to release Anthony Burns, a fugitive slave, in Boston in 1853; engaged in the effort to make Kansas a free state in 1856; sympathized with the abolitionist schemes of John Brown in 1859; and during the Civil War become colonel of the First South Carolina Volunteers, the first regiment recruited from former slaves who had been declared "contraband of war" by the Northern authorities. His army service continued until October 1864, when he resigned on account of a wound. His *Army Life in a Black Regiment* (1870) narrates his career and observations during his service in the field. At the conclusion of the war he devoted himself to literary work, first in Newport, Rhode Island, and then in his native place. His connexion with the periodical press has been constant. Many of his articles have been reissued in volumes. Of his books the best are *Out-Door Papers* (1863), a *Larger History of the United States* (1885), and *Cheerful Yesterdays* (autobiographical, 1898). During his whole life Colonel Higginson has been an ardent advocate of woman suffrage and "free religion," and in his later years left the Republican party, but continued to take part in politics as an Independent, and afterwards as a Democrat.

Highgate, a parish and district partly in the county of Middlesex and partly in the county of London, chiefly in the metropolitan borough of St Pancras. Highgate is situated on a hill (which reaches a height of 426 feet) on the Great North Road, 5½ miles north-west of the General Post Office. There are two chief ascents from London to the village of Highgate, viz., the West Hill and Highgate Hill, leading to the High Street. Holly Lodge, the residence of the Baroness Burdett Coutts, is on West Hill. Highgate is famous for mansions of historical interest, but several of them have been destroyed, such as Arundel House, where Bacon died in 1626, pulled down in 1825, and Andrew Marvell's cottage, cleared away in 1869. Cromwell House still exists, although a fire on 3rd January 1865 destroyed the upper floors. This mansion was presented by Oliver Cromwell to his eldest daughter, Bridget, on her marriage, 15th January 1646–47, with Henry Ireton. Lauderdale House, after many vicissitudes, is now the refreshment house of Waterlow Park. The site of the Grove was originally occupied by Dorchester House, the mansion of the marquis of Dorchester, a loyal adherent of Charles I. At No. 3, The Grove (the house of the late Mr James Gillman, surgeon), the poet Coleridge lived for eighteen years. The old burial ground (in which lie the remains of Coleridge) is under the college chapel. Highgate Archway, constructed in 1812 in order to make some

improvement in the roadway for the coaches travelling the Great North Road, has been rebuilt, and a new archway to carry a roadway 50 feet wide was completed in 1900. Near Whittington Stone, at the foot of Highgate Hill, are Whittington's Almshouses, removed from College Hill by the Mercers' Company. The association of Whittington with Highgate has, however, no authority in the original legend, for Bonehill or Bunhill is there designated as the place where he "turned again." Highgate can scarcely be said now to have any individual existence, and there are therefore no official statistics of the population of the place as a whole.

Highlands, formerly a city of Arapahoe county, Colorado, U.S.A., now a part of the city of Denver, on the west bank of the South Platte river, opposite Denver. Population (1890), 5161.

Higinbotham, George (1827–1893), Chief Justice of Victoria, sixth son of T. Higinbotham, of Dublin, was born on the 19th of April 1827, and educated at the Royal School, Dungannon, and at Trinity College, Dublin. After entering as a law student at Lincoln's Inn, and being engaged as reporter on the *Morning Chronicle* in 1849, he emigrated to Victoria, where he contributed to the *Melbourne Herald* and practised at the bar (having been "called" in 1853) with much success. In 1850 he became editor of the *Melbourne Argus*, but resigned in 1859 and returned to the bar. He was elected to the Legislative Assembly in 1861 for Brighton as an independent Liberal, was rejected at the general election of the same year, but was returned nine months later. In 1863 he became Attorney-General. Under the influence of Mr Higinbotham measures were passed through the Legislative Assembly of a somewhat extreme character; completely ignoring the rights and power of the Legislative Council, and the government was carried on without any Appropriation Act for more than a year. Mr Higinbotham, by his eloquence and earnestness, obtained great influence amongst the members of the Legislative Assembly, but his colleagues were not prepared to follow him as far as he desired to go. He contended that in a constitutional colony like Victoria the governor held the same position as the Sovereign in Great Britain, and that the Secretary of State for the Colonies had no right to fetter the discretion of the Queen's representative by any counsel or interference. Mr Higinbotham did not return to power with his chief, Sir James M'Culloch, after the defeat of the short-lived Sladen administration; and being defeated for Brighton at the next general election by a comparatively unknown man, he retired from politics and devoted himself to his large and lucrative practice at the bar. Amongst his other labours as Attorney-General he had codified all the statutes which were in force throughout the colony. In 1874 he was returned to the Legislative Assembly for Brunswick, but after a few months he resigned his seat. In 1880 he was appointed a puisne judge of the Supreme Court, and in 1886, on the retirement of Sir William Stawell, he was promoted to the office of Chief Justice. Mr Higinbotham was appointed president of the International Exhibition held at Melbourne in 1888–89, but did not take any active part in its management. One of his latest public acts was to subscribe a sum of £10, 10s. a week towards the funds of the strikers in the great Australian labour dispute of 1890, an act which did not meet with general approval. He died in 1893. (G. C. L.)

Hijar, a town of Eastern Spain, in the province of Teruel, on the right bank of the river Martin, situated in a plain. The neighbouring country produces wheat, wine, oils, fruit, and vegetables. The industries of Hijar are chiefly silk, linen, cotton, soap, and bricks. The principal structures are the parish church, the palace of the dukes of Hijar (title dating from 1268), and the town hall. Population (1897), 11,571.

Hilden, a town of Prussia, in the Rhine province, 9 miles south-east of Düsseldorf by rail. It has manufactures of silk, velvet, carpets, artificial wool, machinery, calico printing, and brickmaking. Population (1885), 7947; (1900), 11,301.

Hildesheim, a town and episcopal see of Prussia, province of Hanover, at the north foot of the Harz Mountains, 19 miles south-east of Hanover by electric railway. The 14th-century town hall was restored in 1883–92. The Knochenhauer House (1529), one of the finest examples of wooden architecture not only in Hildesheim, but in all Germany, was burnt in 1884, but has since been repaired. The Römer Museum, the geological section of which is especially noteworthy, is housed in the former church of St Martin's. New administrative offices were finished in 1888. Hildesheim is the seat of considerable industry, the chief productions being sugar, tobacco, vehicles, agricultural implements, gutta-percha wares, and bricks, and gardening is extensively carried on. Population (1885), 29,386; (1900), 42,973.

Hill, Octavia (1838–——) and **Miranda,** (1836–——), English philanthropic workers, were born in London, being daughters of Mr James Hill and granddaughters of Dr Southwood Smith, the pioneer of sanitary reform. They were brought up to take an interest in social problems, and Miss Octavia Hill's attention was early drawn to the evils of London housing, and the habits of indolence and lethargy induced in many of the lower classes by their degrading surroundings. As a result she conceived the idea of trying to free a few poor people from such influences, and Mr Ruskin, who sympathized with her plans, supplied the money for starting the work. For £750 Miss Hill purchased the 56 years' lease of three houses in one of the poorest courts of Marylebone. Another £78 was spent in building a large room at the back of her own house where she could meet the tenants. The houses were put in repair, cleansed, and let out in sets of two rooms. At the end of eighteen months it was possible to pay 5 per cent. interest, to repay £48 of the capital, as well as meet all expenses for taxes, ground rent, and insurance. What specially distinguished this scheme was that Miss Hill herself collected the rents, thus coming into contact with the tenants and helping to enforce regular and self-respecting habits. The success of her first attempt encouraged her to continue. Six more houses were bought and treated in a similar manner. A yearly sum was set aside for the repairs of each house, and whatever remained over was spent on such additional appliances as the tenants themselves desired. This encouraged them to keep their tenements in good repair. By the help of friends Miss Hill was now enabled to enlarge the scope of her work. In 1869 eleven more houses were bought, and gradually a band of helpers was trained to assist her. The plan was to set a visitor over a small court or block of buildings, to do whatever work in the way of rent collecting, visiting for the School Board, &c., was required. As years went on Miss Octavia Hill's work largely increased. Numbers of her friends bought and placed under her care small groups of houses, over which she fulfilled the duties of a conscientious landlord. Several large owners of tenement houses, notably the Ecclesiastical Commissioners, entrusted to her the management of such property, and consulted her about

plans of rebuilding; and a number of fellow-workers were trained by her in the management of houses for the poor. The results in Southwark (where Red Cross Hall was established) and elsewhere were very beneficial. Both Miss Miranda and Miss Octavia Hill have taken an interest in the movement for bringing beauty into the homes of the poor, and the former was practically the founder of the Kyrle Society, the first suggestion of which was contained in a paper read to a small circle of friends. Both sisters have worked for the preservation of open spaces, and helped to promote the work of the Charity Organization Society, and for several years Miss Miranda Hill has done admirable work in Marylebone as a member of the Board of Guardians.

Hiller, Ferdinand (1811–1885), German composer, was born at Frankfort-on-Main, 24th October 1811. Hiller was a link between the past era of great masters and the present. His first master was Aloys Schmitt, and when he was ten years of age his compositions and talent were so evidently above the average that his father, a well-to-do man, determined to send him to Hummel in Weimar. There he devoted himself to composition, among his work being the entr'actes to *Maria Stuart*, through which he made Goethe's acquaintance. Under Hummel, Hiller made great strides as a pianist, so much so that early in 1827 he went on a tour to Vienna, where he met Beethoven and produced his first quartet. After a brief visit home Hiller went to Paris in 1829, where he lived till 1836. His father's death necessitated his return to Frankfort for a time, but on 8th January 1839 he produced at Milan his opera *La Romilda*, and began to write his oratorio *Die Zerstörung Jerusalems*, one of his best works. Then he went to Leipzig, to his friend Mendelssohn, where in 1843–44 he conducted a number of the Gewandhaus concerts, and produced his oratorio. After a further visit to Italy to study sacred music, Hiller produced two operas, *Ein Traum* and *Conradin*, at Dresden in 1845 and 1847 respectively; he went as conductor to Düsseldorf in 1847 and Cologne in 1850, and conducted at the Opéra Italien in Paris in 1851 and 1852. At Cologne he became a power as conductor of the Gürzenich concerts and head of the Conservatorium. In 1884 he retired, and died 12th May in the following year. Hiller frequently visited England. He composed a work for the opening of the Royal Albert Hall, his *Nala and Damayanti* was performed at Birmingham, and he gave a series of pianoforte recitals of his own compositions at the Hanover Square Rooms in 1871. He had a perfect mastery over technique and form in musical composition, but his works are generally dry. He was a sound pianist and teacher, and occasionally a brilliant writer on musical matters. His compositions, numbering about two hundred, include six operas, two oratorios, six or seven cantatas, much chamber music, and a once-popular pianoforte concerto. (R. H. L.)

Hillsboro, capital of Hill county, Texas, U.S.A., on the Missouri, Kansas, and Texas, and the St Louis South-Western Railways. It is in the cotton region, and has local importance as a shipping and supply point. Population (1890), 2541; (1900), 5346, of whom 128 were foreign-born and 1751 were negroes.

Hilton, John (1804–1878), British surgeon, was born at Castle Hedingham, in Essex, in 1804, and was educated at Chelmsford, Boulogne-sur-Mer, and in Guy's Hospital, which he entered in 1824 (M.R.C.S. 1827, F.R.C.S. 1843). He was appointed demonstrator of anatomy in 1828, assistant-surgeon 1845, surgeon 1849. In 1867 he was President of the Royal College of Surgeons, and delivered the Hunterian oration. He was also surgeon-extraordinary to Queen Victoria. As Arris and Gale professor (1859–62) he delivered a course of lectures on "Rest and Pain," which have become classics. Hilton was the greatest anatomist of his time, and was nicknamed "Anatomical John." It was he who, with Towne the artist, enriched Guy's Hospital with its unique collection of models. In his grasp of the structure and functions of the brain and spinal cord he was far in advance of his contemporaries. As an operator he was more cautious than brilliant, and this was doubtless due partly to his living in the pre-anæsthetics period, and partly to his own consummate anatomical knowledge, as is indicated by the method for opening deep abscesses which is known by his name. But he could be bold when necessary; he was the first to reduce a case of obdurate hernia by abdominal section, and one of the first to practise lumbar colotomy. He died at Clapham on 14th September 1878.

Hilversum, a prosperous town in the province of North Holland, Netherlands, 10 miles north by east of Utrecht by rail. Formerly a small village with a Saxon population engaged in agriculture and linen-weaving (home industry), since 1848 it has become an industrial commune with thirty factories employing 800 workmen, mainly in the manufacture of floorcloths. It is a favourite place of residence for wealthy citizens of Amsterdam and Utrecht. In the vicinity are the Trompenberg sanatorium and the villages of Baarn and Soestdyk (with a royal summer palace). There are middle-class and technical schools. Population (1870), 6000; (1900), 19,442.

Himalaya.—Modern geographers restrict the term Himalaya to that portion of the mountain region between India and Tibet which is enclosed within the arms of the Indus and the Brahmaputra. From the bend of the Indus southwards towards the plains of the Punjab to the bend of the Brahmaputra southwards towards the plains of Assam, through a length of 1500 miles, is Himáleh or Himalaya. Beyond the Indus, to the north-west, the region of mountain ranges which stretches to a junction with the Hindu Kush south of the Pamirs is usually known as Trans-Himalaya. Thus the Himalaya represents the southern face of the great central upheaval—the plateau of Tibet—the northern face of which is represented by the Kuen Lun.

Structure of the Himalaya.

Throughout this vast space of elevated plateau and mountain face geologists now trace a system of main chains, or axes, extending from the Hindu Kush to Assam, arranged in approximately parallel lines, and traversed at intervals by main lines of drainage obliquely. Godwin-Austen indicates six of these geological axes as follows:—

(1) The main Central Asian axis, the Kuen Lun forming the northern edge or ridge of the Tibetan plateau.

(2) The Trans-Himalayan chain of Muztagh (or Karakoram), which is lost in the Tibetan uplands, passing to the north of the sources of the Indus.

(3) The Ladak chain, partly north and partly south of the Indus—for that river breaks across it about 100 miles above Leh. This chain continues south of the Tsanpo (or Upper Brahmaputra), and becomes part of the Himalayan system.

(4) The Zaskar, or main chain of the Himalaya, *i.e.*, the "snowy range" *par excellence*, indicated by Nanga Parbat (overlooking the Indus), and passing in a south-east direction to the southern side of the Deosai plains. Thence, bending slightly south, it extends to the line of snowy peaks which are seen from Simla and other hill stations. It leads past Chini to the famous peaks of Gangotri and Nanda Devi. This is the best known range of the Himalaya, and although its course eastwards to

the north of Nepal is not accurately traced, it probably includes Everest and Kanchinjunga in its stupendous array of snow-bound peaks ere it is merged in the mountains to the north of Assam.

(5) The outer Himalaya or Pir Panjal-Dhaoladhar ridge.

(6) The Sub-Himalaya, which is "easily defined by the fringing line of hills, more or less broad, and in places very distinctly marked off from the main chain by open valleys (dhúns) or narrow valleys, parallel to the main axis of the chain." These include the Siwaliks.

Interspersed between these main geological axes are many other minor ridges, on some of which are peaks of great elevation. In fact, the geological axis seldom coincides with the line of highest elevation, nor must it be confused with the main lines of water-divide of the Himalaya.

Accepting this general definition of the structure of the Himalaya, there is a certain amount of fresh matter of interest to be noted about many of these dominant features.

Present knowledge of the Himalaya.

The relation of the central Himalayan range (through which some of the most important rivers of the Indo-Gangetic plain force their way southwards) to that northern watershed of India which is lost in the Tibetan plateau is fully explained in the article HIMALAYA in the ninth edition of this Encyclopædia. South of this great central line of snowy peaks there is little to add to the information of twenty years ago, when the Dhúns and the Tarai and the valleys intersecting the outer Himalaya had been already examined so far as they lay within reach of examination. There were then wide Himalayan tracts which were not open to European exploration. Those tracts are for the most part still closed. Nepal, Bhutan, and the wild Mishmi and Abor hills to the north of the Assam valley are but partially mapped. On the other hand, Kashmir and the Kumaon and Garwhal districts have been closely surveyed, and the physiography of the little state of Sikkim is now well known. It is beyond the line of highest altitudes, to the eastern and western flanks of the great highlands of Tibet, that geographical exploration has lately been chiefly directed; and it is the physical relation between the Himalaya and these mountain borderlands enclosing the central plateau that still chiefly demands further elucidation.

The great northern watershed of India.

On the north and north-west of Kashmir the great water-divide which separates the Indus drainage area from that of the Yarkand and other rivers of Chinese Turkestan has been explored by Younghusband, and, more recently, by Deasy. The general result of their investigations has been to show that the Muztagh range, as it trends south-eastwards and finally forms a continuous mountain barrier together with the Karakoram, is the true water-divide west of the Tibetan plateau. Shutting off the sources of the Indus affluents from those of the Central Asian system of hydrography, this great water-parting is distinguished by a group of peaks of which the altitude is hardly less than that of the Eastern Himalaya, culminating in Mount Everest. Mount Godwin-Austen (28,278 feet high), only 730 feet lower than Everest, affords an excellent example in Asiatic geography of a dominating, peak-crowned watershed. From Kailas on the far west to the extreme north-eastern sources of the Brahmaputra, the great northern watershed of the Indo-Tibetan highlands has only been occasionally touched. Littledale, Du Rhins, and Bonvalot may have stood on it as they looked southwards towards Lhasa, but for some 500 or 600 miles east of Kailas it appears to be lost in the mazes of the minor ranges and ridges of the Tibetan plateau. Nor can it be said to be as yet well defined to the east of Lhasa, in spite of the enormous accession of information from Russian, American, French, and English sources which was gathered during the last twenty years of the 19th century concerning the northern face of the Tibetan plateau and the Tibeto-Chinese borderland.

Eastern Tibet.

The Tibetan plateau, or Chang, breaks up about the meridian of 92° E., and to the east of this meridian the affluents of the Tsanpo (the same river as the Dihong and subsequently to be known as the Brahmaputra) drain no longer from the elevated plateau, but from the rugged slopes of a wild region of mountains (of systematic conformation where its successive ridges are arranged in concentric curves around the great bend of the Brahmaputra), wherein are hidden the sources of all the great rivers of Burma and China. Neither immediately beyond this great bend, nor within it in the Himalayan regions lying north of Assam and east of Bhutan, have scientific investigations yet been systematically carried out; but we know that the largest of the Himalayan affluents of the Brahmaputra west of the bend derive their sources from the Tibetan plateau, and break down through the containing bands of hills, carrying deposits of gold from their sources to the plains, as do all the rivers of Western Tibet.

Himalaya north of the central chain of snowy peaks.

Although the northern limits of the Tsanpo basin are not sufficiently well known for us to locate the Indo-Tibetan watershed even approximately, there exists some scattered evidence of the nature of that strip of Northern Himalaya on the Tibeto-Nepalese border which lies between the line of greatest elevation and the trough of the Tsanpo. Recent investigations show that all the chief rivers of Nepal flowing southwards to the Tarai take their rise north of the line of highest crests, the "main range" of the Himalaya; and that some of them drain long lateral high-level valleys enclosed between minor ridges whose strike is parallel to the axis of the Himalaya and, occasionally, almost at right angles to the course of the main drainage channels breaking down to the plains. This formation brings the southern watershed of the Tsanpo to the immediate neighbourhood of the banks of that river. It also affords material evidence of that wrinkling or folding action which accompanied the process of upheaval, when the Central Asian highlands were raised, which is more or less marked throughout the whole of the north-west Indian borderland. North of Bhutan, between the Himalayan crest and Lhasa, this formation is approximately maintained; farther east, although the same natural forces first resulted in the same effect of successive folds of the earth's crust, forming extensive curves of ridge and furrow, the abundant rainfall and the totally distinct climatic conditions which govern the processes of denudation subsequently led to the erosion of deeper valleys enclosed between forest-covered ranges which rise steeply from the river banks.

Height of Himalayan peaks.

It may be noted that, although suggestions have been made from time to time of the existence of higher peaks north of the Himalaya than that which dominates the Everest group, there is no satisfactory evidence to support any such suggestion. Everest stands surrounded by pinnacles of such an altitude as make it difficult to detect its actual summit, which still ranks as the highest in the world. No satisfactory comparison of altitude can possibly be made except from a distance by means of trigonometrical observations. The mean of many such observations from the south-east has determined the height of Everest to be rather above 29,000 feet, and there is nothing to be seen beyond the group of pinnacles immediately sur-

rounding that peak which can compare with this altitude. Similar observations from the Tibetan plateau have hitherto been wanting; but recent travellers in Central Tibet have recorded nothing of greater altitude above the general level of the plateau (which may be taken at 15,000 feet) than 5000 or 6000 feet; and, looking southwards, have observed no distant peaks on the Nepal frontier which appeared to rival Everest. It is true that local native tradition, which regards Everest as a sacred mountain, seems to recognize some hitherto unmeasured higher peak in its neighbourhood; but it is obviously impossible that any conclusion could be formed as to the relative altitude of two unapproachable peaks from any position near the base of them. Such traditions are valueless.

Geological evolution of the Himalaya.

If the period 1880–1900 did not add much to our geographical knowledge of the Himalaya in those uncertain spaces where European exploration is impossible on account of political obstruction or the savage nature of the inhabitants, it led to much careful geological survey resulting in clearly-expressed opinions as to the conditions under which the mountain masses were evolved and their primary relations with the peninsula of India. The peninsula, which has been through countless ages of the past (since the close of the Palæozoic era) a land area, is now recognized as having included the Eastern Himalaya and the Assam hills in its periods of geological evolution; whilst the Western Himalaya belongs to that extra-peninsular area which has been repeatedly depressed beneath the sea up to the commencement of the Tertiary age. The older rocks of the Assam ranges are found to be closely related to those of the peninsula, and coal-bearing sandstones identical in character with those of the Bengal coalfields are found along the Himalaya from Sikkim eastwards.

In a remote geological age, at the commencement of the Cretaceous period, when a land connexion existed between South Africa and India, and the Maldive and Laccadive islands were prominent peaks defining a mountain range, the Eastern Himalaya appears to have been directly connected with the peninsula area without the intervening depression caused by the Gangetic plain. So far as we know, there are no marine deposits in the Eastern Himalaya, and it was part of the ancient Indian peninsula throughout the Palæozoic and Mesozoic ages, when all beyond the Aravalli range to the north-west was part of an ocean floor. The close of the Cretaceous period was the termination of a long period of repose and the commencement of another period of great earth movements which, gradually increasing in intensity, reached their maximum in the Pleiocene age, and are even now in process of reshaping the earth's surface, though with greatly diminished activity and force. The result of these movements was to drive back the sea, which covered all the north-western and northern trans-frontier of India, and to crush and fold the rocks, forcing them up into mountain ranges till marine limestones of nummulitic age have been raised to heights of 20,000 feet above the sea on the Himalaya; and sea-formed rocks of the trans-Indus frontier were compressed and crushed into jagged parallel lines of anticlinals, fringing a comparatively level surface of upheaved plateau. But there is direct evidence in the older composition of the rocks that the Himalayan upheaval was the result of a longer period of action and of earlier date than that of the Tertiary trans-Indus frontier hills. The immense mass of the Himalaya apparently precludes the possibility of elevation within the Tertiary period, and it seems probable that even so far back as the Pleiocene age it formed a mountain range not greatly inferior to that which now exists, and with the main drainage features marked out as at present. In those Tertiary beds, originally formed of river deposits and then tilted and compressed into the form of the Siwalik range flanking the foot of the Himalaya, are found beds of conglomerate and boulders close to the outlet of the modern rivers, proving that the ancient beds were not far from the modern channels, and that the rivers flowed much where they do now in the days when the gigantic mammals of Siwalik age roamed through the forests and plains that skirted the Himalayan foothills.

Indo-Gangetic depression.

Another result of those earth-movements which upheaved the Himalaya was the formation of the great parallel depression of the Indo-Gangetic plain. At first this depression had but one outlet, viz., by the Indus valley to the sea, but later the depression deepened between the Assam and Rajmahal hills, and through this channel Himalayan drainage was gradually diverted until, almost within historic times, the Jumna broke away eastwards instead of wandering in countless channels to the south and west, and established for ever the present water-divide between the Indus and Ganges. Such, briefly, is the general outline of Himalayan evolution as now understood, and the process of it has led to certain marked features of scenery and topography, to some of which allusion is made in the ninth edition of the *Encyclopædia Britannica*. The vast area of western trans-Indus hills has been raised above sea-level within the Tertiary period. Here we have beds of hard limestone or sandstone alternating with soft shales, which leads to the scooping out by erosion of long narrow valleys where the shales occur, and the passage of the streams through deep rifts or gorges across the hard limestone anticlinals, which stand in regular series of parallel ridges with the eroded valleys between.

The great mass of the Himalaya exhibits the same structure, due to the same conditions acting for a much longer period and on a much larger scale; but the structure is varied in the eastern portions of the mountains by the effect of different climatic conditions, and especially by the greater rainfall. Instead of wide, barren, wind-swept valleys, we here discover fertile alluvial plains—such as Manipur, for instance—but for the most part the erosive action of the river has been able to keep pace with the rise of the river bed, and we have deep, steep-sided valleys arranged between the same parallel system of folds as we see on the western frontier, connected by short transverse gaps where the rivers cross the folds, frequently to resume a course parallel to that originally held. An instance of this occurs where the Indus suddenly breaks through the well-defined Ladakh range in the North-west Himalaya to resume its north-westerly course after passing from the northern to the southern side of the range. The reason assigned for these extraordinary diversions of the drainage right across the general strike of the ridges is that it is antecedent—*i.e.*, that the lines of drainage were formed ere the folds or anticlinals were raised; and that the drainage has merely maintained the course originally held, by the power of erosion during the gradual process of upheaval.

In the outer valleys of the Himalaya the sides are generally steep, so steep as to be liable to landslip, whilst the streams are still cutting down the river beds and have not yet reached the stage of equilibrium. Here and there a valley has become filled with alluvial detritus owing to some local impediment in the drainage, and when this occurs there is usually to be found a fertile and productive field for agriculture. The straits of the Jhelam, below Baramulla, probably account for the lovely vale of Kashmir, which is in form (if not in principles of construction) a repetition on grand scale of the Maidán of the Afridi Tirah, where the drainage from the slopes of a great amphitheatre of hills is collected and then arrested by the gorge which marks the outlet to the Bara.

General Himalayan formation is typical.

Other rivers besides the Indus and the Brahmaputra commence by draining a considerable area north of the snowy range—the Sutlej, the Kosi, the Gandak, and the Sabansiri, for example. All these rivers break through the main snowy range ere they wind and twist their way through the southern hills to the plains of India. Here the "antecedent" theory will not suffice, for there is no sufficient catchment area north of the snows to support it. Their formation is explained by a process of "cutting back," by which the heads of these streams are gradually eating their way northwards owing to the greater rainfall on the southern than on the northern slopes. The result of this process is well exhibited in the relative steepness of slope on the Indian and Tibetan sides of the passes to the Indus plateau. On the southern or Indian side the routes to Tibet and Ladakh follow the levels of Himalayan valleys with no remarkably steep gradients till they near the approach to the water-divide. The slope then steepens with the ascending curve to the summit of the pass, from which point it falls with a comparatively gentle gradient to the general level of the plateau. The Zoji La, the Kashmir water-divide between the Jhelam and the Indus, is a prominent case in point, and all the passes from the Kumaon and Garwhal hills into Tibet exhibit this formation in a marked degree. Taking the average elevation of the central axial line of snowy peaks as 19,000 feet, the average height of the passes is not more than 10,000 owing to this process of cutting down by erosion and gradual encroachment into the northern basin.

Trans-Himalaya.

In comparison with the extent of geographical information which has been gained in the trans-frontier regions of the north-west of India, that which has been acquired during the period 1875–1900 about the Himalayan regions is small. The trans-Himalayan mountains about the head of the Gilgit valley, the sources of the Oxus, of the Kunar (or Chitral) river, and of the rivers of the Kashgar depression, have all been mapped, their glaciers and snowfields explored, and the difficult tracks and passes which intersect them examined; but in the Himalayan region, between the Indus and the Brahmaputra, it is doubtful if we know of a single new pass or mountain peak. From the western frontier of Nepal bordering Kumaon to Sikkim, for a distance of 180 miles along the length of the Nepal state, no fresh information has been gathered. Then Sikkim intervenes, and here for a short space we have extended geographical reconnaissance into surveys; but beyond Sikkim eastwards through Bhutan to the wild Assamese border hills we have nothing new to

record—not a new pass opened, nor a rudimentary exploration accomplished. This is due partly to the jealous watchfulness of the Nepalese authorities against the intrusion of strangers, which is maintained with rather increasing vigilance than otherwise, and to the wild and savage nature of the Assamese border tribes, who have not as yet been touched by civilizing influences. Consequently much of the Himalaya is still to us a region of conjecture, but of conjecture which is based on most careful study of neighbouring districts.

Glaciers. The northern tributaries of the Gilgit river, which joins the Indus near its south-westerly bend towards the Punjab, take their rise from a glacier system which is probably unequalled in the world for its extent and magnificent proportions. Chief amongst them are the glaciers which have formed on the southern slopes of the Muztagh mountains below the group of gigantic peaks dominated by Mount Godwin-Austen (28,278 feet high), the Golden Throne, and Masharbrum. The Biafo glacier system, which lies in a long narrow trough extending south-west from Nagar on the Hunza to near the base of the Muztagh peaks, may be traced for 90 miles between mountain walls which tower to a height of from 20,000 to 25,000 feet above sea-level on either side. The glaciers of the Himalaya have not yet been brought under systematic observation, but it is clear that there are no glaciers in the Himalaya to rival the trans-Indus group of the Muztagh. Griesbach's investigations of the chief glaciers of the Kumaon group show them to be of great extent. Nearly all the high valleys of the Himalaya possess glaciers. Near the Niti Pass leading from Almorá into Tibet there is a glacier 8 miles long; and Nanda Devi, one of the best known of the Central Himalayan group of snowy mountains, is surrounded by them. A glacier on the north side of Nanda Devi is 14 miles in length. The Gangotri group of peaks heading the Ganges sources are all surrounded with glaciers. Griesbach points out that the glaciers of the Central Himalaya are receding, and that they once extended to a much lower level than at present. This gradual diminution of glacial surface is equally apparent in trans-Himalayan regions.

Mountain scenery. Much has been written about the impressiveness of Himalayan scenery, and there is no need to repeat the observations of travellers who have described the countless phases of mountain landscape that are to be found within so vast a region subject to such variations of climatic influence. It is but lately, however, that any adequate conception of the magnitude and majesty of the most stupendous of the mountain groups which mass themselves about the upper tributaries and reaches of the Indus has been presented to us in the works of Younghusband, Conway, and Tanner. It is not in comparison with the picturesque beauty of European Alpine scenery that the Himalaya appeals to the imagination, for amongst the hills of the outer Himalaya—the hills which are known to the majority of European residents and visitors—there is often a striking absence of those varied incidents and sharp contrasts which are essential to picturesqueness in mountain landscape. Too often the brown, barren, sun-scorched ridges are obscured in the yellow dust haze which drifts upwards from the plains; too often the whole perspective of hill and vale is blotted out in the gray mists that sweep in soft, resistless columns against these southern slopes, to be condensed and precipitated in ceaseless monotonous rainfall. Few Europeans really see the Himalaya; fewer still are capable of translating their impressions into language which is neither exaggerated nor inadequate.

Some idea of the magnitude of Himalayan mountain construction —a magnitude which the eye totally fails to appreciate—may, however, be gathered from the following table of comparison of the absolute height of some peaks above sea-level with the actual amount of their slopes exposed to view:—

Relative Extent of Snow Slopes Visible.

Name of Mountain.	Place of Observation.	Height above sea.	Amount of Slope exposed.
Everest or Gaurisankar	Dewanganj . . .	29,000	8,000
,, ,,	Sandakphu . . .	,,	12,000
K_2 or Godwin-Austen .	Between Gilgit and Gor, 16,000 feet .	28,278	
Pk. XIII. or Makalu .	Purnea, 200 feet . .	27,800	8,000
,, ,, .	Sandakphu, 12,000 feet	,,	9,000
Nanga Parbat . .	Gor, 16,000 feet . .	26,000	23,000
Tirach Mir . . .	Between Gilgit and Chitral, 8000 feet .	25,400	17–18,000
Rakapushi . . .	Chaprot (Gilgit), 13,000 feet	25,560	18,000
Kanchinjunga . .	Darjiling, 7000 feet .	28,160	16,000
Mont Blanc . . .	Above Chamounix, 7000 feet	15,781	11,500

It will be observed from this table that it is not often that a greater slope of snow-covered mountain side is observable in the Himalaya than that which is afforded by the familiar view of Mont Blanc from Chamounix.

As regards the scenery surrounding the highest mountain in the world, Tanner says that the finest view of it which is obtainable from British territory is that which may be gained from Sandakphu, 35 miles from Darjiling. "The outline of Everest is rather tame, though fairly sharp, and a long snowy slope rests on its north-east flank. Peaks of 22,000 feet and thereabouts encircle its southern base, and below them are seen many dark mountain masses without snow. From due south, near the Kosi river in the Bhagalpur district, Everest is by no means a marked feature in the landscape; although from a near point of view its face is wild, and the cliff must be very lofty. . . . Though rising to a height of 29,000 feet, it only towers 12,000 feet above its fellows, and is thus relatively commonplace." He further points out that the Tibetans probably refer to Peak T 45 of the Indian Survey to the north-west of Everest, which rises to 27,000 feet, when they claim a higher peak than Everest. Its comparatively isolated position would produce the impression of greater altitude.

Kanchinjunga. For the picturesque beauty of its natural setting in the midst of tropical mountain scenery, no less than for grandeur of outline and profound impression of majestic predominance, there is probably no rival in the world to Kanchinjunga as seen from Darjiling. Here the forest splendours of the south combine with the ice-bound majesty of the north, and the two are linked by 16,000 feet of cloud-woven wreaths resting on the successive steps of the grandest mountain staircase that nature has ever fashioned.

Hill stations. The development of the "hill stations" of the Himalaya is naturally a point of interest in connexion with the general economic progress of India. Great efforts have been made since 1875 to render these stations, or towns, more accessible from the plains, with the result of an increasing population during those months of the year when the heat of the plains drives Europeans to the cool atmosphere of the mountains. It does not appear that the fixed and permanent population of hill stations is largely on the increase, although there is a distinct tendency towards native concentration in the neighbouring villages, and a visible spread of local cultivation in adjacent valleys. No marked increase of European colonists in the Himalaya, east of Kashmir, is recognizable, although the growing intermittent condensation of official society in the hill stations has called for increased house accommodation for temporary occupation. Indeed, the habitations of many of those European settlers who existed in days when communication with Europe was a matter of months now know them no more, and as a rule they have not been reoccupied. In the sheltered valley of Kulu, and on the outer slopes below Darjiling, fruit plantations and tea cultivation have been largely developed under European management; but with few exceptions the successful prosecution or agriculture does not lead to permanent settlements in the Himalaya. But the increased facilities for exchanging the close sultry atmosphere of the Indian plains in summer for the more invigorating (though frequently more humid) climate of "the hills" have developed a temporary European population of thousands in places (as in Simla) where there used to be hundreds not so very long ago, and have demanded still further efforts towards facilitating communications.

Mountain railways. At Darjiling a mountain railway of 51 miles in length already connects that station with the Bengal railway system, but this is the only hill station of the Himalaya which in the year 1900 enjoyed such facilities of approach. Railway projects are already sanctioned for connecting Srinagar in Kashmir with the Punjab, and Simla with the head of the Delhi-Kalka line; and the road to Mussoorie will be shortened by a line which will connect Dehra-Dun at the foot of the Mussoorie hills with the sanitarium on their summits. These short local mountain lines would have been constructed earlier had the trade from the hill regions to the plains been sufficient to justify them, but trade with the interior across the Himalayan passes has shown little signs of development. Trade from High Asia across the group of passes which head the rivers of Kumaon and Garwhal, as well as that by the Sutlej river route through Simla, has rather diminished than increased of late years. In Kashmir alone there has sprung up a considerable local traffic (chiefly in fruit), and between Tibet and Kashmir *viâ* Ladak there seems to be promise for the future.

Authorities.—Our old authorities on the Himalaya (notably the Stracheys, Hooker, and Blanford) are still the best, but we have had a good many popular contributions to the subject since 1875, amongst which the following are the best known:—Drew. *Jammu and Kashmir.* London, 1875.—Leitner. *Dardistan.*—Biddulph. *Tribes of the Hindu Kush.* Calcutta, 1880.—Lydekker. "Geology of Kashmir, &c." Vols. xiii. and xiv. *Geological Survey of India.*—Godwin-Austen. "Mountain Systems of the Himalaya." Vols. v. and vi. *Proc. R. G. S.*,

1883-84.—UJFALVY. *Aus dem westlichen Himalaya.* Leipzig, 1884.—TANNER. "Our Present Knowledge of the Himalaya." Vol. xiii. *Proc. R. G. S.*, 1891.—GRIESBACH. "Geology of Central Himalaya." *Geological Survey Memoirs.* Calcutta, 1891.—OLDHAM. "The Evolution of Indian Geography." Vol. iii. *Jour. R. G. S.*—LAWRENCE, W. *Kashmir.* Oxford, 1895.—CONWAY. *Climbing and Exploring in the Karakoram.* London, 1898. (T. H. H.*)

Hindley, a township in the Ince parliamentary division of Lancashire, England, 2 miles east-south-east of Wigan, on the Lancashire and Yorkshire and the London and North-Western Railways. It has a free library and museum. Area of township (an urban district), 2611 acres. Population (1881), 14,715; (1901), 23,504.

Hindu Kush, a range of mountains, throughout 500 miles of its length, from its roots in the Pamir regions till it fades into the Koh-i-Baba to the west of Kabul, forming the water-divide between the Kabul and the Oxus basins, and, for the first 200 miles, reckoning westwards, the southern boundary of Afghanistan. It may be said to spring from the head of the Taghdumbash Pamir, where it unites with the great meridional system of Sarikol stretching northwards, and the yet more impressive mountain barrier of Muztagh, the northern base of which separates China from the semi-independent territory of Kanjut. The Wakhjir pass, crossing the head of the Taghdumbash Pamir into the sources of the river Hunza, almost marks the tri-junction of the three great chains of mountains. As the Hindu Kush strikes westwards, after first rounding the head of an Oxus tributary (the Ab-i-Panja, which Curzon considers to be the true source of the Oxus), it closely overlooks the trough of that glacier-fed stream under its northern spurs, its crest at the nearest point being separated from the river by a distance which cannot much exceed 10 miles. As the river is here the northern boundary of Afghanistan, and the crest of the Hindu Kush the southern boundary, this distance represents the width of the Afghan kingdom at that point.

Physiography.—For the first 100 miles of its length the Hindu Kush is a comparatively flat-backed range of considerable width, permitting the formation of small lakes at intervals on the crest, and possessing no considerable peaks. It is crossed by many passes, varying in height from 12,500 feet to 17,500 feet, the lowest and the easiest being the well-known group about Baroghél, which has from time immemorial offered a line of approach from High Asia to Chitral and Jalalabad. As the Hindu Kush gradually recedes from the Ab-i-Panja and turns south-westwards it gains in altitude, and we find prominent peaks on the crest which measure more than 24,000 feet above sea-level. Even here, however, the main central water-divide, or axis of the chain, is apparently not the line of highest peaks, which must be looked for to the south, where the great square-headed giant called Tirach Mir dominates Chitral from a southern spur. For some 40 or 50 miles of this south-westerly bend, bearing away from the Oxus, where the Hindu Kush overlooks the mountain wilderness of Badakshan to the west, the crest is intersected by many passes, of which the most important is the Dorah group (including the Minján and the Mandal), which rise to about 15,000 feet, and which are, under favourable conditions, practicable links between the Oxus and Chitral basins.

Kafiristan Section.—From the Dorah to the Khawák pass (or group of passes, for it is seldom that one solitary line of approach only is to be found across the Hindu Kush), which is between 11,000 and 12,000 feet in altitude, the water-divide overlooks Kafiristan and Badakshan. Here its exact position is matter of conjecture. It lies amidst a wild, inaccessible region of snow-bound crests, and is certainly nowhere less than 15,000 feet above sea-level. There is a tradition that the great Timur attempted the passage of the Hindu Kush by one of the unmapped passes hereabouts, and that, having failed, he left a record of his failure engraved on a rock in the pass.

Passes.—The Khawák, at the head of the Panjshir tributary of the Kabul, leading straight from Badakshan to Charikar and the city of Kabul, is now an excellent khafila route, the road having been engineered under the Amir's direction, and it is said to be available for traffic throughout the year. From the Khawák to the head of the Ghorband (a river of the Hindu Kush which, rising to the north-west of Kabul, flows north-east to meet the Panjshir near Charikar, whence they run united into the plains of Kohistan) the Hindu Kush is intersected by passes at intervals, all of which were surveyed, and several utilized, during the return of the Russo-Afghan Boundary Commission from the Oxus to Kabul in 1886. Those utilized were the Kaoshán (the "Hindu Kush" pass *par excellence*), 14,340 feet; the Chahardar (13,900 feet), which is a link in one of the Amir of Afghanistan's high roads to Turkestan; and the Shibar (9800 feet), which is merely a diversion into the upper Ghorband of that group of passes between Bamián and the Kabul plains which are represented by the Irák, Hajigak, Unai, &c. About this point it is geographically correct to place the southern extremity of the Hindu Kush, for here commences the Koh-i-Baba system into which the Hindu Kush is merged.

General Conformation.—The general conformation of the Hindu Kush system south of the Khawák, no less than such fragmentary evidence of its rock composition as at present exists to the north, points to its construction under the same conditions of upheaval and subsequent denudation as are common to the western Himalaya and the whole of the trans-Indus borderland. Its upheaval above the great sea which submerged all the north-west of the Indian peninsula long after the Himalaya had massed itself as a formidable mountain chain, belongs to a comparatively recent geologic period, and the same thrust upwards of vast masses of Cretaceous limestone has disturbed the overlying recent beds of shale and clays with very similar results to those which have left so marked an impress on the Baluch frontier. Successive flexures or ridges are ranged in more or less parallel lines, and from between the bands of hard, unyielding rock of older formation the soft beds of recent shale have been washed out, to be carried through the enclosing ridges by rifts which break across their axes. The Hindu Kush is, in fact, but the face of a great upheaved mass of plateau land lying beyond it northwards, just as the Himalaya forms the southern face of the great central tableland of Tibet, and its general physiography, exhibiting long, narrow, lateral valleys and transverse lines of "antecedent" drainage, is similar. There are few passes across the southern section of the Hindu Kush (and it should be noted that this section is, from the politico-geographical point of view, more important to India than the whole Himalayan system) which have not to surmount a succession of crests or ridges as they cross from Afghan Turkestan to Afghanistan. The exceptions are, of course, notable, and have played an important part in the military history of Asia from time immemorial. From a little ice-bound lake called Gaz Kul, or Karambar, which lies on the crest of the Hindu Kush near its northern origin at the head of the Taghdumbash Pamir, two very important river systems (those of Chitral and Hunza) are believed to originate. The lake really lies on the watershed between the two, and is probably a glacial relic. Its contribution to either infant stream appears to depend on conditions of

overflow determined by the blocking of ice masses towards one end. It marks the commencement of the water-divide which primarily separates the Gilgit basin from that of the Yashkun, or Chitral, river, and subsequently divides the drainage of Swat and Bajaor from that of the Chitral (or Kunar). The Yashkun-Chitral-Kunar river (it is called by all three names) is the longest affluent of the Kabul, and it is in many respects a more important river than the Kabul. Throughout its length it is closely flanked on its left bank by this main water-divide, which is called Moshabar or Shandur in its northern sections, and owns a great variety of names where it divides Bajaor from the Kunar valley. It is this range, crowned by peaks of 22,000 feet altitude and maintaining an average elevation of some 10,000 feet throughout its length of 250 miles, that is the real barrier of the north—not the Hindu Kush itself. Across it, at its head, are the glacial passes which lead to the foot of the Baroghél. Of these Darkot, with a glacial staircase on each side, is typical. (See Gilgit.) Those passes (the Kilik and Mintaka) from the Pamir regions, which lead into the rocky gorges and defiles of the upper affluents of the Hunza to the east of the Darkot, belong rather to the Muztagh system than to the Hindu Kush. Other passes across this important water-divide are the Shandur (12,250 feet), between Gilgit and Mastuj; the Lowarai (10,450 feet), between the Panjkora and Chitral valleys; and farther south certain lower crossings which once formed part of the great highway between Kabul and India.

Chitral.—Deep down in the trough of the Chitral river, about midway between its source and its junction with the Kabul at Jalalabad, is the village and fort of Chitral. The village is insignificant, and the fort derives its notoriety from the siege of 1895, when it proved to be defensible with difficulty against an undisciplined highland rabble who were without artillery. Facing Chitral, on the right bank of the river, and extending for some 70 miles from the Hindu Kush, is the lofty snow-clad spur of the Hindu Kush known as Shawal, across which one or two difficult passes lead into the Bashgól valley of Kafiristan. This spur carries the boundary of Afghanistan southwards to Arnawai (some 50 miles below Chitral), where it crosses the river to the long Shandur watershed. South of Arnawai the Kunar valley becomes a part of Afghanistan (see Kunar). Chitral can be reached either by the long circuitous route from Gilgit, involving 200 miles of hill roads and the passage of the Shandur pass (12,250 feet), or (more directly) from the Peshawar frontier at Malakand by 100 miles of route through the independent territories of Swat and Bajaor, involving the passage of the Lowarai (10,450 feet). It is held at present by a small force as a British outpost. The district of Chitral is called Kashkar (or Kashgar) by the people of the country; and as it was once under Chinese domination, and was regarded as a Buddhist centre of some importance by the Chinese pilgrims in the early centuries of our era, it is possible that it then existed as an outlying district of the Kashgar province of Chinese Turkestan, where Buddhism once flourished in cities that have been long since buried beneath the sand-waves of the Takla Makan. The aboriginal population of the Chitral valley is probably to be recognized in the people called Kho (speaking a language called Khowar), who form the majority of its inhabitants. It is from this Kho community that Sir H. Yule considered it likely that the ancient classical name of Khoaspes for the river of Chitral was derived. Upon the Kho a people called Ronas have been superimposed. The Ronas, who form the chief caste and fighting race of the Chitral districts, originally came from the north, but they have adopted the language and fashions of the conquered Chitrali. Chitral may be regarded as an outlying branch of the Gilgit political agency, which is itself a branch of Kashmir administration, its political status being "independent." The value of Chitral as an outpost of British India may be best gauged by its geographical position. It is about 100 miles (direct map measurement) from the outpost of Russia at Langar Kisht on the river Panja, with the Dorah pass across the Hindu Kush intervening. The Dorah may be said to be about half-way between the two outposts, and the mountain tracks leading to it on either side are rough and difficult. The Dorah, however, is not the only pass which leads into the Chitral valley from the Oxus. The Mandal pass, a few miles south of the Dorah, is the connecting link between the Oxus and the Bashgól valley of Kafiristan; and the Bashgól valley leads directly to the Chitral valley at Arnawai, about 50 miles below Chitral. Nor must we overlook the connexion between north and south of the Hindu Kush which is afforded by the long narrow valley of the Chitral (or Yashkun) itself, leading up to the Baroghél pass. This is the route which was once made use of by the Chinese for purposes of pilgrimage, if not for invasion. Access to Chitral from the north is therefore but a matter of practicable tracks, or passes, in two or three directions, and the measure of practicability under any given conditions can best be reckoned from Chitral itself. By most authorities the possibility of an advance in force from the north, even under the most favourable conditions, is considered to be exceedingly small; but the tracks and passes of the Hindu Kush are only impracticable so long as they are left as nature has made them. (See Chitral.)

Our information about the Hindu Kush and Chitral is now comparatively exact. The Russo-Afghan Boundary Commission of 1884 and the Chitral Expedition of 1895 opened up a vast area for geographical investigation, and the store of information collected is to be found in the reports and gazetteers of the Indian Government. The following are the chief recent authorities:—Report of the Russo-Afghan Boundary Commission, 1886; Report of Lockhart's Mission, 1886; Report of Asmar Boundary Commission, 1895; Report of Pamir Boundary Commission, 1896. Proc.*, 1892.—Colonel Durand. *Making a Frontier.* London, 1899.—Sir G. Robertson. *Chitral.* London, 1899.

(T. H. H.*)

Hindu Law.—The Hindu law is that body of law which is administered by the courts of British India when they are dealing with Hindus. It is not a territorial law applicable to all persons in British India, but a personal law applicable to Hindus only. And even for Hindus the Hindu law which is administered to-day does not cover the whole field of jurisprudence. There are many laws, some made by the British Parliament, some by the legislative bodies in India, and some which have grown up under the decisions of the courts, which are applicable to Hindus as well as to other British subjects in India.

The extent to which Hindu law is administered by the British courts in India, and the circumstances by which that extent has been determined, can only be explained by a short recapitulation of the events which led to these courts being established. Prior to 1771 the only British courts in India were those in Calcutta, Bombay, and Madras, established by royal charter and administering English law. In 1772, Warren Hastings, as Governor-General in council, acting, not under any authority derived from the British Government, but under the authority conferred upon the East India Company by the Mogul emperor, drew up a series of regulations for the administration of civil justice in Bengal, Behar, and Orissa. At that time the

law which prevailed in those districts in civil matters was as regards Hindus the Hindu law, as regards Mahommedans the Mahommedan law. The criminal law as regards all persons was the Mahommedan law, but jurisdiction in criminal matters was reserved by the emperor to his own officers, and did not pass to the East India Company until later. The form in which the authority of the emperor was granted was that of appointing the East India Company to be the "Dewan," or chief civil officer, in Bengal, Behar, and Orissa. This authority was, of course, exercised by the Company through the Governor-General in council. What were the exact limits of this authority it would not be very easy to determine, for though in theory the East India Company were the servants of the emperor, all the substantial power lay with the Company, and probably Hastings did not consider very closely what the exact limits of his authority were. What he actually announced in the Regulations by which he constituted the courts in the above districts, was that "in all suits regarding inheritance, marriage, caste, and other religious usages and institutions, the laws of the Koran with respect to Mahommedans and those of the Shasters with respect to Gentoos [*i.e.*, Hindus] shall be invariably adhered to." What law was to be applied in other cases the Regulations did not say, but it must be remembered that the topics of litigation at that time were very few.

Shortly after this, namely, in 1773, the Supreme Court was established in Calcutta under the authority of Parliament. There arose out of this a conflict between the Governor-General in council and the Supreme Court, on account of the latter claiming jurisdiction outside Calcutta, to which the officers of the East India Company refused to submit. This dispute was settled by the statute 21 Geo. III. c. 70, which confined the jurisdiction of the Supreme Court to Calcutta, and declared that the "inheritance and succession to lands, rents, and goods, and all matters of contract and dealing between party and party, shall be determined in the case of Mahommedans by the laws and usages of the Mahommedans, and in the case of Gentoos [*i.e.*, Hindus] by the laws and usages of Gentoos." In matters of contract the native laws have never been much regarded, and, except where any special custom can be proved, the whole matter is now governed by the Contract Act. The old legislative enactments have also been superseded. By Act 111 of 1887, § 37, the law to be administered in the civil courts in Bengal, the North-West Provinces, and Assam is laid down in these terms:—"Where in any suit or other proceeding it is necessary for a civil court to decide any question regarding succession, inheritance, marriage, or caste, or any religious usage or institution, Hindu law in cases where the parties are Hindus shall form the rule of decision, except in so far as such law has by legislative enactment been altered or abolished"; and there are statutory provisions in similar terms for other parts of India. The interpretation put upon the provisions of the Indian Regulations quoted above, the British Act of Parliament, and the later Indian Acts have been substantially the same.

Sources of Hindu Law.—The Hindu law is in theory of divine origin, and therefore unchangeable by human authority. Ask a Hindu where his law is to be found, and he will reply "In the Shasters." The Shasters are certain books supposed to be divinely inspired, and all of great antiquity. They contemplate a state of society very unlike that of the present day, or that of many centuries back. It follows that these sacred writings, whilst they leave many of the legal requirements of the present day wholly unprovided for, contain many provisions which no Hindu even would now think of enforcing. Consequently, in spite of the theory, the law had to be changed. Legislation, which with us is the most potent as well as the most direct instrument of change, has had scarcely any effect on the Hindu law. Probably it never entered into the head of any Hindu before British rule was set up in India that any human agency could be entrusted with the power of making or changing the law; and although both the Indian Legislatures and the British Parliament have full power to legislate for Hindus upon all matters without any exception, they have, in fact, hardly ever exercised this power as regards the Hindu law. Custom is a less direct instrument of change than legislation, and operates more slowly and secretly, but its influence is very great. The custom which supplants the sacred law may indeed be as old as or older than the sacred law, and its existence may be due to the divinely inspired law having failed to displace it; or the habits and necessities of the people may have engrafted the custom upon the sacred law itself. In either view there has been no difficulty in accepting custom where it varied from the sacred law. Indeed, the sacred books themselves recognize to some extent the operation of custom. Thus we find it said in the Laws of Manu (viii. 4, 1), "the king who knows the sacred law must inquire into the laws of castes, of districts, of guilds, and of families, and thus settle the peculiar law of each." It is to the influence of custom that the divergence between the Hindu law of to-day and that of the Shasters is largely due. Another method by which law is developed, and one more subtle still, is interpretation; and it is one which in skilful hands may be used with considerable effect. Without any dishonesty, people very often find in the language of the law words sufficiently vague and comprehensive to cover the sense which they are looking for. The action of interpretation upon Hindu law differs accordingly as it took place before or after the British occupation. Formerly the only persons whose interpretation was accepted as authoritative were the writers of commentaries. But the Indian courts are very sparing in accepting modern commentaries as authoritative, though nevertheless they carefully record their own interpretations of the law, and these are always treated as authoritative. It follows, from the very nature of the influences thus brought to bear upon law, that not only have the sacred books been departed from, but that different results have been arrived at in different parts of India. The differences have led recent writers to speak of five schools of Hindu law, called respectively the Benares school, the Bengal or Gauriya school, the Bombay school or school of Western India, the Dravida school or school of Southern India, and the Mithila school—the district last named being a very small one to the south of and adjoining Nepal. But it would be a great mistake to suppose that the differences between these so-called schools are comparable to each other in importance. As will appear presently, it would be much more correct to speak of two schools, that of Benares and that of Bengal—the other three being subdivisions of the first.

Sacred Books.—It will be convenient to give a short description of those of the sacred books which are actually in use in the Indian courts when they desire to ascertain the Hindu law. Of these by far the first in importance, as well as the first in date, is the one which we call the Laws of Manu. It has been translated by Professor Buhler, and forms vol. xxv. of the "Sacred Books of the East," edited by Professor Max Müller. If we examine it, we find that only about one-fourth of the book deals with matters which we should call legal, the rest being concerned with topics either purely religious or ceremonial. And of these topics only one, that relating to partition of family property, belongs to that portion of

the Hindu law which is administered in the courts, and, as one would expect, what is said on this topic has been largely departed from under the influences above described. Very little is known as to the date of the Laws of Manu. They are probably much older than their present form, which Buhler places somewhere between 200 B.C. and A.D. 200. Of more interest than the exact date is the state of society which they disclose. The tribal and nomadic stage had passed away. Society had so far settled down as to possess a regular form of government under a king. The people were divided into four great castes, representing religion, war, commerce and agriculture, and servitude. Justice is spoken of as administered by the king. Provision is made for the recovery of debts and the punishment of offences. There are rules relating to the pasture of cattle, trespass by cattle, and the enclosure of cultivated fields. There was evidently considerable wealth in the shape of horses, carriages, clothes, jewellery, and money. There is no mention of land in general as the subject of permanent private property, though no doubt the homestead and the pasture land immediately adjoining were permanently owned.

The (so-called) Smriti of Yajnavalkya was, no doubt, a work of considerable importance in its day, and is still sometimes referred to. It shows a somewhat more advanced state of society than the Laws of Manu. The occupier of land has a firmer hold upon it, and there seems to be even a possibility of transferring land by sale. The date of it has not been fixed, but it is thought to be later than the Laws of Manu.

The Smriti of Narada belongs to a still later period, perhaps to the 5th or 6th century of our era. It goes more into detail than the other two books just mentioned.

But far more important for practical purposes than these sacred books are the commentaries. These are not sacred. The most important of them all is that known as the Mitacshara. The author of it was named Vijnaneswara. His work is a commentary on the Smriti of Yajnavalkya, and it is supposed to have been written in the latter half of the 11th century. Only a portion of it is used by the law courts—that portion which relates to the partition of family property. It is easy to see that in the eight or ten centuries which had elapsed since the date of the Laws of Manu, society had considerably advanced, and that the law has undergone great changes. The Mitacshara is an important authority for Hindus all over India, and in the greater part its authority is supreme. But there is one very important exception. In the district which is sometimes called Bengal Proper (from its correspondence with the ancient kingdom of Bengal, of which Gaur was the capital), and may be roughly described as the valley of the Ganges below Bhagalpur, the prevailing authority is a treatise called the Dayabhaga. It is, like the Mitacshara, as its name imports, a treatise on partition. The author of it was Jimutavahana. There does not appear to be any more distinct clue to its date than that this author wrote after the 12th century and before the 16th. The very important points of difference between the two commentaries will be stated hereafter. In Western India there is a commentary of authority called the Vyavahara Mayukha. It belongs to the 16th century. Generally its authority is secondary to that of the Mitacshara, but in Gujrat its authority is to some extent preferred. In the south of India the Smriti Chandrika is a work of importance. It belongs to the 13th century. It generally follows the Mitacshara, but is fuller on some points. The Vivada Chintamani is used in the small district of Mithila. It is said to belong to the 15th century.

The Joint Family.—The joint family is by far the most important institution of Hindu society, and it is only through the joint family that we can form a proper conception of the Hindu law. It is the form in which the patriarchal system has survived in India. There is nowhere in Hindu literature, ancient or modern, a description of it as it has existed at any time. In its general features it has always been too universal and too well known to be described. In the Laws of Manu we find very little about it, but what we do find is of great interest. The subject is taken up with reference to a question which in every patriarchal system imperatively requires an answer. What is to be done when a break-up of the family is threatened by the death of the common ancestor? Upon this subject the author of the Laws of Manu says in chap. ix. v. 104: "After the death of the father and the mother, the brothers being assembled, may divide among themselves in equal shares the paternal estate, for they have no power over it while the parents live." Then in v. 105, "or the eldest son alone may take the whole paternal estate; the others shall live under him just as they lived under the father." And in v. 111, "Either let them thus live together, or apart if each desires to gain spiritual merit, for by their living separate merit increases, hence separation is meritorious."

We may put aside what is said about the mother, which is probably a survival of polyandry, and is now obsolete, and fix our attention upon three important points:—(1) Authority is attributed to the father during his life; (2) the same absolute authority is attributed to the eldest son upon the father's death, if the family remains undivided; (3) the sons are at liberty, are indeed recommended, to divide the property. Now, though there may be doubts as to how far this type of family was at any time the universal one, there cannot be any doubt that in those early times it largely prevailed, and that the modern Hindu joint family is directly derived from it. Moreover, it must be remembered that what is here discussed is not ownership, but managership. If the family remained undivided, the eldest son did not take the family property as owner; he only became the uncontrolled manager of it. So far as there was any notion of ownership of the family property, and it was in those early times quite rudimentary, it was in the nature of what we call corporate ownership. The property belonged not to the individual members of the family collectively, but to the family as a whole; to use a modern illustration, not to the members of a family as partnership property belongs to partners, but as collegiate property belongs to fellows of a college. Probably, however, in early times it never occurred to any one to look very closely into the nature of ownership, for until the question of alienation arises the difference between managership and ownership is not of very great importance; and this question did not arise until much later. When and under what circumstances Hindus first began to consider more carefully the nature of ownership we have no means of ascertaining. But we have very clear evidence that there was at one time a very warm controversy on the subject. Each of the two leading commentaries on Hindu law, the Mitacshara and the Dayabhaga, opens with a very long discussion as to when and how a son becomes entitled to be called an owner of the family property. Two conflicting theories are propounded. One is that the sons are joined with the father in the ownership in his lifetime; the other is that they only become owners when he dies, or relinquishes worldly affairs, which, according to Hindu ideas, like taking monastic vows, produces civil death. The author of the Mitacshara adopts the first of these views; the author of the Dayabhaga adopts the second;

and this radical difference led to the great schism in the Hindu law. It follows that, according to the Dayabhaga view, the sons not being owners, the father is sole owner. He is both sole owner and uncontrolled manager. According to the Mitacshara view the father and the sons together are the owners, not as individuals, but as a corporation. But even this is not inconsistent with the father retaining his absolute control as manager. How far he has done so will be considered presently.

Hitherto, for the sake of simplicity, the position of father and son has alone been considered; but now take the case of several brothers living together with sons and grandsons. What is the nature of the ownership in this case, and in whom is it vested? Neither in the Dayabhaga nor in the Mitacshara is this question discussed directly, but each of these commentaries discloses the answer which its author would give to this question. According to the Mitacshara, of however many different branches, and of however many different members, a family may consist, they all form a single unity or corporation to which the family property belongs. Not that this is asserted in so many words; there is probably no Sanskrit word corresponding at all nearly to our word corporation. But this is the only language in which a modern lawyer can describe the situation. The members of the family are not partners; no one can separately dispose of anything, not even an undivided share. It is quite otherwise under the Dayabhaga. The property belongs to the members of the family, not as a corporation, but as joint owners or partners. Each is the owner of his undivided share; but not all the members of the Dayabhaga family have a share in the ownership; the sons whose fathers are alive are entirely excluded: the owners are those members of the family of any age who have no direct living ancestor.

This was the nature of family ownership in its two principal forms, but the possibility that an individual member of the family could have something exclusively his own is clearly recognized in the Laws of Manu. Thus in chap. ix. v. 206, it is said, "Property acquired by learning belongs solely to him to whom it was given, likewise the gift of a friend, a present received in marriage, or with the honey mixture." And again in v. 208, "What the brother may acquire by his labour without using the patrimony, that acquisition made solely by his own effort he shall not share, unless by his own will, with his brothers"; and these texts, as we shall see presently, are still of practical application. Nowhere has a strict family system prevailed without some analogous measure of relief. In Rome we find the *peculium*. In England, as late as the 13th century, lawyers speak of the *allod*, or ancient inalienable family domain, sometimes called *hereditas*, side by side with the *questum*, or acquired property. And Sir Henry Maine considers that there is something analogous in the ancient Brehon law (see *Early History of Institutions*, p. 110).

The modern Hindu joint family is a community the members of which are all descended from a common ancestor, and the wives and unmarried daughters of those who are married. Perhaps the wives and daughters might more correctly be said to belong to the family than to be members of it. In its complete form the family is said to be joint in food, worship, and estate; and notwithstanding the divergence between the Mitacshara and Dayabhaga systems, the main external features of such a family are the same all over India. Every Hindu family has a common home. This does not mean that there is a single house in which all the members of the family continuously reside, but there is one house where the family gods remain, where the wants of all the members of the family are provided for, where the family worship is conducted, and to which every member of the family is at any time at liberty to resort. This is the real home of a Hindu. Any other residence, however long it may last, is looked upon as temporary. Here also the wives and children remain whilst the men are employed at a distance. With regard to the enjoyment of the family property there is no distinction, except such as the members of the family themselves choose to make. Everything is enjoyable in common. This is the same all over India. It is very necessary to distinguish between ownership and enjoyment. Although the ownership of the family property under the Mitacshara differs very materially (as explained above) from that under the Dayabhaga, the enjoyment in both cases is the same. There is one common fund out of which the wants of the family are supplied. No one is dependent upon his own contribution to the family fund. No one member can say to another, "You have consumed more than your share, and you must make it good." On the other hand, whatever is earned goes into the common stock. Though separate acquisition is possible, it is exceptional, and there is always a presumption that the earnings of all the members belong to the common fund, so that if any member claims property as self-acquired he must establish his assertion by evidence as to how he acquired it, and that he did so "without using the patrimony." The accounts of the family are kept by the manager, who is usually the eldest male, and he also generally manages the property. But he is assisted and controlled by the other members of the family. No separate account is kept of what each member contributes or receives. The expenditure on behalf of the various members of the family is scarcely ever equal, but this inequality creates no debt between the members of the family. If any one is dissatisfied he can protest, and if his protest is not listened to, there is only one remedy—he can demand a partition. The powers of the manager are those of an agent: it is very rare to find them formally expressed, and they must be gathered from the usual course of dealing, either amongst Hindus generally, or in the particular family to which the manager belongs; and it is the custom for all the adult male members of the family to be consulted in matters of serious importance. The alienation of land is always looked upon as a matter of special importance, and, except in cases of urgent necessity, requires the express assent of all the members of the family.

Partition.—If any member of a Hindu family who is one of the co-owners wishes for a partition, he can demand one, there never having been any compulsion on the members of a Hindu family to live in common. Of course in a Dayabhaga family there can only be a partition as between brothers, or the descendants of brothers; between a father and his sons there can be no partition, the sons not being owners. The father may, if he chooses to do so, distribute the property amongst his sons, and he sometimes does so; but this is a distribution of his own property, and not a partition. The father can distribute the property as he pleases. But the absolute power of the father in this respect has only been recently established. It used to be thought that, if the father made a distribution, he must give to each of his sons an equal share. It is now settled that the father is absolute. Under the Mitacshara, the ownership being vested in the father and sons, there can be a partition between father and sons, and the sons can always insist that, if a partition is made, their rights shall be respected. Whether, under the Mitacshara law, the sons have the right to demand a partition in opposition to their father has been much

disputed. It is now generally considered that the sons have such a right.

In modern times if a partition takes place everything belonging to the family in common must be divided, even the idols. If there is only one idol, then each member of the family will be entitled to a "turn of worship," as it is called. It is, however, open to the members of the family to make any special arrangements either for retaining any portion of the property as joint, or as to the mode of carrying out of the partition, provided they can all agree to it. It is remarkable that in the Laws of Manu no such complete partition as can now be required is prescribed. A list of articles is given of considerable importance of which no partition could be claimed. In chap. ix. v. 219, it is said, "A dress, a vehicle, ornaments, cooked food, water, and female slaves, property destined for pious uses and sacrifices, and a pasture ground" are all declared to be indivisible. Land and the right of way to the family house were also at one time indivisible. These things, therefore, must have been used in common after partition had taken place, which looks as if the family were not entirely broken up; and it is possible that they inhabited several houses within the same enclosure, as is sometimes seen at the present day. It is not always easy to subdivide property amongst the sharers, especially where they are numerous; and cases occur where a better division could be made by selling the whole or a portion of the property, and dividing the proceeds. This could always be done with the consent of all the sharers; and now by Act IV. of 1893 of the Governor-General in council it can be done with the consent of a moiety in value of the sharers.

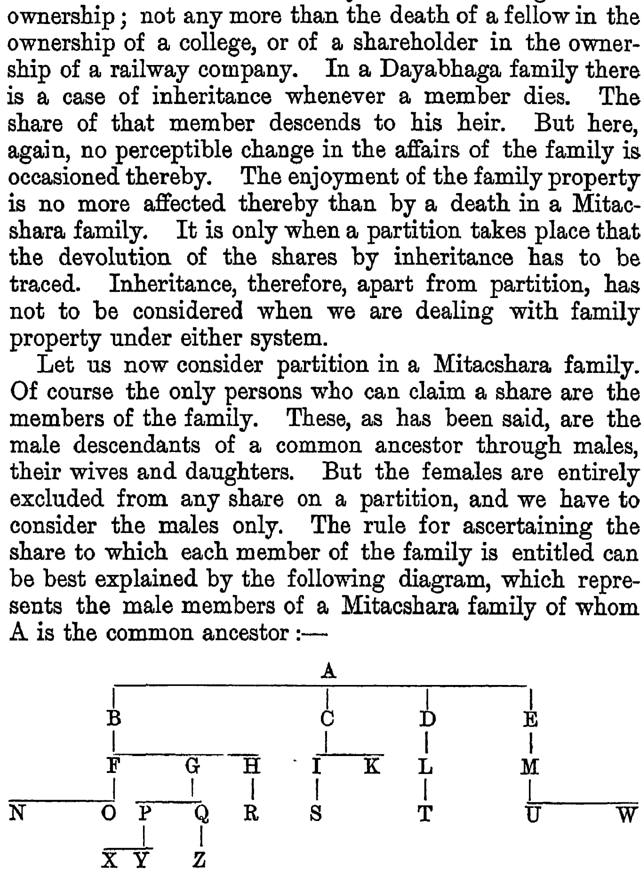
Rulers in India are apt to look upon their territories as private property, but there is no instance on record of the succession to the throne being considered as partible. On the contrary, in the families which now represent the small mediatized princes, the family property is frequently, by a special custom, considered to be impartible. The property descends to the eldest male, the younger members of the family getting allowances, generally in the form of temporary assignments of portions of the family property.

Persons who in ordinary circumstances would be entitled to claim a share in the family property may be disqualified from doing so by certain specified imperfections. According to the Laws of Manu (ix. 201), "Eunuchs, outcasts, persons born blind or deaf, madmen, and such as have lost the use of a limb," are excluded. According to Yajnavalkya, a person afflicted with an incurable disease is excluded. The leaning of the courts is against such exclusions. Outcasts have been relieved by Act XXI. of 1850, which expressly repeals the disqualification; and probably the only disease which would now exclude is the worst form of leprosy. Persons so excluded are not left unprovided for. Though excluded from partition, they can always claim a suitable maintenance.

Of course only the family property can be divided, and if any of the members make a claim on the ground of self-acquisition to exclude anything from partition, this claim must be considered; and if it is upheld, that portion of the property must be excluded from partition. These claims sometimes give rise to a good deal of litigation, and are not always easy to determine. It must be borne in mind, however, that self-acquired property becomes family property as soon as it has once descended. Thus if a man by a separate trade earns Rs.10,000, and dies leaving two sons and the son of a third son, these persons form a joint family, and the Rs.10,000 is family property. So also family property which has been partitioned remains family property still. Thus if A, a bachelor, gets on partition a piece of land and afterwards marries and has sons, under the Mitacshara law the father and sons form a joint family as soon as the sons are born, and to this family the land belongs.

Inheritance.—When we come to deal with the question of what shares are taken on partition, it is convenient to follow the example of the Hindu commentators, and to treat the subject of inheritance in conjunction with it. The relative importance of these two subjects has not always been perceived, particularly by the early English writers on Hindu law. Colebrooke, the learned and accomplished translator of the Mitacshara and the Dayabhaga, published the two treatises together in one volume which he called *The Law of Inheritance.* But these treatises, although they deal incidentally with inheritance, are both described by their authors as treatises on partition only; and this, no doubt, is because the subject of inheritance, apart from partition, is of comparatively small importance. Inheritance is the transfer of ownership which occurs at and in consequence of a death. It follows from this that in a Mitacshara joint family there is no inheritance. The death of a member of the family makes no change in the ownership; not any more than the death of a fellow in the ownership of a college, or of a shareholder in the ownership of a railway company. In a Dayabhaga family there is a case of inheritance whenever a member dies. The share of that member descends to his heir. But here, again, no perceptible change in the affairs of the family is occasioned thereby. The enjoyment of the family property is no more affected thereby than by a death in a Mitacshara family. It is only when a partition takes place that the devolution of the shares by inheritance has to be traced. Inheritance, therefore, apart from partition, has not to be considered when we are dealing with family property under either system.

Let us now consider partition in a Mitacshara family. Of course the only persons who can claim a share are the members of the family. These, as has been said, are the male descendants of a common ancestor through males, their wives and daughters. But the females are entirely excluded from any share on a partition, and we have to consider the males only. The rule for ascertaining the share to which each member of the family is entitled can be best explained by the following diagram, which represents the male members of a Mitacshara family of whom A is the common ancestor:—



The whole family may be considered as forming one group, which may conveniently be called the group A; and it is evident on inspection that the family may be subdivided into a number of smaller groups each similarly organized, each group consisting of a man and his own male descendants. Thus besides the group A we have the group B, consisting of B and his descendants; the group C, consisting of C and his descendants; and so on. A group may die out altogether, as if U and W were to die childless, E and M being already dead. The rule of partition proceeds upon the supposition—not an unnatural one—that a family, when it breaks up, separates always into groups, and that the shares are moulded accordingly. For example, suppose that when the partition is made the surviving members of the family are N, O, S, T, X, Y, Z;

then to find the shares we must go back to the common ancestor and reconstruct the pedigree. There were at first four groups, but at some time, it is immaterial when, by the death of E and all his descendants the groups have been reduced to three; hence the first step is to divide the property into three equal parts, assigning one to each group. The group B was originally represented by three smaller groups, but now by only two, the groups F and G, and to each of these we assign $\frac{1}{2}$ of $\frac{1}{3}$, or $\frac{1}{6}$. And, of the $\frac{1}{6}$ assigned to the group F, N will get $\frac{1}{12}$ and O will get $\frac{1}{12}$. The other $\frac{1}{6}$ is divided between the groups P and Q, each group getting $\frac{1}{12}$. Then in the group P, X and Y will each get $\frac{1}{24}$, while Z, as the sole representative of the group Q, will get $\frac{1}{12}$. It may be noted in passing that this principle of division survives in the succession *per stirpes* of which we find so many examples in other systems of law which had their origin in the patriarchal system. By a similar process we should find that S and T each got $\frac{1}{3}$ of the property, they being the sole representatives of the groups C and D respectively. For the sake of simplicity we have taken a case where no example occurs of a father and son being both alive at the time of partition. But suppose P to be alive in addition to the persons mentioned above; then the group P gets $\frac{1}{12}$, and that group consists of three persons, P, X, and Y. There is no precise rule as to how the partition was to be made in such a case in the older Hindu law, and it is rarely that a partition takes place between father and sons, but if there should be one it is always assumed that the shares are equal, *i.e.*, in the case under consideration each would take $\frac{1}{36}$.

Turning now to a Dayabhaga family, we find that the property is vested, not in the family as a whole, but in certain individual members of it—that is to say, in those male members of the family who have no ancestor alive. And inasmuch as the undivided share of each member is his own, it follows that at his death inheritance will operate, and it goes to his heirs. In order, therefore, to find what share each member takes on partition under the Dayabhaga, we must inquire into the history of the family and ascertain what share has become vested in each member of the family by the ordinary rules of inheritance. The rules of inheritance, as laid down in the Dayabhaga, are not very dissimilar to those which we find in other parts of the world. Everywhere we find that a man's property is taken by his nearest relatives, but there are differences in the way in which proximity is reckoned. Everywhere, also, there is a preference given to males and the relatives through males over females and the relatives through females, but there are differences in the extent to which this preference is carried. The relatives of a man through males are called his agnates; the relatives of a man through females are called his cognates. In the Hindu law as at present administered there is no primogeniture, and a decided preference of males over females, and of agnates over cognates. With regard to the question of proximity, the Dayabhaga lawyers deal with the matter in a very curious way. All Hindus, as is well known, offer some sort of sacrifice to their deceased relatives, and the person by whom the sacrifice is to be offered as well as the nature of the offering are very carefully prescribed. These sacrifices are said to confer a "spiritual benefit" upon the deceased, and this spiritual benefit is greater or less according to the nature of the offering and the person who offers it. Now the Dayabhaga lawyers say that the person whose offering confers the greatest spiritual benefit is entitled to succeed as heir. This being the theory, we must see what rules govern in India the offering of sacrifices to the dead.

The most important offering is that of the pinda, or rice cake, and the persons who are entitled to make this offering to the deceased are called his sapindas. The offering next in importance is that of the lepa, or fragments of the cake, the crumbs as we might call them, and the persons who make this offering are called sakulyas. The offering of least importance is the simple libation of water, and persons connected by this offering are called samonadacas. But who are sapindas, sakulyas, and samonadacas respectively, and of each class whose offering is most efficacious? Practically we shall find that this question is solved by rules of consanguinity not unlike those which we meet with elsewhere. First of all come the sons; their offering is most efficacious, so that they are the nearest heirs and all take equally. Then come the sons' sons; then the sons' sons' sons. Here we break off. The line of inheritance is not continued beyond the great-grandsons. There are other cases in which, as we shall see, there is a similar break when we get three degrees away from the propositus: nor is this peculiarity confined to the Hindu law. We find traces of a similar break in the Roman and in the Teutonic law. After the great-grandson comes the widow. It is difficult to establish her claim on the ground of spiritual benefit, and it rests upon authority rather than principle. The opinions of ancient writers on the subject are very conflicting. They are set forth at great length in the Dayabhaga, with a conclusion in favour of the widow. Probably the intrusion of the widow is connected with the fact that she could in early times by cohabitation with a brother, and in later times by adoption, procure an heir to her sonless husband. Next to the widow come the daughters, and then the daughters' sons. Their position, again, may be referred to the notion which prevailed in early times, that a Hindu who had no son of his own might take one of his daughters' sons and make him his own. Then comes the father, then the mother, then the brothers, then the brothers' sons, and then the brothers' sons' sons. The sisters are excluded, but their sons succeed after the brothers' sons' sons; then come the brothers' daughters' sons. Then, leaving this generation, we go a step backward, and proceed to exhaust the previous generation in precisely the same way. It is only necessary to enumerate these in their order:—father's father, father's mother, father's brothers, father's brothers' sons, father's brothers' sons' sons, father's sisters' sons, father's brothers' daughters' sons. Then going another step backwards we get father's father's father, father's father's mother, father's father's brothers, father's father's brothers' sons, father's father's sisters' sons, father's father's brothers' daughters' sons.

So far the line of succession is confined either strictly to male agnates, or to persons who may restore the broken line of male agnate relationship. But at this point, under the Dayabhaga, instead of exhausting the male agnates still further, as we might expect, we turn now to the cognates, *i.e.*, the relatives of the deceased through the mother. It is said that these are also in some way sapindas. They are generally called bandhus. There is some difficulty in finding out the order in which they succeed, and since it is rare that an heir has to be sought outside the father's family, the question has not been much discussed. The question would have to be decided by the religious doctrine of spiritual benefit, and it is not improbable that Hindus who are accustomed to keep up the sacrifices which confer the benefit would be able to say whose sacrifice was most efficacious. When all the sapindas both on the father's and mother's side are exhausted, we then go to the sakulyas, and practically these are found by continuing the enumeration of agnates upon the same principle as that already indicated through three generations lower and three generations higher. On failure of the sakulyas we should have to fall back upon the samonadacas, but probably all that can be said with

certainty is that the sakulyas and samonadacas between them exhaust entirely the male agnates of the deceased. Where there are several persons whose offerings are equally efficacious, *i.e.*, who stand in the same relationship to the deceased, they all take: the male descendants *per stirpes*, and the other relatives of the deceased *per capita*.

These, then, are the rules which govern the ascertainment of the shares of the members of a family on a partition. Neither in a Mitacshara family nor in a Dayabhaga family have they any effect so long as the family remains joint: it is partition, and partition only, which brings them into play, and it is to this event rather than death that Hindu lawyers attach the greatest importance. Nevertheless all property in India is not joint property. Under the Mitacshara as well as under the Dayabhaga separate property may be acquired, and then, of course, we have true inheritance, for which the law must provide. So far as regards the Dayabhaga, the rules which govern the inheritance of separate property are (as we should expect) precisely the same as those which govern the inheritance of a share, and it is therefore unnecessary to restate them. But it remains to lay down the rules of inheritance for separate property under the Mitacshara law. They are not based by Mitacshara writers upon any religious principle, as under the Dayabhaga, yet the result is not widely different. First come the sons, then the sons' sons, and then the sons' sons' sons. Then the widow, whose right has been disputed, but was long ago established; then the daughters, and then the daughters' sons. After these come the parents, and it is peculiar that of these the mother comes before the father, then the father's sons, and then the father's sons' sons. Then we go back to the preceding generation, and follow the same order—the father's mother, the father's father, the father's father's sons, the father's father's sons' sons. After this we go back another generation, and again follow the same order—father's father's mother, father's father's father, father's father's brother, father's father's brother's son. From this point the statements of Hindu lawyers as to the order of succession are very scanty and vague. One thing is certain, that under the Mitacshara law no cognates (relations through females) are admitted until all the agnates (relations through males) are exhausted.

Wills.—So far we have considered intestate succession only, and the power of testamentary disposition is unknown to the true Hindu law. It was introduced by the decisions of the British courts of justice. By a will is meant a declaration by a man of his wishes as to the disposition of his property after his death, taking no effect during his life. A will is therefore by its very nature revocable. The general question whether a Hindu could dispose of his property by will arose in Bengal when Hindus began to attempt to dispose of their property after their death according to the English method. At that time there was a doubt whether the father was so completely absolute that he could dispose of his property to the exclusion of his sons, even in his lifetime. As soon as it was settled that he could do so, it was assumed that he could also make a will. It seems never to have been asked why it was that up to this time no Hindu had ever made a will, or to question the radically false assumption that the power of alienation *inter vivos* and the power of testamentary alienation necessarily go together. A long series of decisions confirmed by the legislature has, however, established that a Hindu in modern times can dispose of any property of which he is the sole owner. In other words, a Hindu can dispose by will of his self-acquired property, and under the Dayabhaga a Hindu can dispose by will of his share in family property. But the courts which created the testamentary power have also limited it to disposition in favour of persons living at the time of the testator's decease, thus avoiding many of the fanciful dispositions of property to which testators in all countries are so prone. But, curiously enough, this restriction, salutary as it is, has also been based on the notion that a testamentary disposition is a gift from the testator to the object of his bounty.

Debts.—In almost all countries at an early stage of civilization some legal provision exists by which debtors can be compelled by their creditors to pay their debts, and by which, if they fail to do so, their property can be seized and applied to this purpose. But the extent to which this can be done varies very considerably. So long as the family system exists in its primitive vigour it acts as a protection to the family property against the extravagance of a single member, and we often find that even when the family system has almost, or completely disappeared, there is an unwillingness to deprive the future representatives of the family of their land and houses. Doubts, too, have arisen as to whether the same right which a creditor has against his living debtor can be exercised after the debtor's death against those who have succeeded to his property. In India these two considerations have been deeply affected by a principle enunciated by Hindu lawyers (traces of which we find in many Eastern countries), that a man who dies in debt suffers cruel tortures in a future state, and that it is the imperative duty of his own immediate dependants to deliver him from these tortures by discharging his liabilities. Whether this should be looked upon as a legal, or only as a purely religious duty, might be questionable: the courts have seized upon it as a basis for laying down in the broadest manner the just rule that those who take the benefit of succession must take the burdens also. The subject is one which has caused a great deal of litigation in India, and whilst some points have been clearly settled, others are still being slowly worked out. As the matter stands at present, it may be safely said that all separate property is liable for the debts of the owner, both in his lifetime and after his death in the hands of his heirs. The same may be said of the share in the family property of the member of a Dayabhaga family, of which share he is the owner. So also the family property under both the Dayabhaga and Mitacshara is liable, as a whole, for the debts incurred on behalf of the family as a whole. As regards the question of the liability of the family property for the separate debts of the members of a Mitacshara family, the courts have held that the sons must pay their father's debts. Of course illegality would be an answer to the claims of the creditors against the heirs, just as it would be an answer to the claim against the original debtor; but there is some authority for saying that a debt contracted for an immoral though not an illegal purpose would not be enforced against the heir. According to modern decisions also, if judgment and execution on a separate debt are obtained against the member of a Mitacshara family, the share which would fall to him upon a partition may by process of law be set apart and sold for the benefit of the creditor.

Maintenance.—The doctrine of what is called maintenance plays an important part in the Hindu law, and, as we shall see, it modifies considerably the rigour of the Hindu law in excluding from the succession females or persons suffering from mental or bodily infirmity. The right of maintenance under the Hindu law is the right which certain persons have to be maintained out of property which is not their own. The persons who in certain circumstances have this right are sons, widows, parents, and unmarried daughters and sisters. The claim of the widow arises at the death of her husband; of a child at the death of its parent, and so forth. The claim is not for a bare subsistence only, but to such a provision as is suitable to the claimant having

regard to his or her position in life. Of course the sons are generally heirs, and an heir can have no claim to maintenance; but a son excluded by any mental or bodily defect would have a right to maintenance. The girls are generally married in infancy, and after marriage they have no claim to maintenance from their own family. The most frequent claim is by the widow; and it is a very important one, because she can sometimes, through the assertion of this claim, put herself almost in the position of an heir. If a Hindu under the Dayabhaga dies leaving sons and a widow, the widow is entitled to maintenance, and whilst the family remains joint she can claim to be suitably maintained, in the family if she remains in her husband's house, or out of it if she goes elsewhere. But if a partition takes place she is entitled to have a share equal to that of the sons set aside for her use. She can even, if she thinks that the sons do not treat her properly, apply to the court to compel the sons to give her a separate share. This, of course, gives her a very strong position. Whether in a Mitacshara joint family the widow enjoying maintenance can in any case claim a share on partition is doubtful.

Women's Property.—In some respects, and as regards some kinds of property, the ownership of women under the Hindu law differs from that of men. These differences depend on the source from which the property is derived. If a woman has inherited property from a male, or as a gift by her husband, or has obtained it as a share on partition, she does not own it in the same way as a man would do; she obtains only a kind of restricted ownership. She has the full enjoyment and management of it, but she cannot sell it, or give it away, or dispose of it by will; and at her death it goes, not to her heirs, but to the heirs of the person from whom she obtained it; her ownership simply comes to an end. If she obtained it by inheritance from a male, it will go on her death to the heirs of that male; if as a share on partition, it will be divided amongst the other sharers; if as a gift from her husband, to the heirs of the husband. As regards property otherwise obtained she is in the same position as any other owner, but the rules of inheritance applicable to it are somewhat peculiar. It would be a mistake to look upon the restricted ownership of a woman as what the English lawyers call a life estate. There is no such thing as a remainder or reversion. The whole estate is vested in her. If we endeavoured to describe the position of affairs at her death in the technical language of the English law of real property, it would be more correct to say that there was a shifting use. The restriction on alienation is sometimes removed where there is a danger that the property might otherwise be lost, as, for example, when the property is likely to be sold for non-payment of Government revenue, in which case a portion may, if necessary, be sold by the woman so as to save the remainder. So also a woman who has no other means of maintaining herself, or of providing for the performance of religious duties which are incumbent upon her, may sell so much of the property as will produce the necessary funds. It would be difficult for a purchaser to know whether he would be safe in purchasing from a widow selling under necessity, and more difficult still to preserve evidence of the necessity in case the necessity were disputed. Of course the woman herself could not dispute the validity of the sales, but those who take after her might do so. Consequently it is not unusual to obtain the concurrence of the person who at the time of the purchase is entitled to succeed if the widow were dead, and it has been held that, if this person concurs in the sale, no one else can dispute it on the ground that it was unnecessary.

Husband and Wife.—The subject of marriage is dealt with at considerable length in the Laws of Manu, and it is clear that, as originally conceived, marriage under the Hindu law consisted in nothing more than the mere possession of the woman, however obtained, by the man with the intention of making her his wife. Eight kinds of marriage are enumerated, and to each kind is assigned a separate name. The first four kinds are merely different forms of gift of the girl by her father to the husband. The other four kinds are—obtaining possession of a girl by purchase, fraud, ravishment, or consent of the girl herself. But the simple gift of the girl by her father without any bargain or recompense was even then considered the most reputable form of marriage, and it is now the only one in common use amongst orthodox Hindus. The sale of the daughter was even in those early times stigmatized as disgraceful, but it was valid; and even now, if there were an actual transfer of the girl by the father, it is scarcely probable that the courts would inquire whether any inducement was given for the transfer. The transaction takes place entirely between the father of the girl and the future husband; the girl has nothing to do but to obey. If the girl has no father, then it will be the duty of her nearest male relatives to dispose of her in marriage. If, however, the girl is not married when she attains puberty (which is very rare) then she may choose a husband for herself. The father cannot dispose of his son in marriage as he can of his daughter, nor is anything said about his consent in the matter; though in the case of a very young boy there can be no doubt that the consent of one or both parents is obtained. The marriage of very young boys is very common, and is certainly valid.

The ceremonies which precede and accompany a marriage are very numerous. By far the most important is that which consists in the bridegroom taking the bride's hand and walking seven steps. Amongst Hindus generally the performance of this ceremony following upon a betrothal would be treated as conclusive evidence of a marriage, whilst the omission of it would, amongst orthodox Hindus, be almost conclusive that no marriage had yet taken place. But still any particular customs of the tribe or caste to which the parties belonged would always be considered, and it cannot be said that the completion or non-completion of this ceremony is universally conclusive as to the existence of a marriage. There may be communities of Hindus which require something more than this; there are certainly some which require something less, and others which require something altogether different. There are lower castes in some parts of India calling themselves Hindus in which the only ceremony accompanying a marriage is giving a feast to which the members of the two families are invited.

The marriage of Hindus is complete without consummation; and as girls are almost invariably married before the age of puberty, and sometimes long before, consummation is generally deferred, it may be, for several years. But all this time the parties are husband and wife, and if the husband dies the child becomes a widow. The condition of these child widows in India is certainly not an enviable one, for practically they can never hope to marry again. Whether the second marriage would be lawful was a disputed point in Hindu law, until an Act of the Indian Legislature (Act XV. of 1860) declared in favour of the opinion that the widow might remarry. But the social prejudice against remarriage is still very strong, and such a marriage rarely takes place. If the widow has inherited any property from her husband, she loses it by contracting a second marriage. There is no legal restraint upon the number of wives that a Hindu may marry, but polygamy is not practised so largely as is sometimes supposed.

Members of the three higher castes are forbidden to marry a woman of the same *gotra* as themselves. Literally a *gotra* means a cattle-yard, and the prohibition is con-

sidered to exclude marriage between all those who are descended from the same male ancestor through an uninterrupted line of males. This rule is said not to apply to Sudras. But there is another rule which applies to all Hindus, and prohibits the marriage of a man with a girl descended from his paternal or maternal ancestors within the sixth degree. The working out of the rule is a little peculiar, but the result is to give a rather wide rule of exclusion of both agnates and cognates. There is, however, this important exception to these rules of exclusion—that if a fit match cannot otherwise be procured, a man may marry a girl within the fifth degree on the father's side and the third on the mother's. Practically this reduces the limit of exclusion to that last stated, because no one but the parties themselves with whom the choice rested could say whether or no any other suitable wife was available to the husband.

A Hindu must also marry within his caste: a Brahmin must marry a Brahmin, a Rajput must marry a Rajput, and a Sudra must marry a Sudra. Whether there are any other representatives of the four original castes is very doubtful, and even the claim of the Rajputs to represent the military caste is disputed. Still the rule of prohibition is so far clear. But there are innumerable subdivisions of Hindus which are also called castes, and as a matter of fact these minor castes do not intermarry. How far such marriages would be lawful it is difficult to say. The matter is entirely one of custom. The ancient Hindu law furnishes no guide on the subject, because under the ancient law the intermarriages of persons of different castes, even the highest, though they were considered undesirable, were recognized as legal. Modern Hindus seem disposed to deny the validity of marriages between persons of different castes in either sense of the term.

Divorce, in the sense of a rupture of the marriage tie, is not known to the true Hindu law. But unchastity deprives a wife of all her rights except to a bare maintenance, and this without any legal proof. She cannot succeed her husband as his heir, and of course she cannot remarry. A little confusion has been caused by the fact that a Hindu husband sometimes goes through a private ceremony which is erroneously called a divorce. But this is only done in order more effectually to bar an unchaste wife from succeeding to his property. Some very low castes are, however, said to allow a husband to divorce his wife, and even to allow the divorced wife to marry again. The single case in which a Hindu marriage can be dissolved by a court of law is by a proceeding under Act XXI. of 1860, which was passed to meet the difficulties which arise when one of the parties to a Hindu marriage becomes a Christian. In this case, if the convert after deliberation during a prescribed time refuses to cohabit any longer with the other party, the court may declare the marriage tie to be dissolved, and a woman whose marriage has been thus dissolved is declared capable of marrying again.

Suttee.—An interesting chapter in the history of the modern development of Hindu law is that of the practice of what we call Suttee, though, properly speaking, the native term (*Sati*) denotes, not a practice, but a person, *i.e.*, a faithful wife. The practice in question is that of the widow burning herself with her husband when his body is burned after his death. This, according to Hindu ideas, is a laudable act of devotion on the part of the widow, and when Great Britain first began to administer the law in India it was not uncommon. The new-comers had not as yet taken upon themselves the responsibility of altering the law, but, of course, British officers did what they could to discourage the practice, and especially to prevent any pressure being put upon the widow to perform the sacrifice. They could also take advantage of any circumstance which would render the case an improper one for the performance of the sacrifice, as, for example, that compulsion had been put upon the widow, or that the burning did not take place with the body of the husband. But if the proceedings were according to Hindu notions regular, it was contrary to the principles on which the Governor-General then acted to interfere, and British officers had frequently to stand by, and, by not interfering, to give a sort of sanction to the sacrifice. When later the servants of the East India Company began to assume a more direct responsibility for the government of the country, many suggestions were made for legislative interference. But, acting on the salutary principle that it was unwise to interfere in any way with the religion of the people, the Government abstained from doing so. In the meantime a considerable body of opinion against the practice had grown up amongst Hindus themselves, and at length the Government thought it safe to interfere. By Regulation XVII. of 1829 widow-burning was declared to be a criminal offence. The measure produced no serious opposition. There was hardly a single prosecution under this Regulation; and from this time the practice of widow-burning has entirely disappeared from that part of India which is under British rule.

Father and Son.—There are certain peculiarities in the relation of father and son in India which have given rise to the suggestion that there is no relationship between sonship and marriage, and that the notion of sonship in India is founded entirely on that of ownership—ownership of the mother and a consequent ownership of the child. But the arguments by which this view is supported do not appear to be sufficient. The rights of a father over his son, and of a husband over his wife, are, it is true, so far like the rights of ownership that both are in the nature of rights *in rem*—that is, they are available against any person who infringes them; but it is contrary to established usage to speak of rights over a free person as rights of ownership, and no one is prepared to say that the wife or child are slaves of the father. There is no reason for abandoning in India the ordinary view, that sonship depends on marital cohabitation between the father and mother. There are undoubtedly in certain special and exceptional cases methods of acquiring sons otherwise than by marital cohabitation. But these contrivances can only be resorted to when there is no son by marriage, and the fiction which, as we shall see, is resorted to to conceal the true nature of these contrivances, would be entirely meaningless, as would most of the rules which regulate them, if sonship in general was based entirely on ownership. There were at one time more contrivances than there are now for supplying the want of male issue by marriage. At one time a son could be begotten for a man who was dead by cohabitation of his widow with a member of his family, or perhaps even with a stranger. This is generally looked upon as a survival of polyandry. But this practice, though alluded to in the Laws of Manu as still subsisting, is now entirely obsolete. So there was a custom at one time by which a father could appoint a daughter to raise up male issue for him. The head of the family could also, if he had no son born in wedlock, accept as his own any child born in his house whose mother was not known or not married. So he could accept as his own the son of his wife born before marriage, or the son of his concubine. In the three last cases he may have been, and probably was, himself the father. But none of these contrivances for procuring a son is now in use. The only contrivance now employed for procuring a son, in the absence of one born in wedlock, is by taking into the family the son of another man who is willing to part with him. This is called adoption. There are two kinds of adopted sons: one called dattaka, and the other kritrima. The former

is in use all over India; the latter only in Mithila. The following rules apply to the dattaka born of adoption:—A man can only adopt who is without issue capable of inheriting his property, of performing the funeral ceremonies for himself, and of making the necessary offerings to his ancestors. A woman cannot adopt. But by the authority of her husband, and acting on his behalf, she may select a son and receive him into the family. A man can adopt a son without his wife's assent; nevertheless, the son when adopted becomes the son of both parents.

Hindus consider it a grievous misfortune that the line of male descent should be broken. The due performance of the sacrificial offerings to the dead is thereby interrupted. Probably this explains the great latitude given in some parts of India to the widow to adopt a son on behalf of her husband in case he has died sonless. There is a text which says, "Nor let a woman give or accept a son unless with the assent of her lord." But the lawyers of Western India do not consider that any express permission to adopt is necessary, and take it for granted that she always has that permission. In Southern India, also, the widow may adopt without express permission, but the sapindas must give their sanction to make the adoption valid. Elsewhere the words have received their natural interpretation, namely, that the husband must in some way indicate his intention that his widow should have authority to adopt. The only person to whom an authority to adopt can be given is the wife or widow; and no widow can be compelled to exercise her power to adopt if she does not wish to do so. The father has absolute power to give away his son in adoption even without the consent of his wife. But her consent is generally asked and obtained before the son is given. After the father's death the widow may give a son in adoption. The rule which in former times rendered it necessary that the nearest male sapinda should be adopted is obsolete, and the adoption of a stranger is valid, although nearer relatives otherwise suitable are in existence. A man may adopt any child whose mother he could have married if she had been single; if he could not have done so, then he cannot adopt her child. The reason given in the text is that the adopted son must bear the resemblance of a son. This recalls the *dictum* of the Roman law—*adoptio naturam imitatur*. The adopted son and the adopting father must be of the same caste. The period fixed for adoption by the three higher castes is before the ceremony of upandyana, or investiture of the child with the thread which these castes always wear over the left shoulder. For Sudras, who have no thread, the period is prior to the marriage of the child. There has been much difference of opinion as to whether an only son can be given and received in adoption. It is now settled that the texts which discountenance this adoption do not constitute a prohibition which the law will enforce.

There is sometimes a difficulty in ascertaining whether or no an adoption has actually taken place. There must be a final giving and receiving of the child in adoption, and for Sudras nothing more is required. For the twice-born classes it is not finally settled whether any religious ceremony is actually necessary in order to render the adoption valid. But some religious ceremony in almost all cases accompanies the adoption, so that the absence of any such ceremony will always raise a suspicion that the adoption, though it may have been contemplated and some steps taken towards it, had not been finally completed. If an adoption were in itself invalid, no acquiescence and no lapse of time could make it valid—just as an invalid marriage could not be similarly validated. But acquiescence by the family would be strong evidence of the validity of an adoption, and the rules of limitation by barring any suit in which the question could be raised might render the adoption practically unassailable.

The kritrima adoption is altogether different; although the adopted son performs the ceremonies for his adopting father's family, and has a right to succeed, he is nevertheless not cut off from his own family. A person of any age may be adopted, and he must be old enough to be able to consent to the adoption, as without this consent it cannot take place. In this form a female can adopt, and no ceremonies are required.

Hindustan. See INDIA.

Hingham, a town of Plymouth county, Massachusetts, U.S.A., on Massachusetts Bay, contains the villages of Hingham Centre and South Hingham. Population (1890), 4564; (1900), 5059, of whom 969 were foreign-born.

Hiogo, or HYOGO, a Japanese town, situated in 34° 41′ N. and 135° 11′ E., in the province of Settsu, on the western shore of the bay of Osaka, adjoining the foreign settlement of Kobe. The growth of its prosperity has been very remarkable. Its population, including that of Kobe, was 135,639 in 1891, and 215,780 in 1898, and it thus stands fifth on the list of Japan's towns, being preceded only by Tôkyô, Osaka, Kyôtô, and Nagoya. From the following figures the development of Kobe's foreign trade may be seen:—

	Exports.	Imports.	Total.
1884	£1,180,490	£1,391,166	£2,571,656
1889	3,300,576	4,226,514	7,527,090
1894	3,679,764	7,113,813	10,793,577
1899	7,532,088	12,028,952	19,561,040

This increase—nearly eightfold in fifteen years—has not been confined to a few staples of commerce, but has been spread over almost the whole trade, especially silk and cotton fabrics, floor-mats, straw-plaits, matches, and cotton yarns. Kobe owes much of its prosperity to the fact that it serves largely as the shipping port of Osaka, which has become the chief manufacturing town in Japan. The citizens of Osaka, however, are engaged upon a large work of harbour construction, which, when completed, will probably divert a considerable part of the business now flowing to Kobe. But Kobe now ranks as the premier port of Japan. Its foreign community, however, has not grown in the same ratio, the figure at present—exclusive of Chinese—being only 1060 of all nationalities. Kobe is considered the brightest and healthiest of all the places assigned as foreign settlements in Japan, its pure dry air and granite subsoil constituting special advantages. It is in railway communication with all parts of the country, and wharves admit of steamers of large size loading and discharging cargo without the aid of lighters. The area originally appropriated for a foreign settlement soon proved too restricted, and foreigners received permission to lease lands and houses direct from Japanese owners beyond the treaty limits, a privilege which, together with that of building villas on the hills behind the town, ultimately involved some diplomatic complications. Kobe has a good shipbuilding yard, and

commodious docks will soon be constructed in its immediate neighbourhood.

Hiogo's original name was Bako. Its position near the entrance of the Inland Sea gave it some maritime importance from a very early period, but it did not become really prominent until the 12th century, when Kiyomori, chief of the Taira clan, transferred the capital from Kyôtô to Fukuhara, in Hiogo's immediate neighbourhood, and undertook various public works for improving the place. The change of capital was very brief, but Hiogo benefited permanently from the distinction thus conferred on it. (F. BY.)

Hippolytus.—Hippolytus, a presbyter of the Church in Rome, was exiled to Sardinia in A.D. 235 with Pontianus, bishop of Rome. Eusebius (*H.E.* vi. 20) represents him as a bishop without mentioning his see. Apollinaris of Laodicea calls him "the most holy bishop of Rome." In the 4th century he was regarded, probably rightly, as a martyr, and the Roman Church commemorates him on 13th August, on which day his remains were buried on the Via Tiburtina. He was a writer of the first importance. In 1551 a marble statue of Hippolytus, now in the Vatican, was discovered. The figure is clad as a philosopher; the chair contains a list in Greek of his writings, and reproduces part of the cycle for calculating Easter which he invented. This was the first attempt made by the Church to calculate the date of Easter by a cycle. The exegetical works of Hippolytus embraced all, or nearly all, the Bible. The only book that remains is that on Daniel (Greek and Slavonic). Hippolytus favours allegory, but is more sober than the Alexandrine writers. He wrote against heathens (πρὸς ἕλληνας καὶ πρὸς Πλάτωνα); also a treatise to the Empress Julia Mammæa; against heretics (σύνταγμα πρὸς ἁπάσας τὰς αἱρέσεις); against Marcion, &c.; also on the incarnation (περὶ οἰκονομίας), on the origin of evil, and περὶ Χριστοῦ καὶ ἀντιχρίστου: the last still remains.

Hippolytus was a preacher, and some genuine fragments which remain apparently were homilies. He has been the subject of modern controversy. In 1842 books iv.–x. of a work (κατὰ πασῶν αἱρεσέων ἔλεγχος) were discovered. They were found to fit with a work known as the φιλοσοφούμενα, wrongly attributed to Origen. The whole must have had two more books, ii. and iii., which are still missing. Book i. attacks Greek philosophers, iv. treats of astrology. Books v.–x. contain accounts of Christian heresies, partly based on earlier authorities; ix. tells of dissensions at Rome, and is of peculiar interest. It accuses Callistus, the bishop, of teaching Sabellianism. This fact has made some Roman Catholics desirous of proving that the book is not by Hippolytus, while some Protestants assert that Hippolytus was a rival Roman bishop or anti-pope. Some have even suggested that the Roman Church canonized him in spite of his schism, because his name gave occasion to continue the heathen festival of Virbius. The truth lies between these extreme theories. The φιλοσοφούμενα is shown by abundant internal evidence to be by Hippolytus. It refers to his σύνταγμα, and is connected with his works on Antichrist and Noetus. The question as to the episcopate of Hippolytus is obscure. It is hard to accept the story that he was bishop of Pontus. This apparently arose in the 7th century from the fact that Pontus contained a church having his name. The *Liberian Catalogue*, A.D. 354, probably quoting a 3rd-century notice, calls Hippolytus a presbyter. This document makes it certain that he died as a presbyter and in union with the Roman see. It is possible that he did for a time exercise episcopal functions, and that Pontianus and he were exiled while rivals. Pontianus resigned his bishopric 28th September 235, and perhaps Hippolytus resigned his claim at the same time, and so was reconciled with the Church. Apparently they were both alive when Anteros was consecrated pope, 21st November 235. They probably died in Sardinia, and their relics were brought to Rome under Pope Fabian. The history of Hippolytus has been obscured by the fact that Pope Damasus, followed by the poet Prudentius (*Peristeph.* 11, 17), speaks of a Hippolytus who had supported the schism of Novatus c. A.D. 251. Damasus was either writing of another Hippolytus, or confused the story. (For the Church Order bearing his name see CANONS OF HIPPOLYTUS.)

Hirado, an island belonging to Japan, $19\frac{1}{2}$ miles long and 6 miles wide, lying off the west coast of the province of Hizen, in 33° 15′ N. and 129° 25′ E. It is celebrated as the site of the original Dutch factory—often erroneously written Firando—and as the place where one of the finest blue-and-white porcelains of Japan (*Hirado-yaki*) was produced in the 17th and 18th centuries. The kilns are still active.

Hirosaki, a town in the province of Mitsinoku or Rikugo, North Nippon, Japan, 22 miles south-west of Aomori, on the route to Niigata. Population (1892), 28,000; (1898), 35,000. It is a very old place, formerly residence of a great daimio and capital of a vast principality, and still seat of a high court with jurisdiction over the surrounding provinces of Aomori and Akita. Like most places in North Nippon, it is built with continuous verandas extending from house to house, and affording a promenade completely sheltered from the snows of winter. Apples of fine flavour grow in the district, which also enjoys some reputation for its peculiar green lacquer-ware.

Hiroshima, a city and seaport of Japan, capital of the ken of like name in Central Nippon. In its general aspect it resembles Osaka, and is, next to that place and Hiogo, the most important commercial centre in the Inland Sea. Population (1892), 90,000; (1898), 122,000. The ken has an area of about 3000 square miles, with a population (1898) of nearly 1,500,000. Hiroshima is famous all over Japan owing to its association with the neighbouring islet of Itaku-Shima, "Island of Light," which is dedicated to the goddess Bentin and regarded as one of the three wonders of Japan. The chief temple dates from the year 587, and the island, which is inhabited largely by priests and their attendants, is annually visited by thousands of pilgrims. But the hallowed soil is never tilled, so that all provisions have to be brought from the surrounding districts.

Hirsch, Maurice de, BARON HIRSCH AUF GEREUTH, in the baronage of Bavaria (1831–1896), capitalist and philanthropist (German by birth, Austro-Hungarian by domicile), was born at Munich, 9th December 1831. His grandfather, the first Jewish land-owner in Bavaria, was ennobled with the *prädikat* "auf Gereuth" in 1818; his father, who was banker to the Bavarian king, was created a baron in 1869. The family for generations has occupied a prominent position in the German Jewish community. At the age of thirteen young Hirsch was sent to Brussels to school, but when seventeen years old he went into business. In 1855 he became associated with the banking house of Bischoffsheim & Goldschmidt, of Brussels, London, and Paris. He amassed a large fortune, which he increased by purchasing and working railway concessions in Austria, Turkey, and the Balkans, and by speculations in sugar and copper. While living in great splendour in Paris and London and on his estates in Hungary, he devoted much of his time to schemes for the relief of his Hebrew

co-religionists in lands where they were persecuted and oppressed. He took a deep interest in the educational work of the Alliance Israélite Universelle, and on two occasions presented the society with gifts of a million francs. For some years he regularly paid the deficits in the accounts of the Alliance, amounting to several thousand pounds a year. In 1889 he capitalized his donations and presented the society with securities producing an annual income of £16,000. On the occasion of the fortieth anniversary of the Emperor Francis Joseph's accession to the Austrian throne he gave £500,000 for the establishment of primary and technical schools in Galicia and the Bukowina. The greatest charitable enterprise on which he embarked was in connexion with the persecution of the Jews in Russia (see ANTI-SEMITISM). He gave £10,000 to the funds raised for the repatriation of the refugees in 1882, but, feeling that this was a very lame conclusion to the efforts made in Western Europe for the relief of the Russian Jews, he offered the Russian Government £2,000,000 for the endowment of a system of secular education to be established in the Jewish pale of settlement. The Russian Government was willing to accept the money, but declined to allow any foreigner to be concerned in its control or administration. Thereupon Baron de Hirsch resolved to devote the money to an emigration and colonization scheme which should afford the persecuted Jews opportunities of establishing themselves in agricultural colonies outside Russia. He founded the Jewish Colonization Association as an English society, with a capital of £2,000,000, and in 1892 he presented to it a further sum of £7,000,000. This enormous fund is now managed by delegates of certain Jewish societies, chiefly the Anglo-Jewish Association of London and the Alliance Israélite Universelle of Paris, among whom the shares in the association have been divided. The association, which is prohibited from working for profit, possesses large colonies in South America, Canada, and Asia Minor. Besides this great organization, Baron de Hirsch founded a benevolent trust in the United States for the benefit of Jewish immigrants, which he endowed with a sum of £493,000. His minor charities were on a princely scale, and during his residence in London he distributed over £100,000 among the local hospitals. It was in this manner that he disposed of the whole gross proceeds derived from his successes on the English turf, of which he was a lavish patron. He raced, as he said himself, "for the London hospitals," and in 1892, when his filly, La Flêche, won the Oaks, St Leger, and One Thousand Guineas, his donations from this source amounted to about £40,000. Baron de Hirsch married on 28th June 1855 Clara, daughter of Senator Bischoffsheim of Brussels, by whom he had a son and daughter, both of whom predeceased him. He died at Ogyalla, near Komorn, in Hungary, 21st April 1896. (L. W.)

Hirschberg, a town of Prussia, province of Silesia, 48 miles south-east of Görlitz by rail. The linen industry is now of minor importance, though it is still carried on, as are also the manufactures of yarn, paper, cement, cigars, cardboard, machinery and iron wares, and wood-carving. Here is the Riesengebirge Museum. Population (1885), 15,622; (1900), 17,867.

Hirson, a town in the arrondissement of Vervins, department of Aisne, France, 35 miles by rail north-east of Laon, on the Oise. It occupies an important strategic position close to the point of intersection of several railway lines, and not far from the Belgian frontier. For its defence there are a permanent fort and two batteries, near the railway junction. It is noted for basket-work, and there are manufactures of glass bottles, and iron and tin wares, and wool-spinning. The town had a communal charter in the 12th century. Population (1881), 4531; (1901), 7461.

Hissar, a town and district of British India, in the Delhi division of the Punjab. The town is situated on the Rajputana railway and Western Jumna canal, about 102 miles W.N.W. of Delhi. Population (1881), 14,138; (1891), 16,854. The municipal income in 1897–98 was Rs.30,043. It is now chiefly known for its cattle and horse fairs. The DISTRICT comprises an area of 5163 square miles, with a population in 1881 of 672,569, and in 1891 of 776,006, giving an average density of 150 per square mile. In 1901 the population was 781,575, showing practically no increase, whereas in the previous decade there had been an increase of 15 per cent. The land revenue and rates were Rs.10,23,852, the incidence of assessment being R.0–3–9 per acre; the cultivated area in 1896–97 was 380,671 acres, of which 180,204 were irrigated, almost entirely from government canals; the number of police was 681; the number of schools in 1896–97 was 141, with 4734 pupils, the proportion of boys at school to the male population of school-going age being 6·7 per cent., or little more than half the average for the province; the registered death-rate in 1897 was 45·31 per 1000. There are a printing-press, and nine factories for cleaning and pressing cotton. Hissar suffered severely in the recent famines. A section of the Rajputana railway, 147 miles in all, now traverses the district. There are 95 miles of metalled roads. The largest town is Bhiwani.

Hitchin, a market-town in the Hitchin parliamentary division of Hertfordshire, England, 32 miles north-north-west of London by rail. The grammar school (1632) has been reconstituted for boys and girls. George Chapman, the translator of Homer, was born here, as were also Sir Henry Bessemer in 1813 and Sir Henry Hawkins (Baron Brampton) in 1817. The most notable industry is the cultivation and distillation of lavender and peppermint. Area of urban district, 2624 acres. Population (1881), 8434; (1901), 10,072.

Hjelmar, a lake of Sweden, lies south-west from Lake Mälar, and 67 feet higher. Area of the lake, 185 square miles; of its drainage basin, 1625 square miles. Length of lake, nearly 40 miles; breadth, 2½ to 12 miles; depth, 59 feet. Its shores are flat, and subject to inundation. With the view of preventing this evil the level of the lake has been sunk 5¾ feet below its former mean level. This was effected by deepening the navigable channel through the lake (1878–84), by cleaning out the Hjelmar canal (1879–80) to 6¾ feet, and reconstructing the dam at the head of the Eskilstuna river and cleaning out that river (1880), and by draining the lake of Qvismare by means of a canal 12½ miles long, alongside the river Telje (one of the chief feeders of the lake), in 1879–87. By this means an area of 45,000 acres was won to cultivation.

Hkamti Lông (called Kantigyi by the Burmese, and Bor Hkampti by the peoples on the Assam side), a Shan state tributary to Burma, but at present beyond the administrative border. It lies between 27° and 28° N. and 97° and 98° E., and is bordered by the Mishmi country on the N., by the Patkoi range on the W., by the Hukawng valley on the S. and on the E., and indeed all round by various Chingpaw or Kachin communities. The country is little known. It was visited by T. T. Cooper, the Chinese traveller and Political Agent at Bhamo, where he was murdered; by the late General Woodthorpe and Colonel Macgregor in 1884, by Mr Errol Grey in the

following year, and by Prince Henry of Orleans in 1895. All of these, however, limited their explorations to the valley of the Mali-*hka*, the western branch of the Irrawaddy river. Hkamti has shrunk very much from its old size. It was no doubt the northernmost province of the Shan kingdom, founded at Mogaung by Sam Lông-hpa, the brother of the ruler of Kambawsa, when that empire had reached its greatest extension. The irruption of Kachins or Chingpaw from the north has now completely hemmed the state in, and the only hope of its Shan, or Tai, inhabitants of escape from extinction rests in support from the British Government. Lao Hkun, the present chief, has paid homage and tribute at Bhamo. Prince Henry of Orleans described it as "a splendid territory, fertile in soil and abundant in water, where tropical and temperate culture flourish side by side, and the inhabitants are protected on three fronts by mountains." According to him the Kiutze, the people of the hills between the Irrawaddy and the Salween, call it the kingdom of Moam. (J. G. SC)

Hoar.—The name of a father and two sons distinguished in American politics and jurisprudence. SAMUEL HOAR (1788–1856), like his two sons a graduate of Harvard, and trained to the practice of law, was for a generation a leading member of the Massachusetts bar, and served in the National Congress, 1835–37. In 1844, having been sent to Charleston, S.C., on a mission touching the treatment of free negroes in that port, he was forced by demonstrations of popular hostility to leave the city without completing his work. He married the daughter of Roger Sherman, the Connecticut statesman, and lived at Concord, Mass., where his two sons were born. The elder of these, EBENEZER ROCKWOOD HOAR (1816–1895), after attaining the highest judicial honours of his state, held for a short time (1869–70) the position of Attorney-General in the cabinet of President Grant, and was a member of Congress, 1873–75. The younger son, GEORGE FRISBIE HOAR (1826– ——), devoted himself to his profession at Worcester, with two short terms in the state legislature, till in 1869 he was elected to Congress by the Republicans. After two successive re-elections he declined to be again a candidate, and was thereupon, in 1877, chosen to represent Massachusetts in the Senate. Senator Hoar's legal learning gave him from the outset a high position among his colleagues. In 1891, upon the retirement of Senator Edmunds, he became Chairman of the Judiciary Committee, and this influential position he continued to hold whenever his party was in control. He has made a distinguished reputation in scholarship as well as in law and politics, and in 1895 he was President of the American Historical Association.

Hobart, the capital of Tasmania, in the south of the island, at the mouth of the river Derwent. It has been so called since the 1st of January 1881, when its name was changed from Hobart Town. It returns three members out of eighteen to the Legislative Council of the State, and six to the House of Assembly out of thirty-seven members. It has an incorporated area of 1270 acres, and its population in 1901 numbered approximately 34,604; namely, 25,076 in Hobart proper and 9528 in the remainder of the metropolitan area. The principal suburbs are Newton, Sandy Bay (Queensborough), Wellington, Glenorchy, Risdon, Bellerive, and Beltana. The total length of streets is 38 miles, and the annual value of ratable property £175,500; in 1899 the rates yielded a revenue of £33,360, and from other services the municipality obtained £10,242, making a total of £43,602. For public works the sum of £231,000 has been borrowed, against which there is a sinking fund, which at the beginning of 1899 amounted to £18,150. The water supply, which is under municipal control, is obtained from streams on Mount Wellington, and collected in reservoirs with a capacity of 120,000,000 gallons; the cost of constructing the works was £163,877. Gas is supplied by a private company, and the city is partly lighted with electricity, while electric tramways run through the main streets. It has four banks with branches and two public markets (one for fish), is well supplied with public baths, and has an efficient fire brigade, and is the seat of an Anglican bishopric and a Roman Catholic archbishopric; there are some thirty-five or forty churches of all denominations. Cemeteries now number only three, several old ones having been closed in recent years. The National Gallery contains some fine paintings, and in respect of parks and public spaces the city is exceptionally fortunate: the Queen's Domain, the principal park, has an area of 1000 acres; and there are also the Royal Society's Gardens, with an area of 25 acres; Franklin Square, a pleasant garden on the site of old Government House; Barrack Square, Prince's Square, which commands a beautiful view of the river and the lower part of the city; and Parliament House reserve, besides extensive recreation grounds at North Hobart, and a fine racecourse and a general recreation reserve at Risdon, close to the main line railway. The Theatre Royal is one of the best appointed theatres in the Commonwealth, and there are many halls where entertainments are sometimes given, and four clubs. The chief monuments in the city consist of statues of Sir John Franklin and Dr Crowther, the Meredith fountain, the Syme memorial, and, at the barracks, a column erected to the memory of the soldiers killed in the New Zealand war. Hobart Hospital is maintained by the Crown, and though hospitals generally and charitable institutions are not numerous, they are well equipped and sufficient for the wants of the city. At the Newton Charitable Institution the average daily number of inmates is about 470; and there are a boys' home, an industrial school for girls, and a Roman Catholic orphanage for girls. There are eight state schools, with 38 teachers and an average attendance of 1600; also a technical school and a large number of private schools, both primary and secondary. For the university, which was established in 1890, and is mainly supported by the state, the Government endowment in 1898 was £2900 out of a total revenue of £3436; it has three professors and four lecturers and 38 students, and up to the close of 1898 had conferred 129 degrees. During 1899, 265 vessels entered the port, with a tonnage of 383,354; in 1890 the number was 292 and the tonnage 273,494. Imports were valued at £682,498 in 1899, and exports at £846,342. During the fruit season Hobart is a place of call for the P. and O. Company and the Orient Company's boats, and a regular port of call for two other lines running between London and New Zealand. Several lines of steamers run to Sydney and Melbourne, and there is direct communication with New Zealand, whilst vessels are constantly plying all round the coast. As to its manufactures, there are three breweries, five tanneries, five sawmills, four jam factories, two steam flour-mills, two woollen mills, an important iron foundry, and many small engineering establishments. It is the centre of an important horticultural district, in which over 70,000 acres are under crops; of these about 9000 acres are devoted to orchards. The fruit export trade has reached very considerable dimensions; the production in 1899 was 364,000 bushels of apples, 33,738 bushels of pears, and 98,000 bushels of other kinds of fruit, and nearly all this was exported, chiefly to Sydney and London. (T. A. C.)

Hobart Pasha, Augustus Charles Hobart-Hampden (1822–1886), English naval captain and Turkish admiral, was born in Leicestershire on the 1st of April 1822, being the third son of the 6th Earl of Buckinghamshire. In 1835 he entered the Royal Navy and served as a midshipman on the coast of Brazil in the suppression of the slave trade, displaying much gallantry in the operations. In 1855 he took part, as captain of the *Driver*, in the Baltic Expedition, and was actively engaged at Bomarsund and Abo. In 1862 he retired from the navy with the rank of post-captain; but his love of adventure led him, on the outbreak of the American Civil War, to participate in that struggle in the character of blockade-runner. In command of a swift cruiser he succeeded in eluding no less than eighteen times the ironclad blockade squadron of the North, conveying war material to Charleston and returning with a cargo of cotton. In 1867 Hobart entered the Turkish service, and was immediately nominated to the command of that fleet, with the rank of "Bahrie Limassi" (rear-admiral). In this capacity he performed splendid service in helping to suppress the insurrection in Crete, and was rewarded by the Sultan with the title of Pasha (1869). In 1874 Hobart, whose name had, on representations made by Greece, been removed from the British Navy List, was reinstated; his restoration did not, however, last long, for on the outbreak of the Russo-Turkish war he again entered Turkish service. In command of the Turkish squadron he completely dominated the Black Sea, blockading the ports of South Russia and the mouths of the Danube, and paralysing the action of the Russian fleet. On the conclusion of peace Hobart still remained in the Turkish service, and in 1881 was appointed Mushir, or marshal, being the first Christian to hold that high office. His achievements as a blockade-runner, his blockade of Crete, and his handling of the Turkish fleet against the torpedo-lined coasts of Russia, showed him to be a daring, resourceful, and skilful commander, worthy to be ranked among the illustrious names of British naval heroes. He died at Milan, 19th June 1886.

Hobart, Garret Augustus (1844–1899), Vice-President of the United States 1897–99, was born at Long Branch, N.J., in 1844. Having graduated from Rutgers College, he practised law at Paterson, N.J., and rose to prominence in the state. In politics he was long conspicuous in the state Republican organization. He served several terms in both the lower and the upper house of the legislature, and was presiding officer of each. Though he never aspired to national office, he accepted the nomination as Vice-President in 1896, on the ticket with President McKinley, and was elected. At Washington his force of character won for him more influence than is generally exerted by a Vice-President; but he was seized with a fatal illness, and was taken to his home at Paterson, N.J., where he died 21st November 1899.

Hoboken, a city of Hudson county, New Jersey, U.S.A., in 40° 44′ N. and 74° 01′ W., on the west bank of the Hudson river, just north of Jersey City, with which it is connected by lines of steam and street cars, and opposite New York, of which it is a suburb, and with which it is connected by ferries. It has a large ocean commerce, the docks of several steamship companies being situated here. It is also an important manufacturing centre; in 1890 it contained 289 establishments, with a capital of $3,948,782, employing 3347 hands, and with a product valued at $7,151,391. It contains the Stevens Institute of Technology, which was founded in 1871, and which has a high rank among technical schools. In 1899 it had 30 professors and instructors and 361 students. Its property was valued at $823,000, and its income was $57,000. The total assessed valuation of real and personal property in 1900, on a basis of about 70 and 50 per cent. of the full value respectively, was $27,790,930; the net debt was $1,292,113, and the rate of taxation was $24·20 per $1000. Population (1880), 30,999; (1890), 43,648; (1900), 59,364, of whom 21,380 were foreign-born and only 101 were negroes. The death-rate in 1890 was 25·9; in 1900 it was 21·1.

Hoboken, a town of Belgium, in the province and 4 miles south of the town of Antwerp. It contains numerous villas of Antwerp merchants, and has a large shipbuilding yard. Population, 9523.

Höchst, a town of Prussia, province of Hesse-Nassau, on the Main, 6 miles by rail west of Frankfort-on-Main. It is a busy industrial town, with large dyeworks and manufacture of snuff, tobacco, waxcloth, gelatine, furniture, &c. It has a fine 9th-century basilica in the church of St Justinus. All that survives of the castle of the Electors of Mainz from the destruction in 1634 is a single fine tower. There is a statue of Bismarck (1899). Population (1885), 6517; (1900), 14,123.

Höchstädt, a town of Bavaria, Germany, district of Swabia, on the left bank of the Danube, 34 miles north-east of Ulm by rail. It has been a place of battles. Here Frederick of Staufen, vicegerent of the empire for Henry IV., was disastrously defeated by Henry's rival in 1081; in 1703 the Imperialists were routed by Marshal Villars in command of the French; and in 1704 Marlborough and Prince Eugene defeated the French and Bavarians commanded by the Elector of Bavaria and Marshal Tallard. This last event is better known in English history and English poetry (Southey) as the battle of Blenheim, more correctly Blindheim. Population (1900), 2246.

Hodgson, Brian Houghton (1800–1894), English ethnologist and naturalist, was born at Lower Beech, Prestbury, Cheshire, on 1st February 1800. His father was a country gentleman, his mother being a sister of Bishop Porteus. In 1816 he obtained an East Indian writership. After passing through the usual course at Haileybury, he went out to India in 1819, and after a brief service at Kumaon was in 1822 appointed assistant to the resident at Katmandu, the capital of Nepal. In 1822 he obtained an under-secretaryship in the Indian Foreign Office, which seemed to open the most brilliant prospects, but his health failed in the climate of Calcutta, and in 1824 he returned to Nepal, to which the whole of his life, whether in or out of India, may be said to have been thenceforth given. He devoted himself in an especial manner to the collection of Sanskrit MSS. relating to Buddhism, and hardly less so to the natural history and antiquities of the country, and by 1839 had contributed eighty-nine papers to the *Transactions* of the Asiatic Society of Bengal. His investigations of the ethnology of the aboriginal tribes were especially important. In 1833 he became Resident, and passed many stormy years in conflict with the cruel and faithless Court to which he was accredited. He succeeded, nevertheless, in concluding a satisfactory treaty in 1839; but in 1842 his policy, which involved an imperious attitude towards the native government, was upset by the interference of Lord Ellenborough, but just arrived in India, and, not unnaturally, anxious to avoid trouble in Nepal during the conflict in Afghanistan. Hodgson took upon himself to disobey his instructions, a breach of discipline justified to his own mind by his superior knowledge of the situation, but which the Governor-General could hardly be expected to

overlook. He was, nevertheless, continued in office for a time, but was recalled in 1843, and resigned the service. In 1845 he returned to India and settled at Darjiling, where he devoted himself entirely to his favourite pursuits. In 1858 he returned to England, and lived successively in Cheshire and Gloucestershire, occupied with his studies to the last. He died at his seat at Alderley Grange in the Cotswold Hills, 23rd May 1894. No man has done so much to throw light on Buddhism as it exists in Nepal, and his collections of Sanskrit manuscripts, presented to the East India Office, and of natural history, presented to the British Museum, are unique as gatherings from a single country. He wrote altogether 184 philological and ethnological and 127 scientific papers, as well as some valuable pamphlets on native education, in which he took great interest. His principal work, *Illustrations of the Literature and Religion of Buddhists* (1841), was republished with the most important of his other writings in 1872–80. His life was written by Sir W. W. Hunter in 1896. (R. G.)

Hof, a town of Bavaria, Germany, district Upper Franconia, on the river Saale, 103 miles south by west of Leipzig by the railway to Ratisbon. The seat of various flourishing industries, notably the manufacture of woollen and cotton goods, dye-works, calico printing, chemicals, machinery, iron and copper wares, breweries, and limestone quarries. Population (1885), 22,257; (1900), 32,782.

Hofmann, August Wilhelm von (1818–1892), German chemist, was born at Giessen on 8th April 1818. Not intending originally to devote himself to physical science, he first took up the study of law and philology at Göttingen, and the general culture he thus gained stood him in good stead when he subsequently began to study chemistry in Liebig's laboratory. When, in 1845, a school of practical chemistry was started in London, under the style of the Royal College of Chemistry, Hofmann, largely through the influence of the Prince Consort, was appointed its first director. It was with some natural hesitation that he, then a *privat-docent* at Bonn, accepted the position, which may well have seemed rather a precarious one; but the difficulty was removed by his appointment as extraordinary professor at Bonn, with leave of absence for two years, so that he could resume his career in Germany if his English one proved unsatisfactory. Fortunately the college was more or less successful, owing largely to his enthusiasm and energy, and many of the men who were trained there subsequently made their mark in chemical history. But in 1864 he returned to Bonn, and in the succeeding year he was selected to succeed Mitscherlich as professor of chemistry and director of the laboratory in Berlin University. In leaving England, of which he used to speak as his adopted country, Hofmann was probably influenced by a combination of causes. The public support extended to the college of chemistry had been dwindling for some years, and before he left it had ceased to have an independent existence and had been absorbed into the School of Mines. This event he must have looked upon as a curtailment of its possibilities of usefulness. But, in addition, there is only too much reason to suppose that he was disappointed at the general apathy with which his science was regarded in England. No man ever realized more fully than he how entirely dependent on the advance of scientific knowledge is the continuation of a country's material prosperity, and no single chemist ever exercised a greater or more direct influence upon industrial development. In England, however, people cared for none of these things, and were blind to the commercial potentialities of scientific research. The college to which Hofmann devoted nearly twenty of the best years of his life was starved; the coal-tar industry, which was really brought into existence by his work and that of his pupils under his direction at that college, and which with a little intelligent forethought might have been retained in England, was allowed to slip into the hands of Germany, where it is now worth millions of pounds annually; and Hofmann himself was compelled to return to his native land to find due appreciation as perhaps the foremost chemist of his time. The rest of his life was spent in Berlin, and there he died on 5th May 1892. That city possesses a permanent memorial to his name in Hofmann House, the home of the German Chemical Society (of which he was the founder), which was formally opened in 1900, appropriately enough with an account of the latest triumph of German chemical enterprise, the industrial manufacture of synthetical indigo. Hofmann's work covered a wide range of organic chemistry, though with inorganic bodies he did but little. His first research, carried out in Liebig's laboratory at Giessen, was on coal-tar, and his investigation of the organic bases in coal-gas naphtha established the nature of aniline. This substance he used to refer to as his first love, and it was a love to which he remained faithful throughout his life. His perception of the analogy between it and ammonia led to his famous work on the amines and ammonium compounds and the allied phosphorus derivatives, while his researches on the colouring matters obtained from it, beginning with rosaniline in 1862, only ended with quinoline red in 1887. But in addition to these and numberless other investigations for which he was responsible—his last communication from the Berlin University laboratory bears the number 888—the influence he exercised through his pupils must also be taken into account. As a teacher, besides the power of accurately gauging the character and capabilities of those who studied under him, he had the faculty of infecting them with his own enthusiasm, and thus of stimulating them to put forward their best efforts. In the lecture-room he laid great stress on the importance of experimental demonstrations, paying particular attention to their selection and arrangement, though, since he himself was a somewhat clumsy manipulator, their actual exhibition was generally entrusted to his assistants. He was the possessor of a clear and graceful, if somewhat florid, style, which showed to special advantage in the obituary notices or encomiums he wrote of such men as Liebig, or Dumas, or Wöhler. He also excelled as a speaker, particularly at gatherings of an international character, for in addition to his native German he could speak English, French, and Italian with fluency. (H. M. R.)

Hofmeister, Wilhelm Friedrich Benedict (1824–1877), German botanist, was born at Leipzig, 18th May 1824. He came of a family engaged in trade, and after being educated at the realschule of Leipzig he entered business as a music dealer; much of his botanical work was done while he was so employed, till in 1863 he was nominated, without intermediate academic steps, to the chair in Heidelberg; thence he was transferred in 1872 to Tübingen, in succession to von Mohl. His first work was on distribution of the Coniferæ in the Himalaya, but his attention was very soon devoted to studying the sexuality and origin of the embryo of Phanerogams; his contributions on this subject extended from 1847 till 1860, and they finally settled the question of the origin of the embryo from an ovum, as against the prevalent pollen-tube theory of Schleiden: he showed that the pollen-tube does not itself produce the

embryo, but only stimulates the ovum already present in the ovule. He soon turned his attention to the embryology of Bryophytes and Pteridophytes, and gave continuous accounts of the germination of the spores and fertilization in Pilularia, Salvinia, Selaginella. Some of the main facts of the life of Ferns and Mosses were already known; these, together with his own wider observations, were worked into that great general pronouncement published in 1851 under the title, *Vergleichende Untersuchungen der Keimung, Entfaltung und Fruchtbildung höherer Kryptogamen und der Samenbildung der Coniferen.* This work will always stand in the first rank of botanical books. It antedated the *Origin of Species* by eight years, but contained facts and comparisons which could only become intelligible on some theory of descent. The plan of life-story common to them all, involving two alternating generations, was demonstrated for Liverworts, Mosses, Ferns, Equiseta, Rhizocarps, Lycopodiaceæ, and even Gymnosperms, with a completeness and certainty which must still surprise those who know the botanical literature of his time. The conclusions of Hofmeister remain in their broad outlines unshaken, but rather strengthened by later-acquired details. In the light of the theory of descent the common plan of life-history in plants apparently so diverse as those named acquires a special significance; but it is one of the remarkable features of this great work that the writer himself does not theorize: with an unerring insight he points out his comparisons and states his homologies, but does not indulge in explanatory surmises. It is the typical work of an heroic age of plant-morphology. From 1857 till 1862 Hofmeister wrote occasionally on physiological subjects, such as the ascent of sap, and curvatures of growing parts, but it was in morphology that he found his natural sphere. In 1861, in conjunction with other botanists, a plan was drawn up of a handbook of physiological botany, of which Hofmeister was to be editor. Though the original scheme was never completed, the editor himself contributed two notable parts, *Die Lehre von der Pflanzenzelle* (1867) and *Allgemeine Morphologie der Gewächse* (1868). The former gives an excellent summary of the structure and relations of the vegetable cell as then known, but it did not greatly modify current views. The latter was notable for its refutation of the spiral theory of leaf arrangement in plants, founded by Schimper and Braun. Hofmeister transferred the discussion from the mere study of mature form to the observation of the development of the parts, and substituted for the "spiral tendency" a mechanical theory based upon the observed fact that new branchings appear over the widest gaps which exist between next older branchings of like nature. With this important work Hofmeister's period of active production closes; he fell into ill-health, and retired from his academic duties some time before his death at Lindenau, near Leipzig, on the 12th of January 1877. (F. O. B.)

Hofmeyr, Jan Hendrik (1845–——), South African politician, was born at Cape Town on 4th July 1845. He was educated at the South African College, and at an early age entered the profession of journalism. He was editor of the *Zuid Afrikaan* till its incorporation with *Ons Land*, and of the *Zuid Afrikaansche Tidjschrift.* By birth, education, and sympathies a typical Dutch Afrikander, he became, almost from his first entrance into the Cape Parliament in 1879, the real leader of the Dutch party. Yet he only held office for six months—as minister without portfolio in the Scanlen ministry from May to November 1881. He held no subsequent official post in the colony, though he shared with Sir Thomas Upington and Sir Charles Mills the honour of representing the Cape at the Intercolonial Conference of 1887. Here he supported the proposal for entrusting the defence of Simonstown to Cape Colony, leaving only the armament to be provided by the Imperial Government, opposed trans-oceanic penny postage, and moved a resolution in favour of an Imperial customs union. At the Colonial Conference of 1894 at Ottawa he was again one of the Cape representatives. But his chief importance as a public man is derived from his connexion with the Afrikander Bond. (See CAPE COLONY.) His control over this organization enabled him for many years, while free from the responsibilities of office, to make and unmake ministers at his will, and earned for him the name of "Cabinet-maker of South Africa." Although officially the term "Afrikander" has been explained by Mr Hofmeyr to include white men of whatever race, yet in practice the influence of the Bond was always exerted in favour of the Dutch language, or rather the local dialect of Dutch known as "the Taal," and its power was drawn from the Dutch districts of Cape Colony. The sympathies of the Bond were thus always strongly with the Transvaal, as the chief centre of Dutch influence in South Africa; and Mr Hofmeyr's position might in many respects be compared with that of Parnell at the head of the Irish Nationalist party in Great Britain. In the Bechuanaland difficulty of 1884 Mr Hofmeyr threw all the influence of the Bond into the scale in favour of the Transvaal. But in the course of the next few years he began to drift away from President Kruger. He resented the reckless disregard of Cape interests involved in Kruger's fiscal policy; he feared that the Transvaal, after its sudden leap into prosperity upon the gold discoveries of 1886, might overshadow all other Dutch influences in South Africa; above all he was convinced, as he showed by his action at the London Conference, that the protection of the British navy was indispensable to South Africa, and he set his face against Kruger's intrigues with Germany, and his avowed intention of acquiring an outlet to the sea in order to get into touch with foreign Powers. In 1890 he joined forces with Mr Cecil Rhodes, who became premier of Cape Colony with the support of the Bond. Mr Hofmeyr's influence was a powerful factor in the conclusion of the Swaziland Convention of 1890, as well as in stopping the "trek" to Banyailand in 1891—a notable reversal of the policy he had pursued seven years before. But the reactionary elements in the Bond grew alarmed at Mr Rhodes's Imperialism, and in 1895 Mr Hofmeyr resigned his seat in Parliament and the presidency of the Bond. Then came the Jameson Raid, and in its wake there rolled over South Africa a wave of Dutch and anti-British feeling such as had not been known since the days of Majuba. Once more Mr Hofmeyr became president of the Bond. By an alteration of the Provincial Constitution, all power in the Cape branch of the Bond was vested in the hands of a vigilance committee of three, of whom Mr Hofmeyr and his brother were two. As the recognized leader of the Cape Dutch, he protested against such abuses as the dynamite monopoly in the Transvaal, and urged Kruger even at the eleventh hour to grant reasonable concessions rather than plunge into a war that would involve Cape Afrikanderdom and the Transvaal in a common ruin. In July 1899 he journeyed with Mr Herholdt to Pretoria, and vainly supported the proposal of a satisfactory franchise law, combined with a limited representation of the Uitlanders in the Volksraad, and in September urged the Transvaal to accede to the proposed joint inquiry. During the negotiations of 1899, and after the outbreak of war, the official organ of the Bond,

Ons Land, was conspicuous for its anti-British attitude, and its violence forced Lord Roberts to suppress it in the Cape Colony district under martial law. Mr Hofmeyr never associated himself publicly with the opinions expressed by *Ons Land*, but neither did he repudiate them. The tide of race sympathy among his Dutch supporters made his position one of great difficulty, and shortly after the outbreak of war he withdrew to Europe, and refused to act as a delegate, with Messrs Merriman and Sauer, to England in 1901.

Hogarth, William (1697–1764). To the account of Hogarth given in the ninth edition of this Encyclopædia the following additions require to be made in view of more recent contributions to our knowledge concerning him. The precise place of Hogarth's birth was Bartholomew Close, where, two years later, his sister Mary was born. He had a second sister, Ann, who was born in 1701. Richard Hogarth, his father, died in May 1718. By the earlier commentators "A Harlot's Progress" was dated 1733–34 (vol. xii. p. 48). It has now been ascertained that Hogarth must have begun to engrave this series—a task which he had at first intended to leave to others—shortly after the conclusion of the last picture in 1731. From an advertisement in the *Country Journal; or, the Craftsman*, 29th January 1732, the pictures were then being engraved; and from later announcements it seems clear that they were delivered to the subscribers early in the following April, on the 21st of which month an unauthorized prose description of them was published. From the MSS. of George Vertue in the British Museum (Add. MSS. 23069–98), it appears that, during the progress of the plates, Hogarth was domiciled with his father-in-law, Sir James Thornhill, in the Middle Piazza, Covent Garden (the "second house eastward from James Street"); and the "Five Days' Peregrination" (May 27–31) must have followed "A Harlot's Progress" instead of preceding it. What Hogarth did to decorate Vauxhall beyond the picture of Henry VIII. and Anne Boleyn is not clear, as the "Four Times of the Day" are said to have been copies by Hayman; but Jonathan Tyers certainly presented him with a gold pass ticket *In perpetuam Beneficii memoriam*, which was lately in the Forman Collection, and now belongs to Mr Fairfax Murray. Mr Warwick Wroth (*Numismatic Chronicle*, vol. xviii.) doubts if Hogarth designed this himself, as generally stated, but he probably did design some of the silver passes to Vauxhall which are figured in Wilkinson's *Londina Illustrata*. Of late years several valuable pictures by Hogarth have passed into the possession of the National Gallery. In July 1895 the Duke of Westminster presented "The Gates of Calais"; and the Trustees have also purchased "Lavinia Fenton as Polly Peachum" (1884), "The Shrimp Girl" (1884), Hogarth's "Six Servants" (1892), and "Mrs Salter," Hogarth's sister Ann (1898). To the National Portrait Gallery was added in 1892, by the gift of the Earl of Carlisle, "The House of Commons examining Bambridge" (vol. xii. p. 47). The Print Room at the British Museum also acquired in July 1896, from Mr E. Cheney, a very interesting set of sixteen designs for the series called "Industry and Idleness," the majority of which formerly belonged to Horace Walpole. Hogarth's house at Chiswick (vol. xii. p. 50), of which he was admitted copyholder in September 1749, and which he left at his death to his widow, is still in existence. In December 1901 it was sold by its owner, Mr Alfred Dawson of Chiswick, to Lieutenant-Colonel Shipway for £1500. A life of Hogarth, together with a copious bibliography of books, pamphlets, &c., relating to the painter and his work, and detailed catalogues of his prints and paintings, was issued in 1891 by the present writer. In 1897 it was followed by a new and greatly enlarged edition. It should be added that "Sloane Museum" (vol. xii. p. 50) is a misprint for Soane Museum; and that the National Portrait Gallery is now at St Martin's Place. (A. D.)

Hohenelbe (Bohemian or Czech, *Vrchlabí*), chief town of a government district, Bohemia, Austria, at the source of the Elbe, 14 miles W.N.W. of Trantenau. Its industries now include iron-foundries and the manufacture of machinery, pottery, brewing and milling, and marble works, in addition to its staple trade in textiles. It is the starting-point for excursions in the Riesengebirge. Population, mostly German and Roman Catholic (1900), 6597. The adjoining village of Ober-Hohenelbe has a population of 2420, with bleaching works and linen and jute manufactories.

Hohenems, or HOHENEMBS, a market-place in the government district of Dornbirn, Vorarlberg, Austria, situated on the right-hand slope of the upper Rheinthal and on the Feldkirch–Bregenz section of the Austrian State Railway. Population (1900), 5662. The chief industries are cotton spinning, weaving, printing, and dyeing, manufactures of yarn, ribbons, and machine embroidery, and there is considerable trade in timber. It is inhabited by the only Jewish community in Vorarlberg, which numbers 118 souls, and has a synagogue. The village has two châteaus, that of Neu-Hohenems and one belonging to Count Waldburg-Zeil. The Hohenembs family became extinct in the male line in the latter half of the 18th century. The title is included in the full list of those borne by the Austrian Emperor, who occasionally uses it when travelling incognito. The late Empress Elizabeth of Austria usually travelled as Countess of Hohenembs.

Hohenheim, a village of Würtemberg, Germany, 5 miles south of Stuttgart by rail. It is the seat of the most important agricultural college in Germany. The college was founded in 1818, and established in a royal pleasure castle, built in 1782 by Duke Karl Eugen. To it have since been added a forestry college (1820), a farming school for peasants' sons, a horticultural and a viticultural school, a technological institute, an institute for testing agricultural seeds (1877), an institute for testing agricultural machinery (1883), a model steam dairy and butter and cheese factory (1883), a fisheries institute and fish-breeding station (1886), a fowl-breeding establishment (1890), a bacteriological institute, a chemical laboratory, botanical gardens of 15 acres, a herbarium of 27,000 plants, an agricultural estate of 800 acres, an orchard, a vineyard, experimental fields, a forest of 6500 acres, experimental stations for testing various processes, a library, physical laboratories, mineralogical, geological, veterinary, and zoological museums, a museum of agricultural implements and various collections of objects connected with farming, a meteorological station; also, in connexion with the technological institute there are a distillery, a brewery, a vinegar factory, and a sugar factory. The college was raised to the position of a high school in 1865, and now ranks with the technical high schools, and consequently has university status. The course is for three years, and there are 27 professors and teachers, and usually rather more than 100 students, including several foreigners. Population, about 280.

See British Diplomatic and Consular Reports, Miscellaneous Series, No. 452, *Agriculture in Germany* (1898), p. 14, &c.; and No. 566, *Würtemberg Schools* (1901), p. 32, &c.

Hohenlimburg, a town of Prussia, province of Westphalia, 30 miles by rail S.E. of Dortmund. It is the seat of various iron and metal industries. A castle overlooks the town. Population (1900), 8111.

Hohenlohe-Schillingsfürst, Chlodwig Karl Victor, Prince of (1819–1901), German statesman, was born 31st March 1819. He belonged to a Catholic branch of one of the most widely extended of German princely families, which until 1806 ruled over considerable dominions in Swabia, and still possesses all the social privileges secured to the mediatized princes. He studied at the universities of Heidelberg, Göttingen, and Bonn, and entered the Prussian civil service. In the year 1845, large estates in Prussia having been left to the family by the Landgraf of Hesse-Rothenburg, a connexion of his mother's, Prince Victor, the eldest brother, took them as his share, and received the title of duke of Ratibor from the king of Prussia; Prince Chlodwig received the Bavarian estates, and became a hereditary member of the Bavarian Upper House, while he also had the title prince of Ratibor. In 1849 he held for a few months a diplomatic post in England, but for the next fifteen years he took little part in public affairs. His attachment to Prussia threw him into opposition to the prevalent opinion in Bavaria. With all his family he belonged to the party of Liberal Catholics; the duke of Ratibor was one of the few Roman Catholics who supported Bismarck in his struggle with the Church, and a younger brother, the Cardinal Hohenlohe, was the leader of the opposition to the Ultramontanes in the Vatican Council. In 1872 Bismarck proposed to appoint Cardinal Hohenlohe Prussian envoy at the Vatican, but the Pope refused to accept a cardinal in this position. After the crisis of 1866, when it was desirable to form a ministry in Bavaria which would carry out the new alliance with Prussia, the king entrusted Hohenlohe with the task. He was minister-president for three years; he took a leading part in arranging the customs parliament, which was the first step towards a closer union of North and South Germany, and he carried out a reorganization of the Bavarian army on the Prussian system; he also brought about a military union of the southern states. During these years he was the most important German statesman next to Bismarck, for he made possible the union of Bavaria with Prussia in 1870. He also issued a celebrated despatch in which he invited the Catholic Powers to interfere at the Vatican Council and prevent the declaration of Papal infallibility; but the greater Powers were too much occupied to venture on so serious a step, and Bavaria was too weak to act alone. His policy was, however, bitterly attacked by the "patriotic" party, who accused him of betraying the independence of Bavaria; they were supported by the Ultramontanes, and when Hohenlohe brought in a Bill for the reorganization of the schools, by which the influence of the Church would be diminished, it was lost. His followers were twice defeated in the elections of 1869, and, notwithstanding the support of the king, he had to resign. He supported and helped to carry the treaty of 1870 with North Germany, and was elected a member of the German Reichstag. In 1873 Bismarck chose him to succeed Count Arnim as ambassador in Paris. In 1879, on the death of Bülow, he acted for some time as secretary of state for foreign affairs, and was the third German representative at the Congress of Berlin. In 1885 he was chosen to succeed Manteuffel as governor of Elsass-Lothringen. Here he had to carry out the strict measures which became necessary in 1887–88, but he succeeded in laying the foundation of a Nationalist party. In 1894, notwithstanding his advanced years, he was appointed Prussian minister-president and chancellor of the empire in succession to Caprivi. (For the events connected with his administration see Germany.) He took a less active part in public business than either of his predecessors; his appearances in the Prussian and German parliaments were rare, and great independence was allowed to the secretaries of state. On more than one occasion the want of a strong controlling force was felt, especially in the management of Prussian affairs. He resigned in August 1900, and died 6th July 1901.

Prince Hohenlohe married in 1851 Marie, princess of Sayn-Wittgenstein-Berleburg, by whom he had several children. On the death of Prince Peter of Sayn-Wittgenstein in 1887 the princess succeeded to his very extensive possessions in Russia. A recent law, however, forbade foreigners to hold land in Russia, and all the influence of the prince was unable to procure an exemption.

Other members of the family of Hohenlohe who have attained distinction in recent years are Prince Adolf von Hohenlohe Ingelfingen (1797–1873), a son of the general who commanded at Jena; he was minister-president of Prussia for a few months in 1862. His son, Prince Kraft von Hohenlohe (1827–1892), Prussian general, was the author of a number of important military works, most of which have been translated into English. A cousin of his was Prince Friedrich Wilhelm von Hohenlohe, duke of Ujest (1816–1897), one of the wealthiest of the Prussian nobility. These all belong to the Protestant branch, as do the family of Hohenlohe-Langenburg, to which belongs Prince Hermann von Hohenlohe, general in the Prussian army, founder and president of the German Colonial Society, and after 1894 governor of Elsass-Lothringen, in which post he succeeded Prince Chlodwig von Hohenlohe. His son, the Hereditary Prince of Hohenlohe-Langenburg, married a daughter of Alfred, Duke of Saxe-Coburg-Gotha, and became regent of the principality during the minority of the present duke. The family of Hohenlohe-Langenburg hold also the title of Count Gleichen. Through the mother of the present prince, a princess from Leiningen, they are closely connected with the English Royal family.

See Rust. *Reichskanzler Fürst Hohenlohe und seine Brüder.* Dusseldorf, 1897. (J. W. He.)

Hohenmauth (Czech, *Vysoké Mýto*), chief town of a government district in Bohemia, Austria. It has now a communal Czech gymnasium, and among its new industries are the manufacture of musical instruments, artificial manure, and pottery. Population, almost wholly Czech (1900), 9473, including a garrison of 1452 men.

Hohenzollern, a bailiwick of the kingdom of Prussia, on the Danube, and almost entirely surrounded by Würtemberg and Baden, with an area of 441 square miles, and population (1900) of 66,780, of whom 95 per cent. are Roman Catholics. Agriculture and a little mining, fruit-growing, and manufacture of iron-ware and cottons are the principal industries.

Hokkaido, the Japanese name for the northern division of the empire (*Hoku* = north, *kai* = sea, and *do* = road), including Yezo, the Kuriles, and their adjacent islets.

Holbeach, a market-town and railway station in the Spalding parliamentary division of Lincolnshire, England, 17 miles south of Boston. All Saints' Church (14th century), with a spire 180 feet high, has been restored; there are Congregational, Baptist, Wesleyan, and other chapels; the grammar school, founded in 1669, has an endowment of about £220 a year, and occupies a building erected in 1877. Other public buildings are the assembly rooms and a market house. Roman and Saxon remains have been found. Area of parish (an urban district), 21,469 acres. Population (1881), 5190; (1901), 4752.

Holden, Hubert Ashton (1822–1896), English scholar, was born, of an old Staffordshire family, in 1822, and educated at King Edward's School, Birmingham, and Trinity College, Cambridge. He was Bell University Scholar (1842) and senior classic (1845), besides being a junior optime in the mathematical tripos, and was elected a fellow of his college, where he remained for some time as tutor. In 1848 he was ordained. From

1853 to 1858 he was vice-principal of Cheltenham College, and from 1858 to 1883 headmaster of Queen Elizabeth's School, Ipswich. He took his Cambridge LL.D. in 1863, and in 1893 was given by Dublin the degree of Litt.D. Dr Holden was one of the finest classical scholars of his time; in 1848 he produced an edition of Aristophanes, and in subsequent years edited various works of Plutarch, Xenophon, Thucydides, and Cicero. His chief title to remembrance, however, rests on his *Foliorum Silvula* (1852), a collection of English poetry and prose for translation into Greek and Latin; *Folia Silvulæ* (the translations), which ran through many editions; and *Foliorum Centuriæ*. In English schools these books became household words, and were indissolubly connected with the writing of Latin and Greek verse. He died in London, 1st December 1896.

Holden, Sir Isaac (1807–1897), English inventor and manufacturer, was the son of Isaac Holden, a miner of Cumberland, and was born at Hurlet, a village between Paisley and Glasgow, 7th May 1807. His early life was passed in very straitened circumstances, but his father spared no pains to give him as much elementary education as possible. Necessity, however, compelled the boy to seek employment, and he obtained work for two years as weaver's draw-boy, and afterwards in a cotton mill. Meanwhile his education was continued at the night schools, and from time to time, as funds allowed, he was taken from work and sent to the grammar school, to which he at last went regularly for a year or two until he was fifteen, when his father removed to Paisley and apprenticed him to an uncle, a shawl-weaver there. This proved too much for his strength, and he became assistant teacher to Mr John Kennedy until January 1828, when he was appointed mathematical teacher in the Queen's Square Academy, Leeds. At the end of six months he was transferred to Lingard's Grammar School, near Huddersfield, and shortly afterwards became classical master at Castle Street Academy, Reading. It was here that in the course of chemical experiments he invented a lucifer match by adopting sulphur as the medium between the explosive material and the wood, but he refused to patent the invention. In 1830 his health again failed, and he returned to Scotland, where a Glasgow friend set up a school for him. After six months, however, he was recommended for the post of bookkeeper to Messrs Townend Brothers, of Cullingworth, where his interest in machinery soon led to his transfer from the counting-house to the mill. Here he pursued a series of experiments in wool-combing, which ultimately led to the foundation of the firm of Lister & Holden, whose wool-combing business was also established successfully in France. Owing to Holden's devotion to the improvement of his machinery, and his special success in the "square motion" principle, the business grew rapidly, and several branches were established. In January 1859 Mr Lister retired, and the firm of Isaac Holden & Sons was established, which became the largest wool-combing business in the world, employing upwards of 4000 workpeople. In 1865 Holden's medical advisers insisted on complete change of occupation, and he entered upon a parliamentary career in the Liberal interest, and was elected for Knaresborough in July of that year. In 1868 he resigned his seat, and unsuccessfully contested the Eastern Division of the West Riding, the Northern Division in 1872, and again the Eastern Division in 1874. But on the death of Lord Frederick Cavendish in 1882 he was elected for the Northern Division, and returned in 1885 for Keighley. He was created a baronet in 1893, and continued to represent Keighley until his death in 1897.

Holguin, a town in the interior of Santiago province, Cuba, 65 miles N.N.W. of Santiago de Cuba. It was noted as a revolutionary centre. It is connected by rail with Gibara. Population (1899), 6045.

Holl, Frank (1845–1888), English painter, was born in London on 4th July 1845, and was educated chiefly at University College School. He was a grandson of William Holl, an engraver of note, and the son of Francis Holl, A.R.A., another engraver, whose profession he originally intended to follow. Entering the Royal Academy schools as a probationer in painting in 1860, he rapidly progressed, winning silver and gold medals, and making his début as an exhibitor in 1864 with "A Portrait," and "Turned out of Church," a subject picture. "A Fern Gatherer," 1865; "The Ordeal," 1866; "Convalescent" (the somewhat grim pathos of which attracted much attention), and "Faces in the Fire," 1867, succeeded. Holl gained the travelling studentship in 1868; the successful work was characteristic of the young painter's mood, being "The Lord gave, and the Lord hath taken away." His insatiable zeal for work of all kinds began early to undermine the artist's health, but his position was assured by the studentship picture, which created a sort of *furore*, although, as with most of his works, the blackness of its coloration, probably due to his training as an engraver, was even more decidedly against it than the sadness of its theme. Otherwise, this painting exhibited nearly all the best technical qualities to which he ever attained, except high finish and clearness, and a very sincere vein of pathos. Holl was much below Millais in portraiture, and far inferior in all the higher ways of design; in technical resources, relatively speaking, he was but scantily provided. The range of his studies and the manner of his painting were narrower than those of Josef Israëls, with whom, except as a portrait-painter, he may better be compared than with Millais. In 1870 he painted "Better is a Dinner of Herbs where Love is, than a Stalled Ox and Hatred therewith"; "No Tidings from the Sea," a scene in a fisherman's cottage, in 1871—a story told with breath-catching pathos and power; "I am the Resurrection and the Life," 1872; "Leaving Home," 1873, "Deserted," 1874, both of which had great success; "Her First-born," girls carrying a baby to the grave, 1876; and "Going Home," 1877. In 1877 he painted the two pictures shown in our Plate, "Hush" and "Hushed." "Newgate, Committed for Trial," a very sad and telling piece, first attested the breaking down of the painter's health in 1878. In this year he was elected A.R.A., and exhibited "The Gifts of the Fairies," "The Daughter of the House," "Absconded," and a very fine portrait of Samuel Cousins, the mezzotint engraver. This last canvas is a masterpiece, and deserved the success which attended the print engraved from it. Holl was overwhelmed with commissions, which he would not decline. The consequences of this strain upon a constitution which was never strong were more or less, though unequally, manifest in "Ordered to the Front," a soldier's departure, 1880; "Home Again," its sequel, in 1883 (after which he was made R.A.). In 1886 he produced a portrait of Millais as his diploma work, but his health rapidly declined, and he died at Hampstead, 31st July 1888. Holl's better portraits, being of men of rare importance, attest the commanding position he occupied in the branch of art he so unflinchingly followed. They include likenesses of Lord Roberts, painted for Queen Victoria, 1882; the Prince of Wales, Lord Dufferin, the Duke of Cleveland, 1885; Lord Overstone, Mr Bright, Mr Gladstone, Mr Chamberlain, Sir J. Tenniel, Earl Spencer, Viscount Cranbrook, and a score of other important subjects. (F. G. S.)

HOLLAND.

Geography and Statistics.

HOLLAND, as the Kingdom of the Netherlands is generally termed in English, is a maritime country of North-West Europe, bounded on the E. by Germany, on the S. by Belgium, and on the W. and N. by the North Sea. Since 1880 the dykes and dunes have been considerably strengthened by the erection of new breakwaters, walls, &c., at several places, more particularly at West Kappel, near Domburg (Walcheren), along the coast of Delftland and Scheveningen (since the storms of 1894–95), at Petten and the Hondsbossche in North Holland (1884–88), around the shores of Ameland and Vlieland (1880–97), islands which protect the entrance to the Zuyder Zee, and along the coast of the northern provinces. Taking the division of the country into *Lowlands*, lying below the Amsterdam zero (or mean high-water level in front of that city), and *Highlands* (lying above that level), the former may be considered to occupy 38 per cent. of the surface and the latter 62 per cent. A more detailed classification, however, distinguishes seven zones, running roughly from west to east:—

Zone.	1	2	3	4	5	6	7
Mean Altitude between (metres)	−2·5 and 0	0 and 1	1 and 5	5 and 10	10 and 25	25 and 50	50 and 10
Percentage of Total Area	25	13	12	12	24	12	2

The figures indicate the mean height of the zones; the height of the hills is greater: near Vaals (Limburg) the extreme altitude of 1057 feet is reached.

Climate.—The following table supplies data respecting the climate on an average of fifty years:—

Month.	Mean Monthly Temperature.	Mean Monthly Barometric Height.	Average Rainfall.	Average Evaporation.
	Fahr.	Inches	Inches.	Inches.
January	34·64°	29·93	1·93	0·46
February	37·22°	29·45	1·75	1·23
March	40·73°	29·90	1·75	2·12
April	48·85°	29·90	1·49	3·12
May	56·48°	29·92	1·94	5·91
June	62·40°	29·95	2·16	6·88
July	65·10°	29·94	2·97	6·53
August	64·40°	29·93	3·19	3·45
September	59·25°	29·94	2·60	2·07
October	50·65°	29·88	2·87	1·20
November	41·32°	29·89	2·34	0·73
December	36·70°	29·93	2·41	0·59

The mean annual temperature is 49·8° Fahr.; the maximum, 93·9° Fahr.; the minimum, −5·8° Fahr. The mean annual barometric height is 29·93 inches; the mean annual moisture, 81 per cent.; the mean annual rainfall, 27·99 inches. The mean annual number of days with rain is 204, with snow 19, and with thunderstorms 18. The increased rainfall from July to December (the summer and autumn rains), and the increased evaporation in spring and summer (5·2 inches more than the rainfall), are of importance as regards "poldering" and draining operations. The prevalence of south-west winds during nine months of the year and of north-west during three (April–June) has a strong influence on the temperature and rainfall, tides, river mouths and outlets, and also, geologically, on dunes and sand drifts, and on fens and the accumulation of clay on the coast.

Area and Population.—In 1889 the area showed a slight diminution as compared with that of 1877, being calculated to be 12,558 square miles. Including the Zuyder Zee and sand islands (2027 square miles) and the Dutch portion of the Dollart (23 square miles), the total area was returned as 14,613 square miles. About 38 square miles have been reclaimed since 1877 from the Y, Groningen (the Dollart), Zeeland, and the Legmeer.

The following table shows the area and population of the provinces severally:—

Province.	Area in Square Miles.	Population 1889.	Population 1900.	Density Per Square Mile in 1900.
North Brabant	1,980	509,628	553,842	280
Gelderland	1,965	512,202	566,549	288
South Holland	1,166	949,641	1,144,448	981
North Holland	1,070	829,489	968,131	905
Zeeland	690	199,234	216,295	313
Utrecht	534	221,007	251,034	470
Friesland	1,282	335,558	340,262	265
Overyssel	1,291	295,445	333,338	258
Groningen	790	272,786	299,602	379
Drenthe	1,030	130,704	148,544	144
Limburg	850	255,721	281,934	332
Total	12,648	4,511,415	5,104,137 [1]	404

[1] This total includes 158 persons assigned to no province.

The divergence between the density in North and South Holland and that in Drenthe has become more marked than ever. On 1st January 1900 there were twenty-two cities with a population of over 25,000, as compared with only nine thirty years earlier, since when the populations of even the largest had almost, and in some cases more than, doubled. The eight largest were, Amsterdam (510,850), Rotterdam (318,500), The Hague (206,020), Utrecht (102,080), Groningen (66,530), Haarlem (64,080), Arnhem (56,810), Leyden (53,650). The following table gives particulars of the births (living), deaths, and marriages for the whole country in 1889, 1899, and 1900:—

Year.	Births.		Deaths.		Marriages.	
	Number.	Per Thousand.	Number.	Per Thousand.	Number.	Per Thousand.
1889	150,529	33·2	91,135	20·1	31,494	7·0
1899	163,289	32·0	87,319	17·1	37,990	7·4
1900	162,611	31·8	92,043	18·3	39,419	7·7

The illegitimate births in 1900 numbered 4247, as compared with an annual average of 4264 for the years 1879–84, and an annual average of 4529 for the period 1879–1900. There is but little emigration; the number of emigrants annually in 1887–91 was 5271, but this fell in 1896–1900 to 1255.

Changes in Government.—Since 1878 the number of members in the First Chamber has been increased from 39 to 50, South Holland sending 10, North Holland 9, North Brabant and Gelderland each 6, Friesland 4, Overyssel, Limburg, and Groningen each 3, Zeeland, Utrecht, and Drenthe each 2. According to the fundamental law of 1887, they are chosen by the provincial states not only from amongst those who bear the greatest burden of direct taxation in each province, but also from amongst great functionaries and persons of high rank. The members of the Second Chamber number 100. The franchise has been extended until the number of electors—only 3·02 per cent. of the population in 1880—formed 11·19 per cent. in 1900.

Religion.—At the census of 1900 the population was classified thus as regards religion:—

Provinces.	Dutch Reformed.	Other Protestants.	Roman Catholics.	Jansenists.	Jews.	Other Creeds & Unknown
N. Brabant	50,626	13,362	486,847	12	2,108	887
Gelderland	314,414	38,951	201,939	365	5,160	5,720
S. Holland	683,664	140,533	277,442	1,994	17,406	23,409
N. Holland	444,334	142,705	266,356	4,589	61,960	48,187
Zeeland	127,147	28,959	54,456	12	426	5,295
Utrecht	134,647	27,637	83,069	1,737	1,435	2,509
Friesland	204,902	83,653	24,831	7	1,545	25,324
Overyssel	196,497	37,768	89,845	6	4,507	4,715
Groningen	199,070	60,218	19,624	24	6,038	14,628
Drenthe	112,193	22,600	9,242	7	2,292	2,210
Limburg	3,459	712	276,452	1	1,111	199
Total	2,470,953	597,098	1,790,103	8,754	103,988	143,083

The state contributes annually about £164,000 towards the funds of the various denominations.

Education.—The following tables show the progress of education:—

Primary Education.

Year.	Number of Schools.	Number of Teachers.	Pupils. Boys.	Pupils. Girls.	Illiterate per 10,000	Infant Pupils.	Educational Expenditure	Illiterate Conscripts.
							£	%
1875	3,817	11,975	55,485	67,912	1,626	73,018	514,480	12·3
1898	4,544	23,532	379,622	351,066	845	115,985	1,349,473	2·8

Secondary Education.

Year.	Burgher Schools.[1]			High Burgher Schools					
				Boys.			Girls.		
	Schools.	Pupils.	Teachers.	Schools.	Pupils.	Teachers.	Schools.	Pupils.	Teachers.
1875	78	8,087	521	51	3,847	581	9	691	101
1898	126	17,217	1,226	63	8,143	839	12	1,586	174

[1] For drawing and industrial art; technical schools for workmen.

In 1900 the elementary schools numbered 4569, the teachers 24,222, and the pupils (boys and girls) 539,810; the burgher schools 137, the teachers 1225, and the pupils 18,478; the high burgher schools 75, the teachers 1024, and the pupils (boys and girls) 10,299. Of the total number of children of school age (six to twelve years) about 8½ per cent. receive no education. Besides the universities mentioned below, there is the "free (Reformed) university" of Amsterdam, attended in 1900 by 126 students. In 1900 the Polytechnic School numbered 714 pupils, the National School of Agriculture nearly 200, and eleven schools of navigation 1564, with 71 instructors. In 1899 the state spent £883,330 upon education, and the communes an additional £1,003,583. The following universities provide for—

Higher Education.

Year.	Leyden. Prof.	Leyden. Stud	Utrecht. Prof.	Utrecht. Stud.	Groningen. Prof.	Groningen. Stud.	Amsterdam Prof.	Amsterdam Stud.	Amsterdam, Free. Prof.	Amsterdam, Free. Stud.
1898–99	50	792	39	775	38	397	50	929	6	128

Gymnasia (including Latin or Grammar Schools).

Year.	Number.	Teachers.	Pupils.
1899–1900 . .	29	426	2259

The expenditure of the universities and gymnasia amounted in 1877 to £88,141, in 1898 to £253,715. Since 1870 there have been instituted schools of cookery and domestic economy, a technical school for engineers at Amsterdam, schools of commerce and administration, schools for instruction in horticulture and dairy work, for the training of teachers (for primary schools), for the blind, deaf, and mute, for drawing and industrial art, and for music, dramatic study, painting, and architecture. The number of museums and collections of antiquities, engravings, &c., has also been increased.

Crime and Pauperism.—There are a high court, 5 courts of justice, 23 district tribunals, 106 cantonal courts. Trial by jury is unknown. In 1900, 96,869 persons altogether were convicted by the cantonal courts, and 13,236 males and 1254 females at the district tribunals. The number of inmates in prison at the end of 1898 was 2123 males and 156 females; in houses of detention 712 males and 58 females. There are three state workhouses for drunkards, beggars, and vagabonds; the number of inmates at the end of 1898 was 3759. Children under sixteen years of age placed in the three state reformatories in 1898 numbered 593 boys and 98 girls. The relief of the poor is largely effected by religious societies and organized private charities. The state does not interfere except when private charity fails; in that case the pauper must be supported by the commune. The number of poor relieved during 1898 was 235,295, or 4·69 per cent. of the total population.

Finance.—The following statement shows the revenue and expenditure of the kingdom for 1889 and 1900–1:—

Revenue. Source.	1889	1901.	Expenditure. Object.	1889.	1901.
	£	£		£	£
Excise	3,678,075	4,042,500	National Debt	2,727,591	2,906,214

Railways	...	361,512	Unanticipated Expenses . . .	1,745	4,166
Total[1]	9,475,337	11,394,220	Total[2]	10,393,579	12,896,289

[1] Including the ordinary revenue (the Indian contributions ceased in 1878), balances from previous budgets, proceeds of sale of domains, &c., which are not specified in details.

[2] Including, besides the ordinary budget, the outlays in payment of annuities, in funding and discharging debt, in railway extension, &c.

The total debt in 1901 amounted to £96,561,287, the annual interest amounting to nearly 3 millions sterling. During the years 1850–1900, £26,034,422 has been devoted to the redemption of the public debt. The total wealth of the kingdom is estimated at 888 millions sterling.

The following table gives a statement of the provincial and communal finances:—

	Revenue. 1889.	Revenue. 1900.		Expenditure. 1889.	Expenditure. 1900.
	£	£		£	£
Provincial	722,583	445,333	Provincial .	740,333	445,333
Communal	6,132,000	9,311,666	Communal	5,683,800	8,503,250

Defence.—The standing army in 1898–99 formed a force of 69,316, as compared with 60,000 in 1878. Of these 3253 were raised by voluntary enlistment, 11,773 were conscripts in arms, 54,290 conscripts not in arms. Personal service has been compulsory since 1898. There are 43,690 in the militia "train-bands" or *schuttery*. The strength of the navy in 1899 consisted of 741 officers and 10,601 men, including marine infantry. The fleet was composed on 1st January 1900 of 32 armour-plated and 68 non-armour-plated ships, with 39 ships for general purposes. The guns numbered about 550. Both seamen and marines are recruited by enlistment.

Agriculture.—The following statement shows the uses to which the land was put in 1899:—Arable land, 26 per cent.; pasture and hay fields, 34 per cent.; market and flower gardens and orchards, 1·65 per cent.; woodland, 6·8 per cent.; waste lands (in 1876, 23 per cent.), 18 per cent.; the remainder is occupied by water, roads, dykes, buildings, &c. Both the diluvium (sandy soil) and the alluvium (marine and fluvial clay) are adapted for agriculture and grazing; the orchards, &c., are principally on the *geest* or higher grounds on the border of the dunes, or skirting the sand and clay strata. The area of waste land has been lessened by the plantation of woods, cultivation of heaths and fens, improved irrigation and

means of communication, and a reduction in the number of sheep. The following table shows the areas under cultivation in grain and other marketable crops in 1899 :—

Crops.	Acres	Mean Production per Acre.	
		1876–80.	1898–99.
		Bushels.	Bushels.
Wheat . . .	178,153	23·61	28·3
Rye . . .	530,383	19·38	24·4
Potatoes . .	385,727	124·78	204·9
Oats . . .	317,993	41·23	50·0
Buckwheat . .	71,989	17·37	17·1
Beans and Pease .	147,416	22·84	28·9
Barley . . .	88,117	30·21	41·0
Rape seed . .	11,815	23·51	28·9
		Cwt.	Cwt.
Beetroot . .	115,233	183·8	254·0
Flax . . .	19,840	3·40	4·8

In addition, over 470,000 acres are annually planted with fodder plants. Notwithstanding the improved production per acre and the progress of agricultural science (promoted by the Government, societies, schools, settlements, winter courses, inspectors, and a special department for agriculture under the minister of the interior) the market value of grain has decreased by about one-half since 1875. Permanent pasture in 1900 extended to close upon 3,000,000 acres. The number in 1876 and 1899 respectively of horses was 268,000 and 284,900 ; of cattle, 1,439,257 and 1,646,500 ; of sheep, 891,090 and 755,400 ; of goats, 150,000 and 177,200 (1898) ; of pigs, 352,000 and 1,348,500. The value of the live stock was estimated in 1897 at about £14,473,200. Stock-breeding, like agriculture, has considerably improved under the care of the Government (state and provincial), which grants subsidies for breeding, irrigation of pasture-lands, the importation of finer breeds of cattle and horses, the erection of factories for dairy produce, schools, &c.

Fisheries.—The position of the fishing industry in the four great fishing areas in 1899 was :—

	Vessels.	Men.
North Sea Fishery (Salt Herring, Cod, and Flat Fish) . . .	1,459	10,632
Zuyder Zee Fishery . . .	3,511	7,492
Groningen and Friesland Fishery .	98	288
Zeeland Fishery	1,072	2,383

The herring exported from the North Sea fishery in 1898 amounted to 354,333 tons, value £530,878 ; the herring exported from the Zuyder Zee fishery amounted to 71,380,000 fish—various fresh sea-fish, 89,027 cwt. ; salt cod, 728 cwt. ; stockfish, 63,718 cwt. ; anchovies, 43,300 ankers (an anker contains 1500–4000 fish, according to their size) ; oysters, 50,819 cwt. ; shrimps, 60,943 cwt. The great advance in the activity of the fisheries must be attributed to the use of better nets and vessels (*loggers*), improved laws and international treaties, the scientific study of ichthyology, and the connexion of the chief ports with the various railways.

Industries.—The following are the statistics of the occupations of the people :—

Industries.	Total Number of Workers.	Number of Women Workers.
Earthenware, Diamonds, Glass, Mortar, and Stone . .	28,572	2,354
Printing and Lithography .	12,105	88
Building	120,975	343
Chemical Industry . .	3,509	565
Wood, Cork, and Straw .	37,387	521
Dress and Dyeing . .	75,645	43,014
Handicrafts	1,598	221
Leather, Oilcloth, Indiarubber	37,422	624
Coal, Salt, Turf . . .	15,371	2,088
Metallurgy	41,633	457
Papermaking	2,923	595
Ship and Carriage Building .	13,516	71
Steam and other Engines .	6,456	56
Textile	44,455	10,833
Lighting, Oils, Varnish . .	6,332	485
Food and Narcotics . .	84,327	3,355
Total . .	532,226	65,670

About a third of the productive population of 1,658,000 find their means of subsistence in factories or workshops or as odd workmen. The number gaining a living from agriculture, live stock, gardening, &c., is 525,000. The factories are very unequally distributed amongst the different provinces. South and North Holland, Brabant, Gelderland, Overyssel, and Groningen combined have 3340 out of 4089 factories, 3978 out of 4812 engines, 56,968 out of the 68,278 total horse-power. Among industrial products the export of margarine represents a value of £3,725,400 ; sugar, £4,482,000 ; textiles, raw and manufactured, £7,338,300 ; paper, £3,636,000 ; vegetables, fresh and dried, £3,951,300 ; butter, £1,881,000 ; iron and steel goods, £11,877,000 ; cheese, £1,339,000 ; cereals and flour (wheaten, rye, potato, &c.), £15,996,400. By means of national and international exhibitions, museums, and schools, including those for women, the Government and various societies have considerably promoted industry.

Trade.—In 1900 the value of the imports for home consumption was estimated at £164,000,000, and the exports of home produce at £141,250,000. The following table shows the value of the imports and exports of the great classes of products for 1900 :—

	Imports.	Exports.
	£	£
Food Products . .	42,497,000	40,906,000
Raw Materials . .	38,568,000	29,022,000
Manufactured Products .	20,325,000	20,002,000
Miscellaneous. . .	29,668,000	25,109,000

Of the exports, 48·8 per cent. go to Prussia, 22·7 per cent. to Great Britain, 13 per cent. to Belgium, 4·4 per cent. to Java, 3·2 per cent. to the United States. Of the imports, 18·9 per cent. come from Prussia, 16·5 per cent. from Great Britain, 11·5 per cent. from Belgium, 13·7 per cent. from Russia, 14 per cent. from Java, 7·7 per cent. from the United States. In the total value of the imports, grain and rice represent 22·44 per cent. ; drugs, 12·96 per cent. ; iron and iron goods, 5·97 per cent. ; coals, 2·89 per cent. ; yarn, 2·43 per cent. ; coffee, 2·50 per cent. In the value of the exports, grain and rice represent 16·22 per cent. ; drugs, 14·65 per cent. ; iron and iron goods, 5·10 per cent. ; sugar, 3·72 per cent. ; butter and margarine, 3·64 per cent. ; manufactured goods, 3·44 per cent. ; coffee, 1·82 per cent., &c.

Shipping and Navigation.—The access to river-mouths and seaports has been improved by the new waterways to Amsterdam and Rotterdam (and in the case of the former town by the use of ice-breakers), by the new sluice at Ymuiden (1892–96), and by the new facilities for communication with the sea at Terneuzen (1882), Stavoren (1883–88), Harlingen (1894), Lemmer (1886–88), and Zwolle (1878). From £585,000 to £665,000 was expended between 1872 and 1897 on the building of lighthouses and lightships, in addition to £8,335,000 upon the improvement of waterways and seaports. The depth in the chief sea outlets and river-mouths is :—For the northern (*Friesche zeegat*, that for Terschelling, Texel, and Oude Vlie) 7·9–19·4 feet, for the southern (that for Goeree, Brouwershaven, the Krammer, Volkerak, Hollandsch Diep, and West Scheldt) 9·8–27·2 feet. The number of vessels belonging to the mercantile navy at the end of 1900 was 638 of 348,174 tons, of which 425 of 78,588 tons were sailing vessels and 213 of 269,586 tons steamers. In 1900 the total number of vessels which entered the ports was 12,307 of 9,475,164 tons, and cleared 12,367 of 9,449,676 tons. Of the total number entered, 3335 of 2,381,358 tons were Dutch vessels. Of the total entered, 6401 vessels of 5,816,928 tons were at the port of Rotterdam and 1884 of 1,453,170 tons at Amsterdam. About 70 Dutch steamers give passage to the colonies and other parts of the world.

Inland Communication—Railways.—Since 1890 the Rhine railway, and since 1898 the railway between Maestricht and Liége and the portion of the Central Belgian Railway on Dutch ground, have been worked by the state. The following table gives the railway statistics for 1899 :—

	Miles.		Traffic (1899).	
	1875.	1898.	Passengers.	Tons of Goods.
State Railways . .	528	972	11,733,000	7,060,000
Railway of Holland .	147	796	14,463,000	3,425,000
Central Railway . .	63	69	1,123,000	394,000
North Brabant—German Railway . .	32	63	545,000	322,000
Total . .	770	1900	27,864,000	11,201,000

The revenue of the railways was in 1900 £3,554,350, and expenditure £2,969,850. Since 1877 communication has been greatly improved by the construction of tramways (61, of which 36 are steam). Their total length was 927 miles in 1899, when they transported 53,697,000 passengers and 520,535 tons of goods. Their chief importance consists in the connexion they form

between rail- and water-ways, and the opportunity they give the working-classes of living outside the great towns. Altogether, Holland has 9321 miles of roads and dykes; these last being the embankments which shut out the sea and protect the low-lying country against the rivers.

Inland Communication—Rivers and Canals.—The corrected figures, showing the breadth and depth of the rivers in recent years, are very interesting. The expenditure upon their improvement, which from 1844 to 1861 amounted only to £791,600, rose, for the years 1862 to 1898, to £10,416,600. The normal breadth (minimum) of the fairway and depth (on the shallowest part at lowest tide) of the chief rivers are respectively as follows:—Upper Rhine, 657 feet and 10½ feet; Waal, 1017 feet and 8·9 feet; Lek, 453–738 feet and 6·6 feet; Meuse, 109–131 feet and 3·3–5·4 feet. Considerable sums have also been spent since 1874 on the improvement of small rivers such as the Dommel, Old Yssel, Berkel, Vecht, and Regge, to make them available for irrigation and canalization, and to prevent inundations. The chief canals constructed since 1877 are the Deurne canal (1876–92), depth 5·9 feet, from the Meuse to the Helena Fen (North Brabant); the Merwede canal (1881–93), depth 10·2 feet, from Amsterdam to Gorkum; the Overyssel (1884–88), depth 5·2 feet, in the province of Overyssel; the Stieltjes and Orange canals, in the province of Drenthe, depth 6·6 feet, and constructed respectively in the years 1880–84 and 1881–89; and the Groningen (1877–81), depth, 3·3 feet. The total length of navigable river channels in 1898 was 860 miles, of canals 2082 miles. The latter vary in depth from 33 to 3 feet, according to their importance as highways to the North Sea, the Scheldt, the great rivers Rhine and Waal, or as waterways between the greater towns, and as provincial canals to the fens. The inland traffic cannot be tabulated in definite figures, but its extent may be estimated by the quantity of produce brought to the public markets and the number of ships employed on rivers and canals. Of late years there has been annually brought to the market of Alkmaar about 13 million ℔ of cheese; to that of Sneek (Friesland) about 4½ million ℔ of butter; to the market of the small town of Purmerend 80,000 sheep and 50,000 head of cattle; to Leeuwarden 163,000 head of cattle; to Rotterdam more than 200,000 head of cattle, sheep, &c. The foreign shipping on the rivers in 1897 consisted of 68,712 vessels. Lobit on the Rhine was passed in 1898 by 58,546 vessels. But for inland traffic there are thousands of other large and small vessels passing the canals and sluices. Between Amsterdam and Rotterdam 26,812 ships passed in 1898; St Andries, the sluice between the Waal and Meuse, was passed by 4719 ships; 5841 ships traversed the Walcheren canal; 41,161 the South Beveland canal (Zeeland); 37,252 the Merwede canal; Zwartsluis, on the Meppeler Diep, was passed by 16,990 ships; the total inland traffic amounting to about 1,700,000 tons.

Money and Banking.—Since 1875 there has been an unrestricted coinage of ten-guilder (guilder=1s. 8d.) pieces in gold. There are no State banks. The Bank of the Netherlands is the only one having the right to issue bank-notes for a period of fifteen years from 1888, the contract being renewable for ten years. Two-fifths of the paper money must be covered. In 1901 the notes in circulation amounted to £19,322,400; total exchanges, £40,360,900; stock of gold, £6,191,700; stock of silver, £5,670,000. The capital amounts to £1,666,666; the reserve fund to £458,333. The bank keeps the State treasure and the cash of the post office savings bank. There are many savings banks, all private. Besides these there is a post office savings bank, established in 1881. The total deposits of the private banks in 1900 amounted to £6,405,600, and of the post office savings bank to £7,058,100; the number of depositors in the former was 420,885, in the latter 764,201.

Post Office and Telegraphs.—The following table shows the progress made since 1875:—

Year.	Letters.		Printed Matter.	Postcards.		Letters and Cards per Head of the Population.	Telegraph.		
	Inland.	Foreign.		Inland.	Foreign.		Miles of Line.	Miles of Wire.	Messages.
1875	35,581,000	10,344,000	50,000,000	7,545,000	259,000	14·3	2,138	6,341	2,500,000
1900	74,800,000	28,112,000	156,063,000	46,613,860	9,193,400	30·8	3,831	14,210	5,393,870

The receipts of the post office in 1900 amounted to £845,800, and expenses £645,200; of the state telegraphs, receipts £178,450, and expenses £227,250.

Colonies.—The Dutch colonies in the East Indian Archipelago cover an area of 740,193 square miles, or an area sixty times that of the mother country, with a population in 1897 of about 63,315 Europeans, 469,534 Chinese, 24,410 Arabs, 11,625 other foreigners, and 34,000,000 natives. For the West Indian colonies the area of Surinam is 57,917 square miles, with a population in 1898 of 65,168. The West Indian Islands—Curaçao (212 square miles), Bonaire (129 square miles), Arūba (64 square miles), St Martin (17 square miles), St Eustatius (8 square miles), Saba (4 square miles)—had a combined population in 1900 of 51,693. The East Indian possessions no longer (since 1893) yield an annual contribution. Their expenditure exceeded their revenue in the three years 1897–99 by the respective amounts of £1,500,000, £1,415,000, and £415,000; but in 1900 and 1901 there were surpluses of £386,656 and £4213 respectively. The West Indian colonies require aid to the extent of £15,000 to £32,000 annually.

AUTHORITIES.—Statistical: *Jaarcyfers voor het koningryk der Nederlanden* (annually).—Dr BLINK. *Nederland en zijne bewoners* (1887–92), and *Tegenwoordige Staat van Nederland* (1897).—R. SCHUILING. *Aardrykskunde van Nederland* (1897); *Eene halve Eeuw* (1848–98); *Historisch Gedenkboek* (1898), containing a series of articles on all subjects connected with the kingdom during the latter half of the 19th century, written by specialists. *Les Pays Bas* (1898), a work of the same class as the preceding. *Gedenkboek uitgegeven ter gelegenheid van het 50 jarig bestaan van het Koninklyk Instituut van Ingenieurs, 1847–97* (1898)—an excellent aid in studying technically the remarkable works on Dutch rivers, canals, sluices, railways, harbours, drainage and irrigation works, &c. A special manual on the characteristic hydrography of the Netherlands is BEEKMAN's *De Stryd om het bestaan* (1887). Amongst the publications not written in Dutch, and therefore more accessible to foreigners, may be mentioned: RÉCLUS, *Nouvelle Géographie* (1879, vol. iv.).—KIRCHHOFF. *Länderkunde von Europa* (1889, vol. i.).—BLOK. *History of the People of the Netherlands*, 1898–99.—DITCHFIELD. *The Church in the Netherlands*, 1892.—DOUGHTY. *Neerland Meres*, 1890.—*Topographische Atlas van het Koningryk der Nederlanden*, 1892; the new edition of the *Waterstaatskaart van Nederland*, of the *Rivierkaart van Nederland* (1883), and of the *Geologische Kaart van Nederland* (1889). A new edition (1895, Arnheim) of Witkamp's *Aardrykskundig Woordenboek* has been published. Of much higher rank are the *Nomina geographica Neerlandica* (for the history of geographical names) and the *Algemeene aardrykskundige bibliographie van Nederland*, giving the literature for the kingdom, the provinces, and the towns, both published by the Royal Geographical Society at Amsterdam.—D. S. MELDRUM. *Holland and the Hollanders*. London, 1899. (C. M. K.)

RECENT HISTORY.

The writer of the history of Holland in the earlier volumes of this Encyclopædia (9th ed.) broke off his narrative practically at the most critical juncture of modern Dutch political affairs in 1850. From that date the newest, and in many respects the most important, stage in the history of Holland in the 19th century may be said to have begun. When King William the Second died at Breda in March 1849, a remarkable Prince of Orange had passed away—a man of singular purpose and force of character. A born soldier, he had developed, upon Wellington's battlefields in the Peninsula, in the Pyrenees, and around Waterloo, some rare tactical gifts, and a personal valour which commanded the admiration and the lifelong friendship of the Iron Duke himself; and he enjoyed a popularity, both in Holland and in Belgium, which survived even after the Belgians had risen against the unwise and intolerant rule of King William the First, which the narrow-minded Congress of Vienna had imposed upon them. But the second King William of Holland was not a politician. He showed his lack of political wisdom in acting diametrically against the positive instructions of his royal father, who had sent him to the south with a mission which he openly ignored by issuing a manifesto to the Belgians in which he professed to recognize their independence. The king immediately repudiated that manifesto, which, without adding to his son's popularity in the Southern Netherlands, seriously jeopardized his prestige and prospects in the

William II.

north. Indeed, the wrath of the Dutch people, then highly incensed at what they branded as Belgian treason, became so violent that it was publicly proposed to exclude him from the throne. Nor was his conduct in London, whither his father sent him on another political mission, which proved as futile as his previous errand to obtain the hand of Princess Charlotte had been, calculated to regain for him the hold he had lost upon his future Dutch subjects. Not even the brilliant military campaign which he undertook in Belgium at the head of the Dutch army could, fruitless as it turned out to be, entirely restore confidence in him. So when King William the Second ascended the throne of Holland on the abdication of his father in 1840 his position could hardly be called satisfactory or secure.

Peace with Belgium had, it is true, at last been made, but that more or less beneficial settlement of the Dutch crisis abroad was perhaps more than counterbalanced by threatening internal complications. The finances had become disordered, if not critical, in consequence of the Belgian troubles; taxes had been rapidly increasing, and with them popular discontent and disgust against a *régime* which failed to grasp the fact that the flimsy reforms, grudgingly bestowed in 1840, were wholly unavailing to stem the current of national feeling which set in stronger and swifter as the fateful year 1848 approached. A wise and statesmanlike ruler would not have resisted the popular demand for a thorough remodelling of Holland's Constitution upon an enlightened basis so long as King William the Second did. But he was a soldier, not a statesman. Married to Anna Paulowna, a Russian grand duchess, he seemed to have abandoned the liberal traditions of his predecessors and of his people for the autocratic tendencies of Muscovite rule. For eight years the king withstood the efforts of the Dutch reform party, who in Johan Rudolf Thorbecke, the foremost statesman of Holland in the 19th century, and "too great a man for so small a country" (as a British statesman is said to have characterized him), had found a leader and a soul. Already in 1844 Thorbecke, with eight other members of the Dutch Chamber, had elaborated a reform Bill. Thorbecke, a student, afterwards a professor in the law faculty of Leyden University, was strongly supported by the vast mass of his educated and enlightened countrymen, then mostly unrepresented in the legislature. Yet for a time all his endeavours were baffled by the powerful court party, and Thorbecke even failed to obtain re-election as a member of the Second Chamber in 1846. His time, however, was coming rapidly. In 1847 serious riots occurred at various places, even at The Hague, and notably at Groningen. The king at last saw the danger of further delay, and, prompted maybe by the warnings of coming crisis all over Europe, he promised reforms when opening the States-General in the autumn of the same year. There is no doubt that this timely resolve warded off from Holland the threatening revolution which had broken out in neighbouring states. In March 1848 a royal commission was appointed to elaborate a new Constitution. Of that royal commission Thorbecke was much more than a member. The commission was virtually his commission, and the project it presented to the king his life-work. Its main features having been fully discussed and accepted beforehand, its progress was swift. In October following it became law, and an interim cabinet was appointed to carry out its provisions. The king's signature was practically his last political act. He died at Breda on the 17th of March 1849, and his son William, born at Brussels on the 19th of February 1817, ascended the throne (on the 21st of March) as King William the Third. But for these events, it is probable that the first ministry of Thorbecke would have been formed at an earlier date than the end of October 1849.

The reform movement.

The Prince of Orange who now mounted the throne was, in character, tastes, and ambitions, essentially different from his predecessors. During his protracted reign, extending over more than forty years, he never displayed any lofty and ambitious statecraft which might have endangered the international position of Holland, except perhaps in 1867 by the proposed sale of Luxemburg to France, and three years later when some court leanings towards Napoleon III., fostered by the anti-Prussian feelings of his first wife, Queen Sophie, a Würtemberg princess whom as crown prince he had married in 1839, threatened to embroil his kingdom in the Franco-German conflict. With the Russian blood of his mother in his veins, King William III. had inherited an autocratism ill befitting a constitutional monarch, an abrupt frankness that sometimes amounted to absolute brutality, a punctiliousness in matters political, military, and even social, not unfrequently embarrassing and humiliating to those to whom the king addressed his curt remarks. But he never could forfeit his hold upon the popular mind. The people knew that their prince meant well, that he had a kindly heart —evidenced by his noble self-sacrifice in the calamitous floods of 1855 and 1861—a sort of magnificent instinct which prevented him from acting against the interests of the nation and prompted him to follow in times of temptation and crisis the advice of his constitutional counsellors. So they readily forgave his several domestic blunders which estranged him from his first queen and drove his eldest son William Prince of Orange (born in 1840), a young man of extraordinary promise, into exile at Paris, where he died on 11th June 1879. The king did not like the austere Thorbecke, yet recognized in him a superior mind and political wisdom, born of thought, learning, and experience, and he yielded to Thorbecke's influence whenever it became absolutely necessary to do so, though not always willingly.

William III.

The preponderance of Thorbecke in Dutch political life during the latter half of the 19th century was such that the modern history of the Netherlands may be safely divided into two periods: the Thorbecke period, and the period after Thorbecke's death. The first Thorbecke ministry, formed as the natural outcome of the triumph of his efforts and principles, lasted only till 1853, but was marked by extraordinary activity. During that comparatively speaking brief period many fundamental laws were passed for which the Constitution had already provided—such as a new electoral law; a law to regulate the responsibility of ministers; another, to settle the rights and duties of provincial governments and councils, and of communal governments and councils, together establishing, in large measure, a complete system of decentralization—thus practically introducing a kind of local government in Holland half a century before it was attempted in Great Britain, but within well-defined limits and safeguards; an act to regulate the rights and duties of Dutch citizenship; another, to settle the parliamentary prerogative of inquiry, &c. In Van Bosse, Thorbecke had secured the services of an able and energetic minister of finance, who raised the state credit, abolished several irksome and oppressive taxes, and established free trade, Holland being the only Continental state that afterwards remained faithful in the main to free trade principles. The postal and telegraph services were reorganized, and the great work of draining the Haarlem Lake was completed. The first Thorbecke cabinet came to an untimely end in 1853, in consequence of what was called "The April Movement," because it had originated in that

Thorbecke's First Ministry.

month. Article 165 of the Constitution had recognized, in a country where there was no state Church, the equality of all religious bodies, subject to governmental control. The Pope and the Militant Clerical party in Holland perceived in that article an opportunity to re-establish in the Low Countries the ancient bishoprics of Utrecht, Haarlem, Bois-le-Duc, Breda, and Roermond, the bishop of Utrecht becoming an archbishop. This measure — coupled, it must be confessed, with some unfortunate reflections on Dutch Protestantism by the Pope in his decree on that occasion—revived all the anti-Catholic prejudices of former days. Some political enemies of Thorbecke, who could not forgive him his triumphs, were not loth to fan the flames, and a veritable No Popery storm swept over the country, which Thorbecke resisted but could not withstand, he himself being accused of treasonable "Papism." For several years to come Thorbecke was compelled to relinquish the active duties of leadership, and not until 1862 did he regain it. The intervening years form a sort of interregnum in modern Dutch history. Four cabinets followed each other at about equal intervals, the most important among them being the ministry of Dr Justinus Van der Brugghen. It was during his premiership in 1857 that the Primary Education Law was passed, which established neutral (non-sectarian) state schools, and afterwards largely became the pattern of similar legislation in foreign countries, notably of the Education Act of 1870 in England. The Dutch law, however, did not as yet provide for compulsory education.

It is curious to note that an article in Van der Brugghen's Education Bill, in which it was proposed to grant Government subsidies to denominational schools if parents wished it, was defeated by the Catholic and anti-Revolutionary parties, acting in conjunction with a section of Liberals—that is to say, by the action of the very people who afterwards demanded the abrogation of the same article. The preceding cabinet of Dr Van Hall, an opportunist statesman of considerable ability, was chiefly remarkable for the passing of a statute providing for the better administration of the Dutch East Indies. This is the so-called *Règlement* of 1854, or Rules of Government, which practically inaugurated a new era in Netherlands India. (See, for further particulars, MALAY ARCHIPELAGO, *History*.)

Railways.

The subsequent cabinet of Dr Van Hall carried in 1860 a most important law, directing the construction of a vast system of state railways, connecting the already existing private lines, and involving the building of very costly bridges over the broad rivers in the south. The first State Railways Act of Holland was carried, after much strenuous opposition in both branches of the Dutch legislature, very shortly after the rejection by the First Chamber of another Government scheme, which provided for the construction of certain railway lines by a private company, the state guaranteeing the capital required for construction. The defeat of the Government led to a ministerial crisis, and the new cabinet immediately took up the railway question, making it the chief plank of its platform. That the Dutch Chambers adopted the principle of state railways in 1860 was largely due to Thorbecke's influential advocacy. He pointed out that Holland was still very backward in this respect, and that the country could not successfully cope with foreign states whilst this condition prevailed. Thorbecke's main proposition was indeed self-evident. Up to 1860 only a small number of private railway companies were at work, chiefly in the central provinces, and the aggregate length of their systems did not amount to 300 English miles. Moreover, they were handicapped by the Government having too long maintained an antiquated gauge, which precluded all connexion with foreign railways having a narrower one. The State Railways Act of 1860 provided that ten million guilders per annum would have to be applied to the construction of the lines decided upon, and by 1872 the whole first network of Dutch state railways was at last completed. It is noteworthy that the cost of building them was almost entirely furnished by the surplus funds accruing annually (up to the year 1877) from the administration of the Dutch East Indies under the "culture system." Consequently the Dutch state railways are the only ones in existence not burdened with debt. The state, however, did not undertake their working. This was entrusted to a private company, founded in 1863 under the title of the Dutch State Railways (Working) Company, the state merely receiving a share in the net profits.

The important statute, constituting the "State (Privy) Council," and regulating its functions, as prescribed by the Grondwet, dates from the same legislative period, and was the work of the minister of justice, Dr Godefroi, with Thorbecke's assistance.

Thorbecke's Second Ministry.

Thorbecke came back to power in January 1862. His second term of office was marked by the same reforming energy as the first, in spite of a strenuous and somewhat personal opposition, which disgusted even some of his more fair-minded adversaries. In the four years that it lasted Thorbecke had the Secondary Education Act passed (1863), completing the work of 1857; contributed to the legislation by virtue of which the great canalization works at Amsterdam and Rotterdam were sanctioned (1863); carried his Bill emancipating upwards of 30,000 slaves in the Dutch West Indies, at the cost of ten million guilders in compensation, paid by the state; and, last though not least, brought about the Financial Administration Act for the Dutch East Indies, which determined the right of the Dutch Chambers to control Dutch-Indian ways and means, thus consolidating the *Règlement* of 1854. A dispute with the colonial minister, Mr Franssen van de Putte, led to a fresh cabinet crisis, and to the advent of Mr Heemskerk, the leader of the Conservative party. Heemskerk was Thorbecke's great antagonist, the two Dutch statesmen playing in the political arena parts somewhat resembling those of Gladstone and Disraeli in England. Heemskerk, who died in 1880, and who stood three times at the head of affairs, was a politician of talent, though of less calibre and moral fibre than Dr Van Hall, his greater predecessor, and his reactionary tendencies and views found favour at court and led to legislative proposals and measures which were not always in accord with the spirit at least of the 1848 Constitution. A real constitutional crisis of some duration ensued, a struggle between the Government and the Second Chamber, during which Heemskerk attempted to shield himself behind the Crown, but in vain. There is little doubt that the king's proposal, in 1867, to transfer Luxemburg to France, if it did not emanate from Heemskerk, had his warm approval. It was none the less dangerous, especially as it came after Sadowa, which had settled the German question in a manner not at all favourable to Napoleonic ambitions. It was perfectly well known that France had coveted the grand duchy for some time as a sort of compensation for loss of prestige on the Rhine. Equally notorious was it that Bismarck, the arbiter of Germany's destinies, had no backing for his methods and aspirations from the king and queen of Holland. The Iron Chancellor was, indeed, well aware that Queen Sophie's former feelings of friendship and admiration towards him had greatly changed since the days

International difficulties, 1866-70.

of 1866. It was to her animosity that he ascribed both the hostile attitude of the South Germany States (particularly Würtemberg, her native kingdom), when they combined with Austria against Prussia, and their previous coquettings with Napoleon III. In his *Reminiscences*, published after his death, Bismarck refers to the "relations between Stuttgart and France, which were chiefly maintained by the partiality of the queen of Holland, a Würtemberg princess," and he goes on to declare that he also traced her "evil" influence in Napoleon's foreign policy of 1867, especially in the speech Rouher made in the French Senate, March 16, when the latter announced that France would never tolerate Prussia's advance towards the Zuyder Zee. Rouher, said Bismarck, could not have spoken as he did on that occasion without some inspiration from The Hague; before receiving it, the French minister probably did not even know of the existence of a Zuyder Zee!

Queen Sophie, then, belonged to the most unflinching and ablest opponents of Bismarck's policy. She corresponded much with Napoleon III., and wrote articles in the *Revue des Deux Mondes* against it. In 1871, after the sacking of the Tuileries, among many documents discovered were a large number of the queen's letters to Napoleon. Some were subsequently published, and demonstrate that she repeatedly warned him against the designs and armaments of Prussia. "But," says Lord Malmesbury in his *Memoirs* (ii. 370), "her warnings and counsels were laid aside and unheeded, like those of Stoffel, the French military attaché at Berlin." "The queen," he adds, "was a very clever woman, and knew all the affairs of Europe better than most ministers." Nor was Queen Sophie loth to reveal her antipathies towards Greater Prussia, at least among her English friends, who were both numerous and influential. Henry Reeve was one of them, and his *Memoirs* (published in 1898) contained some remarkable letters from the queen. In answer to Reeve's request for some Luxemburg papers, Queen Sophie wrote (in English): "Such is the fear of the kingdom of the Netherlands to be involved in any of the impending Luxemburg difficulties, that everything relating to that part of the world is scrupulously ignored; and if the papers are not claimed at Luxemburg, where the most jealous of men, Prince Henry, governs, you cannot obtain the real truth. The fact is, M. de Bismarck *a cherché une querelle d'Allemand*, first to obtain a free passage through the Luxemburg railroads; in the future, to annex the little grand duchy, to close the frontier on that side entirely. This, however, is still kept for a few months hence, as M. de B. would not be put quite on the same line with Prince Gortchakoff, though they are perfectly of the same opinion. It is a sad time, a very bad symptom, when principles, engagements, treaties, are all *à la merci* of two or three unscrupulous men."

The dangers foreshadowed or undergone in 1866–67 were accentuated four years later, during the Franco-German complications, ending in the downfall of the French empire. Like Belgium, Holland was put upon her trial in guarding her frontiers and her neutrality between two powerful neighbours engaged in a deadly struggle, with a court notoriously, if not openly, inimical to one of them, at least during the early stages of the contest. Fortunately a Liberal cabinet had succeeded, with some difficulty and not without struggle, to the perilously reactionary ministry of Heemskerk and Van Zuylen in 1868. It had carried through some useful reforms, such as uniform inland postage and the abolition of the newspaper stamp duty—the abolition of the death penalty in Holland belongs to the same legislative period—and the Fock cabinet succeeded in keeping the Netherlands outside the war arena. Sedan, needless to say, profoundly affected Queen Sophie, even apart from the great triumph of Bismarck; but, staunch in her friendships and antipathies alike, she never forsook the fallen emperor. Henry Reeve again records this in his *Memoirs*. When the *Edinburgh Review* had published in January 1871 an article severely condemning the Second Empire, Queen Sophie sent Reeve from The Hague a dignified protest, in which she observes: "Allow me to regret the great severity with which you treat the fallen empire. I put aside every personal feeling, but I remain convinced that posterity will be more lenient. There were faults in the system inherent and inherited. As to the head of the system, few men have been more naturally kind and good. He had the weakness of these natures—wishing to content every one. No question of principle seemed to him worthy of the inestimable enjoyment of peace. *Avec les differents partis il se laissait aller à des paroles, à des engagements contradictoires; de là une apparence de dissimulation, bien éloignée de sa nature.* The prisoner of Wilhelmshöhe belongs to the past. To those that have known and loved him falls the task of obtaining justice for him. I cannot talk of the present events, of the destruction of Paris. I bow my head and I hope in God's justice."

The king sent for Thorbecke again in January 1871, in this instance for the third and last time. He succeeded in forming another ministry, but he was no longer the Thorbecke of yore. Much aged, and feeble in health, soured by continued strife and opposition, he found the state of affairs in his country materially altered. The Liberal party, once all-powerful under his guidance, was no longer so compact, so obedient to his directive impulses, his masterful discipline. Many years had passed, many changes had occurred since the Constitution of 1848 was enacted, and even among Thorbecke's admirers and followers there were not a few who felt that it had served its purpose, and required enlargement of scope to suit the needs of a new generation. Thorbecke himself, indeed, had recognized this only three years before his death. Yet many doubted his power to carry through that revision of the Constitution which experience had taught to be necessary, whilst others derided even the breadth of his views and the generosity of his policy, contending that Thorbecke had become at heart a Tory, autocratically narrow in his opinions, particularly upon matters religious, colonial, domestic, and artistic. It was a curious spectacle to see those who in 1853 had denounced Thorbecke as a Papist bitterly attacking him in 1871 as an enemy of the Roman Church, because he defended the recall of the Dutch minister at the Vatican when the Italians had taken possession of Rome. The groups in Holland, acting in opposition to Thorbecke's cabinet from various motives, had latterly grown more powerful, some demanding an extended suffrage, others the revision of the Education Act, factory laws, and other reforms. Each faction, in truth, was not strong enough to work much mischief, but, supported by the Extreme Liberals, or united with the so-called anti-revolutionary party of Mr Groen Van Prinsterer and the Roman Catholics, against the statesman who had refused to admit the clerical grievances against the non-sectarian state schools, it undoubtedly ceased to be a *quantité négligeable*. At any rate, before Thorbecke died, in June 1872, he must have been conscious that his death might mean the partial disruption of the party he had created, as well as the shattering of the edifice he had been instrumental in building up. His cabinet did not survive for long under the leadership of his successor, Dr Geertsema, and finally disappeared in August 1874, after having had its Income Tax Bill rejected. Its most important measures had been the further extension of state railways

Death of Thorbecke.

in Holland (1873) and her colonies, the abolition of differential import duties in the Dutch East Indies, and the transference of the remaining Dutch portion of the Gold Coast to the British Government for a sum of money and certain British "concessions" in the Eastern Archipelago. This transaction, which shortly afterwards resulted, on the one hand, in the Ashanti expedition, and on the other in the disastrous war of the Dutch against the Achinese, had been one of the many weapons used by the Opposition against Thorbecke.

Thorbecke's last illness would have commanded a keener national interest than it did but for the fact that it was thrust into the background by the festivities to celebrate the three hundredth anniversary of the capture of Briel on 1st April 1572, which signalized the commencement of the great struggle against Spain. In the spring of 1874 festivities on a much larger scale than those at Briel took place all over Holland when King William celebrated the twenty-fifth anniversary of his accession to the throne. They were particularly brilliant at The Hague and Amsterdam, and the enthusiasm of the people was as genuine as it was unbounded. It was the last time that the nation saw the whole royal family of the Netherlands together, apparently happy and in good health. Many knew that Queen Sophie had latterly suffered from illness, but few suspected her end to be so near. "Full of charity, constantly occupied with thoughts of others, forgetful of self, and deeply interested in all great subjects which occupy the attention of the more elevated intellects," as the historian Motley described her, Queen Sophie died at The Hague in June 1877. As far as the Dutch royal family were concerned, the effect of Queen Sophie's decease was absolutely disastrous. The quarrels between the king and the Prince of Orange, who had inherited the wit and the mind of his royal mother, and who if he had lived might have proved one of the most distinguished of his race, became aggravated when the wife and the mother was no longer there to conciliate and pacify. Father and son parted, never to see each other again. So estranged had he and his father become, that the prince was even absent from the king's wedding in January 1879 at Arolsen.

Death of the Queen.

It is at least probable that the departure of the Prince of Orange for Paris, and the unlikelihood of his return to Holland during the lifetime of his father, may have had as much bearing on the king's decision to re-marry as the circumstance that his second son Alexander, who succeeded to the title and presumptive rights of the Prince of Orange after the decease of his elder brother, but who died in 1884, was then in very bad health. The direct Nassau line was threatened unless King William were to marry again and had further issue. His bride was Princess Emma of Waldeck-Pyrmont, and by the marriage King William consolidated his popularity. Popular rejoicings greeted the birth, on the last day of August 1880, of a princess, who received the name of Wilhelmina Sophia Frederika and the title of Princess of Orange. Two years later the king, accompanied by his queen, went over to England to attend the marriage of Queen Emma's sister to the Duke of Albany.

The King re-marries.

The second ministry of Dr Heemskerk had terminated in November 1877, and was succeeded by that of Dr Kappeyne van de Copello, who in the following March was able to persuade the Chambers to adopt his Primary Education Bill, strengthening the Act of 1857, despite the violent opposition offered by the reactionary parties, who continued it even after the Bill had passed, petitioning the king (but fruitlessly) to veto it.

Up to the year 1880 Dutch politics, externally, were largely dominated by events in Achin, where the new arrangements with Great Britain, materially modifying the treaty of 1824, had given Holland a free hand, of which she had not failed to avail herself, although the subjugation of that sultanate proved much more difficult and more costly—especially in its after results, an endless and wasteful warfare — than had been anticipated. Internally, the second ministry of Heemskerk, succeeding that of Geertsema, had to cope with a hostile Liberal majority in both Chambers, which hampered it greatly, and it was not able to do much more than add the Higher Education Act to the statute-book. But that measure was very comprehensive and important. It regulated and equalized in 1876 the three state universities of Leyden, Groningen, and Utrecht, enabling Amsterdam to establish a communal university with equal rank in 1877, and the anti-revolutionary party to found a free university of its own in 1880. Not much progress had, however, been made with two other reforms of great national importance: first, a new codification of the criminal law — the old Napoleonic Penal Code introduced in 1810 being still the law of the land; second, the framing of a new Constitution, to replace Thorbecke's Grondwet of 1848. Although the former reform was carried in 1881, it did not come into operation till January 1886. Professor Modderman of Leyden, head of the department of justice, was largely instrumental in the passing of the measure during the ministry of Count van Lynden, who had succeeded Kappeyne van de Copello as premier; and his friend and colleague, Dr Vissering, the minister of finance, carried through the Bill establishing post office savings banks.

Political progress.

The revision of the old Constitution, which had been prepared by a royal commission, proved an even more arduous and more laborious task than that of the penal code. Thorbecke had, perhaps wisely, made the tampering with the Fundamental Law of 1848 as difficult an undertaking as possible; one of the final clauses provided, for instance, that proposals affecting succession to the throne, and the modification of the Constitution, could not be entertained during a regency—the very thing that was likely to happen in Holland if the king died during the minority of the Princess of Orange. The alteration of this clause had therefore to be undertaken first (1884) before the revision proper could be made. The death of the Prince of Orange (1879) and the birth of a daughter to the king had for the moment brightened the chances of such revision. Seeing that it had become a national necessity, Dr Kappeyne van de Copello, when prime minister, had made revision a plank of his platform, but by a curious freak of fate it was not he, but his reactionary successor Heemskerk, who carried the revision scheme through in 1886.

Constitutional revision.

The new Grondwet, or Fundamental Law, came into force in 1887. This statute comprises eleven chapters, apart from some "additional clauses" concerning the method of carrying it into effect. The first chapter treats of the kingdom and its inhabitants, and declares that the Fundamental Law is applicable to the Netherlands alone, and not to the Dutch colonies. Dutch citizens only may hold appointments; but liberty of speech, of the press, of meeting, and of petition, and the rights of property, are guaranteed to all residents. Chapter ii. (Succession to the Throne) declares that the crown may pass to a female, who, however, will forfeit the crown if she marry without the consent of the States-General. The latter may, in default of any heirs, elect a king (or queen) in an extraordinary combined session of the two

The Constitution of 1887.

Chambers. No king is allowed to wear a foreign crown, and the seat of government may not be established outside Holland. The civil list for each reign must be fixed by a special law. During a minority of the king or queen, or should he or she become unable to govern, the two Chambers may appoint a regent. The oath to be taken by each king or queen on ascending the throne is given in the Fundamental Law, and shows that the regal rights in Holland are conferred by special contract between the people and the crown, and not inherited of divine right. The king is inviolable, but his ministers are responsible. The king declares war, makes and ratifies treaties with foreign Powers, and has the general direction of foreign affairs, but no treaties with foreign Powers, involving territorial changes, or affecting public rights as established by statute, are valid unless sanctioned by the States-General. The king also has the supreme control of the state finances. He confers ranks and titles; has the right of pardon, of initiative of Bills in the Second Chamber, and may sanction or reject measures passed by both Chambers; he also possesses the power of dissolving the latter, and nominates the members of the Council of State, to which he submits all Bills intended to be presented to Parliament. He also appoints and dismisses all ministers whose responsibility is regulated by special statute. According to the third chapter, the States-General represent the whole people, being divided into a First and a Second Chamber, the former consisting of fifty, the latter of one hundred members—Amsterdam returning nine, Rotterdam five, The Hague three, Groningen and Utrecht two each. This was an important addition of strength, the old Second Chamber having had at most eighty members, one for every 45,000 of the inhabitants. The basis of the franchise was at the same time materially altered and much enlarged, the effect being to add some 200,000 male voters of the age of twenty-three to the electorate, the rights of the latter being afterwards settled in a special statute. For the First Chamber, however, the old basis (election of delegates by the provincial states from among the highest taxed or otherwise prominent burghers in each province) was maintained, each member being elected for nine years, one-third retiring every three years. The members of the Second Chamber are elected for four years, when the whole retire in a body. The members of both Houses receive certain allowances from the Treasury to meet the expenses of their journeys to and from The Hague, and of their residence there during the session. The Second Chamber alone has the right to initiate legislation, and the First Chamber does not possess the right of amending any Bill sent up to it by the other Chamber. Ministers may attend the sittings of each Chamber, but are not allowed to vote unless they are members themselves; no one can be a member of both Chambers simultaneously. No male person is eligible who has not attained the age of thirty. The fourth chapter deals with the provincial states, elected by the people directly in the eleven provinces, in each of which there is a royal commissioner who presides over the provincial assemblies. The communal councils, with presidents (burgomasters) nominated by the king, are also elected by the people of each commune, but are under the control of the provincial states. The fifth chapter treats of the administration of justice, and the sixth of public worship. The latter guarantees freedom and equality of rights to all religious bodies, the clergy receiving a salary and a pension from the State. The seventh chapter deals with the national finances; the eighth with national defence, declaring all able-bodied citizens liable to serve in the army, reserve, or militia; and the ninth with the *waterstaat* (dykes, roads, bridges, dunes, &c.). The tenth chapter, dealing with public education and poor law administration, sets forth that both are a constant concern of the Government. Although the clauses of this chapter are seemingly the same as the corresponding clauses in Thorbecke's Grondwet, yet it was perfectly well understood, when the Constitution Bill was passed, that they must be interpreted in a sense widely different from that which the legislators of 1856 had imparted to the Primary Education Act of the following year; for that Act established, as we have seen, primary State schools upon a non-sectarian basis, and this led to a bitter campaign on the part of the Church parties, which was renewed in 1878 against Dr Kappeyne's even more stringent educational policy. They maintained that the State had no right to "withhold the Bible" from the school children, or, by refusing State aid to private (denominational) schools, starve the latter out in order to promote a "neutral" instruction of which they could not conscientiously approve. The Roman Catholics and the orthodox Protestants had therefore insisted upon the abrogation of the Education Act of 1878, and the passing of another statute to remedy their grievances. With the aid of a section of the Liberal party which sympathized with their anti-revolutionary and Catholic countrymen in this respect they were able to enforce their views, and the introduction of a new Education Bill, which under the ministry of Baron Æneas Mackay became law in 1889, was in the nature of the redemption of a pledge. In accordance therewith the Act of 1889 was a virtual reversal of the Liberal education policy adopted in 1857–78, for it contained the following important provision: "The State will, in each governmental budget, allocate to the private primary schools subventions proportionally equal to those granted to the communal [public primary] schools." Thus it not only placed the sectarian lower schools upon a basis of equality with the public primary schools, but might even be regarded as favouring the former at the expense of the latter. It is fair to add, however, that the effect of what was virtually a compromise was to set at rest for some time to come a long and bitter controversy. Another important clause in the Act of 1889 was to the effect that gratuitous instruction was no longer possible, except in the case of pauper children.

Education Act of 1889.

The necessity of the new Constitution had already been demonstrated early in 1889, when the king's alarming condition, physical and mental, had compelled the appointment of a regent. In Luxemburg, indeed, where, owing to the Salic Law, a queen could never reign, the heir-apparent to the grand duchy, the Duke of Nassau, had already assumed the regency, in the general expectation that King William would not recover. But by May 1889 the king recovered as suddenly as he had collapsed, and his physicians having reported that his Majesty was again in a fit state to govern, the Duke of Nassau took a somewhat hasty departure from Luxemburg, whilst the States-General of Holland resolved to invite King William to resume the government, the services of a regent being no longer required. This was accordingly done, and shortly afterwards the fortieth anniversary of his accession to the throne was celebrated with some pomp. But the king's restoration to health proved of short duration. In September 1890 the ministry reported a recurrence of the alarming symptoms of the year before. A consultation of physicians again took place in October, and they reported that the king could no longer perform his regal duties. The prime minister thereupon introduced, and

Death of King William.

carried, a Bill vesting the royal power for the time being in the Council of State. The king growing steadily worse, and the end, to all appearances, rapidly approaching, a further Bill was introduced and passed, appointing Queen Emma regent of the Netherlands during the minority of the Princess of Orange, a council of guardians for the latter being also nominated. One of the guardians was Baron van Goltstein, who afterwards became the Dutch minister in London, a post he was holding when the young queen, then (1895) still in her teens, visited London, accompanied by her royal mother and by more than one of her tutors.

The Regency.

On 23rd November 1890 King William died. In different circumstances the death of the king might have been productive of serious and even critical results to the Dutch people. As it was, the event did not occur unexpectedly, and there had been ample time to prepare fully for all emergencies, while it brought at least one unmistakable advantage—namely, the complete severance of the connexion with Luxemburg. Yet at the end of 1890 Queen Wilhelmina was a mere child, and although the queen-regent and the council of guardians could be trusted to perform their duty to the new sovereign and her people conscientiously, still a difficult period was before the nation until the young queen should ascend the throne, upon her attaining her majority eight years later. That critical time, however, was passed without serious disturbance. Queen Wilhelmina's health remained good, and through Queen Emma's untiring devotion she received a good education, and gave general pleasure by her simplicity of manner, natural charm, intelligence, and force of character.

One of the chief legislative events of the year 1890 was the purchase by the State of the Dutch–Rhenish railway, the working of its lines, leading from the chief coast towns to the German frontier, being entrusted to the States Railway (Working) Company. That purchase was followed by the so-called railway agreement, dividing the whole railway network into two chief systems of State railways and of the lines of the Holland Railway Company. The effect has therefore been to centralize the working of the Dutch lines in the hands of two powerful companies, subject of course to a rigid Government supervision. This arrangement only leaves out a few minor railways, but it has been largely supplemented by a growing network of canals, light railways, ordinary, steam, and electric tramways, the vast extent of which is indicated in the statistical article above. The international railway relations of Holland, whose railway companies formed part of the Continental Railway Union before 1890, were satisfactorily settled by the Convention of Bern signed in October of that year.

In August 1891 an apparently strong Liberal cabinet had been formed under the leadership of Dr van Tienhoven. Its moving spirits were the distinguished economist and financier, Dr Pierson, and Dr Tak van Poortvliet, a former minister of commerce, who had shown great ability in promoting railways and canals, and who was a staunch supporter of national steamship lines to England and the Dutch colonies. Dr Tak was an advanced Liberal, and had a fair majority at his back in the Second Chamber, but his franchise proposals in 1894 led to a ministerial crisis and his own downfall. Undoubtedly they were too drastic, practically involving universal manhood suffrage, which by many of Dr Tak's own followers was considered unconstitutional, *i.e.*, in conflict with the Fundamental Law. Dr Tak tried to gain his ends by an appeal to the electors, the Second Chamber having been dissolved in March 1894; but a portion of the Liberal party combining with the anti-Liberals, and being supported by the most influential Liberal daily paper of Holland, the Government was defeated at the polls, and Dr Tak, finding himself in a minority, had to resign. Electoral reform was then taken up by Dr van Houten, his successor as minister for home affairs in the Roëll cabinet. He succeeded in carrying his measure, which was, however, conceived on much more modest lines than the ambitious attempt of Dr Tak. Van Houten's Bill, which abolished the *scrutin de liste*, introduced the lodger franchise, and virtually made every male citizen capable of supporting himself and family a qualified voter, passed the Second Chamber in June 1896, and the First Chamber in the following September. It was the most far-reaching electoral reform yet attempted in the Low Countries, as it not only largely increased the number of voters, but extended the suffrage to social strata hitherto deprived of all franchise rights. Nevertheless many reformers still demand, if not universal suffrage for men and women alike, at least a large service franchise, proportional representation, and reform in the election of the First Chamber. They ask also for a new revision of the Fundamental Law, without which, it is admitted, such reforms could not be obtained.

Electoral reform.

In the concluding years of the 19th century the ministerial efforts in Holland, under the influence of Dr N. G. Pierson, formerly president of the Netherlands Bank, and a distinguished professor of political economy, mainly consisted of financial and labour legislation. The state finances, much improved by the first conversion of the 4 per cent. state debt into $3\frac{1}{2}$ per cent., which was carried through in 1886 with the assistance of the house of Rothschild in London, underwent a further amelioration in 1893 and 1894 by the imposition of taxes on capital and on industrial, commercial, and professional incomes not derived from capital; and in 1896 by a fresh conversion of the $3\frac{1}{2}$ per cent. state debt into 3 per cent. The Dutch state debt was in 1902 composed mainly of $2\frac{1}{2}$ and 3 per cent. consols, the only exception being about 3,000,000 guilders of bonds, bearing 5 and 6 per cent. interest, a responsibility which the Government acquired when it took over the old Dutch–Rhenish railway. Dutch labour legislation, tentatively commenced in 1874 by Dr van Houten's mild Factory Law, which prohibited child labour in factories for children under twelve years of age, has taken great strides. In 1889 the Factory Law was much enlarged. Women, and children under the age of sixteen, are not allowed now to work at night or on Sundays, nor more than eleven hours in the daytime, with one hour's interval for meals. Mothers are not allowed to work in factories until four weeks after their confinement. State inspection of factories and workshops has been made much more stringent by a special statute, passed in 1895, which in matters of ventilation, light, hygiene, &c., seems moulded after an English pattern. Agricultural labourers and servants are not yet in possession of similar protection, but some have already commenced to agitate for it. Compensation to workmen in factories and workshops, to be paid by their employers, has also been enacted, and old age pensions have been discussed. Moreover, an important law has been added to the statute-book, instituting chambers of labour in all the more considerable industrial centres, composed of an equal number of masters and men, elected as delegates in each trade or industry. These bodies act as advisory boards in ordinary times, and as conciliation boards in the case of disputes, strikes, or lock-outs, but they have no power to enforce their decisions.

Financial and labour reforms.

Holland's foreign relations between 1850 and 1880 were

not always of a smooth and pleasant nature, and if peace remained undisturbed, at least in Europe, it was not because there never arose any dangers to threaten it, but because a skilful diplomacy succeeded in avoiding them. We have seen the perilous complications of the Luxemburg question, in which a European war was, as we now know, merely averted because Germany was not ready to strike in 1867. But the Limburg question, dating from a still earlier period, had its pitfalls too, though these were of a dissimilar nature. They were the outcome of one of the many mistakes of King William I. In 1839 he joined the Germanic Confederation for Limburg only. The hazards of this dual position for that province might have been terminated in 1848, when the Germanic Confederation ceased to exist, but the Dutch Government deliberately chose to renew them in 1849, by joining, again for Limburg alone, the federation of German States which had then been formed. While peace lasted the Limburg dangers remained in abeyance, but they became apparent in 1859, when France and Italy were at war with Austria, and when the German Confederation decided to mobilize a portion of its troops. Limburg—that is, Holland for her province—was then called upon to furnish a contingent, and this was kept in readiness for all emergencies. If a war had then ensued between Germany and France, Dutch troops might have been fighting on the German side, thus embroiling Holland in a quarrel which did not concern her. Fortunately, when the German Confederation came to an end in 1866, Holland did not join the North German Confederation, and thus the anomalous position of Limburg disappeared. When the Luxemburg and Limburg questions had been finally disposed of, Holland's international status was materially strengthened as a result of the war of 1870, and the ground was cleared for a political rôle in Europe, if less ambitious, certainly more congenial to a people so essentially peace-loving as the Dutch.

Foreign relations, 1850-80.

So far as foreign relations since 1880 are concerned, these have been cordial with Germany, neither the opinions of some Germans, that Holland ought to be annexed or acquired, nor the efforts of isolated Dutchmen to bring about a federation with Germany finding much favour. The question of the navigation of the Rhine had been solved by the abolition of tolls along the whole course of the river from Basel to Krimpen and Gorkum (1867), and by the appointment of an International Board which should settle all disputes arising from the interpretation of the Rhine Navigation Act (1868) and subsequent regulations and enactments. Upon more than one occasion this Board rendered useful services, notably in 1893, when it decided in favour of Holland concerning the long-disputed claims of Rotterdam in the matter of its harbour dues. The Rhine fisheries difficulty was terminated much later, in 1885, by the Salmon Fishery (Rhine) Convention, signed at Berlin. Its main provisions, which are equally applicable on the Moselle, provide a close time for salmon, which varies according to locality, and forbid Sunday fishing altogether. The relations of Holland and Belgium had been occasionally strained, particularly before 1863, owing to Holland's maintenance of tolls on the river Scheldt, which was of course detrimental to Antwerp, and owing also to the building of a Dutch state railway to Flushing, which involved the laying of a dam across one of the branches of the same river. Belgium contended that Holland had not the right to dam up the eastern Scheldt, which must in course of time unfavourably affect the navigable channel in the western Scheldt, and an acrimonious international controversy ensued. But in both cases Holland gained her point. The Scheldt tolls were abolished in 1863, but Holland received £750,000 in compensation, paid by the states whose ships used the Scheldt most, Great Britain contributing £175,650. In the case of the western Scheldt the protests of Belgium remained unavailing. These questions and quarrels removed, the relations with Belgium became more than cordial, both nations realizing that together they might offer a more effective barrier against the encroachments of strong neighbours than separately. What has probably contributed to this *rapprochement* is the miscalled "Flemish" movement in the Dutch provinces of Belgium, which is really a revulsion of feeling among the Dutch-speaking Belgians against the French usurpations and encroachments of the Walloon minority, all of which having been gradually swept away, Dutch is now as much the official language as French in the Belgian parliament, law courts, and government offices. The scheme, however, of many enthusiasts for a *zollverein*, or even for a political federation, between Holland and Belgium has not yet taken practical shape. With England relations were not always of an entirely amicable nature. Friction occurred in the Eastern Archipelago—not easily preventible perhaps in so vast an area, with rival interests and tendencies everywhere side by side. The most formidable case arose in Borneo, caused by the British Government, in the autumn of 1881, granting a royal charter to the British North Borneo Company, which had taken over certain territorial concessions given by the sultan of Brunei on the north-western coast to Mr (afterwards Sir) Alfred Dent and other British merchants of Singapore and Hong Kong. The Dutch Government protested against the charter, founding its protest, as in the case of Sarawak, on the Anglo-Dutch treaty of 1824, contending that this treaty placed Borneo outside the sphere of British interests in the Malayan Archipelago. Some correspondence ensued, the British Government arguing that territorial acquisition by a chartered company did not imply territorial acquisition by the British Government. The Dutch Government would not admit this, but had finally to acquiesce; and subsequently a British protectorate was declared (in 1888) over the entire northern portion of Borneo not previously claimed by the Dutch, a British resident was appointed in Brunei, and Labuan was transferred (two years later) to the control of the British North Borneo Company. In June 1891 a treaty was concluded between Great Britain and Holland, whereby the new boundaries of their respective possessions in Borneo were definitively settled. The partition of New Guinea between Great Britain, Germany, and Holland was accomplished in 1895. A similar friction more than once arose in Sumatra over Achin, the contention of the Dutch being that the tough opposition to their rule was encouraged and fed by certain parties at Singapore, despite the action of the British authorities there, who maintained for many years a prohibition of all export of arms to Achin. The difficulties assumed a critical character in November 1883, when the British merchant vessel the *Nisero* was wrecked off the coast at Tenom, and her captain and crew captured and taken into the interior by the raja. Some died, and the remainder were only rescued some months afterwards by the payment of a ransom and compensation, but not before a somewhat heated correspondence had passed between London and The Hague. A similar thing happened again in 1894, when in another part of the Malay Archipelago Mr Carpenter, the captain of the British merchant vessel the *Costa Rica Packet*, was detained and punished by

Foreign relations, 1880-1900.

the authorities of Macassar. But this incident was closed in 1895 by arbitration and an award in favour of Great Britain. The issue was the more satisfactory, because arbitration had been resisted in this instance by an influential party in Holland. The advocates of international arbitration, however, pointed out with truth that this principle had been admitted in many of the Dutch treaties with foreign Powers, notably with Italy (1884) and Belgium (1892), concerning actions at law, *pro Deo*, by the subjects of either country in the other; with Portugal (1893) relating to boundary questions in Timor, &c. Moreover, the policy of Holland, steadily pursued ever since Baron van Goltstein, the minister of foreign affairs, circularized her representatives abroad in 1860 in support of the policy of the United States, which proposed great reforms in maritime law, has always tended towards minimizing the risks of international strife by substituting the pacific adjustment of disputes for the arbitrament of the sword. That policy culminated in 1899 in the Peace Conference at The Hague and the formation of a permanent international court of arbitration, Holland taking a prominent part in both. Of course a small country cannot wield the influence of a great Power, yet the example and the policy of Holland left a distinct impression on international politics in more directions than one during the second half of the 19th century. Thus she played an important rôle in the Congo Conference at Berlin (1885), which resulted in the creation of the Congo Free State; and it was mainly due to her efforts that the conference, in the interest of the Dutch settlements on the Congo, decided that for twenty years no import duties were to be levied in the new Free State. It is true that Holland was unable to resist the reversal of these free-trade principles which the Brussels Conference enacted in 1890. The magic of a great name, and the respect which her historic traditions inspired, were not less conspicuous at the Suez Canal International Conference in 1885 at Paris, convened for settling the future status of that waterway. Holland had not originally been invited, but, considering that the number and the tonnage of her ships passing through the canal were only less than those of two other European Powers, it was ultimately decided that she had a right to be represented. During the proceedings her two delegates were able to influence the decisions in matters of great political and commercial moment to the nations interested in the Suez Canal, and Holland is one of the states charged with the joint control instituted by the Conference and the signatories of the 1888 treaty.

Within a more restricted sphere of international politics the influence of Holland made itself equally felt. In 1880 special inquiry instituted by the British Government revealed an extraordinary state of lawlessness among the fishermen of various nationalities on the North Sea. By its invitation a conference of the Powers interested met at The Hague (October 1881), and the result was a treaty, signed in the following May, chiefly remarkable as the first attempt at an international police on the high seas, in which all the Powers interested (except Sweden and Norway) afterwards participated. The new system worked very well, but it did not include the control of the liquor traffic, the abuses of which had been mainly responsible for the lawlessness. That traffic was regulated by another treaty, signed in November 1887, after a second conference at The Hague of delegates of the same Powers.

The Boer question.

Another source of diplomatic and popular friction between London and The Hague was furnished by the Transvaal question in 1881. The Boer war of that year roused extraordinary interest and excitement among the Dutch, who somewhat suddenly remembered that the Boers were their descendants and had a claim on their admiration, if not their affection, as kinsmen. Under pressure the Dutch Government offered to mediate between Great Britain and the Boers, but its services proved unnecessary, as Mr Gladstone had determined to restore the independence of the Transvaal. The Jameson Raid (1896) and the second Boer war (1899) again caused intense excitement and pro-Boer enthusiasm in Holland, coupled with a growing resentment against the British Government. No doubt circumstances had much changed since 1881, but that did not make Dutch feelings less keen, for after 1881 Holland had acquired important material interests in the South African Republic, especially in its railways, banks, and several industries, though not in its gold mines. Dutch pro-Boerism had therefore ceased to be purely sentimental, albeit it had latterly done much to promote Dutch emigration and education in the Transvaal. Holland, however, maintained a strict neutrality, and it is upon record that the Dutch Government, in the autumn of 1899, advised President Kruger not to enter upon the war with Great Britain. An attempt at mediation, based partly upon the provisions of the Peace Conference, failed; and a renewed offer at the beginning of 1902 to institute peace preliminaries—without, however, any authority from the Boer leaders—was politely declined by Great Britain.

Marriage of Queen Wilhelmina.

The young queen attained her majority in 1898, and was solemnly enthroned in the so-called New Church in Amsterdam, taking her oath of fidelity to the Constitution in the presence of the States-General on 6th September, in accordance with the ceremonial prescribed, amid national festivities and rejoicings which lasted several days and concluded with a naval review on the Hollandsch Diep. In October 1900 the announcement that the young sovereign was betrothed to Duke Henry of Mecklenburg-Schwerin, a Prussian officer of the guard, four years her senior, was well received. The approval of the States-General, prescribed by the Constitution, was therefore readily obtained, and the marriage was solemnized with great pomp in the Great Church at The Hague on 7th February 1901, Duke Henry having been created a prince and a general in the Dutch army for the occasion, under the title of Prince Henry of the Netherlands, thus happily reviving the popular title of a popular prince, King William's brother, which threatened to be extinguished with his demise in 1879.

The June elections for the States-General proved disastrous to the Liberal ministry of Dr Pierson, owing to dissensions among his following anent several important points of home policy. The combined Clericals (Catholics and Ultra-Protestants, or so-called Anti-Revolutionists) gaining a decisive victory at the polls, the Pierson cabinet tendered its resignation. Queen Wilhelmina then sent for Dr Abraham Kuyper, for many years the leader of the Anti-Revolutionary party in Holland, who succeeded in forming a ministry, in which representatives of that and the Roman Catholic party held office together. Its programme, as reflected in the speech from the throne in September, was a "Christian-National" policy, both at home and in the colonies. It has merely to be added that amongst the last achievements of the Pierson cabinet were the enactment of compulsory education (1900) and the introduction of obligatory military service consequent upon the reorganization of the Dutch army (1901).

This survey of Dutch history indicates the enormous strides that have been made in every direction since 1850.

Conclusion. The population of the kingdom, which stood at only 3,000,000 in 1849, had advanced to over 5,000,000 by January 1900. In the provinces of North and South Holland the population has indeed almost doubled in half a century. The population of Amsterdam, The Hague, and Utrecht more than doubled, whilst that of Rotterdam shot up from 90,000 to 318,000. In 1850, 30,396 depositors had £317,580 in the private savings banks; in 1898 their number had increased to 361,509, and their claims to £6,512,000, notwithstanding the competition of the post office savings bank, which had, in 1898, 693,228 depositors, with a balance to their credit of £5,834,330. The imports for consumption, which were valued at £15,052,012 in 1849, had grown to £136,241,666 in 1896; the exports having increased in the same period from £10,634,128 to £111,708,333. The spending powers of the nation naturally kept pace with these increases, and the total budget expenses, which were £5,803,678 in 1850, had grown in 1897 to £11,560,737. It is true that the cessation of yearly contributions from the Dutch Indian revenues since 1878, and the constant enormous outlays for railways, canals, other public works, education, &c., caused in later years a material increase in the national debt, which stood at over £83,300,000 in 1898, but this increase was more than balanced by rapid decreases in the course of years. These aggregate about £91,660,000, whereas the increases were only £80,500,000; while by the repeated conversions, rendered possible by the steady rise in national credit, the annual debt charges were considerably lessened. On the other hand, it should be borne in mind that the national assets had been enormously strengthened since 1850, no less than £20,830,000 having been invested in the state railways alone by 1897, besides large investments in canals, the total length of which reached nearly 3000 English miles in 1898, and was constantly increasing. Among the greatest canals was the North Sea Canal at Amsterdam, originally constructed by a private company, but taken over in 1882 by the State. The dues were abolished in 1890, and this waterway considerably improved in 1896. Next in importance is the new waterway between Rotterdam and the German Ocean, which was completed in 1872, but has been improved since, allowing the largest ocean vessels to enter the Meuse, and making Rotterdam one of the greatest Continental ports. A further comparison of the State budgets for 1849 and 1897 shows that the advance was as marked in matters intellectual as in the material departments of national life. Thus education expenses in 1901 absorbed £833,000, against £43,500 fifty years before; the postal and telegraph services as much again, against £39,100 in 1849; in 1898, £2,000,000 was spent for public works and industries, against barely £166,000 in 1849; £70,450 for arts and science, against £9655 in 1849; and £115,700 for the colonies, which fifty years before yielded a revenue and cost nothing. Yet, by this immense material improvement in every department the burghers were at the end of the 19th century better able to pay £8,833,000 of taxes than those of 1849 to pay half that amount; their wealth had enormously grown, and the bulk of the national debt was held in Holland. Two principal conditions accompanied and dominated the great progress of these fifty years—the uninterrupted maintenance of peace, and the upholding of the principles of free trade, in which the Low Countries stood absolutely alone on the Continent of Europe.

For literature concerning this period of Dutch political history, see also the *Staatsalmanak* (official annual), the *Annual Register*, and similar publications in Holland and England; Motley's *Correspondence* (2 vols.); Henry Reeve's *Memoirs* (2 vols.); Earl of Malmesbury, *Memoirs of an Ex-Minister* (1884, 2 vols.); *Bismarck, the Man and the Statesman* (English translation, 1898, 2 vols.); *Les Pays Bas*, a sumptuous and full compendium of the Netherlands, privately printed and distributed by the Dutch Press Club of Amsterdam upon the occasion of Queen Wilhelmina's enthronement in 1898. There were also at that time numerous other publications of a similar character, mainly in the Dutch language, the principal among them being, perhaps, *Eene halve Eeuw* ("Half a Century," in 2 vols.), a comprehensive survey of modern Holland, historical, political, commercial, industrial, artistic, and literary, published at Amsterdam. (H. Ti.)

Recent Dutch Literature.

The recent literature of Holland presents the interesting phenomenon of an æsthetic revolution, carefully and cleverly planned, crowned with unanticipated success, and dying away in a languor encouraged by the complete absence of organized resistance. It would perhaps be difficult to point to another European example so well defined of the vicissitudes which keep the history of literature varied and fresh. For the thirty or forty years preceding 1880 the course of *belles-lettres* in Holland was smooth and even sluggish. The Dutch writers had slipped into a conventionality of treatment and a strict limitation of form from which even the most striking talents among them could scarcely escape. At the period of which we are about to speak, the most eminent authors of this early period were ready to pass away, and they appeared to be preparing no successors to take their place. The greatest humourist of Holland, Nicolaas Beets (born 1814) (*q.v.*), had drawn his works together. The most interesting novelist, Mrs Gertrude Bosboom-Toussaint (1812–1886) (*q.v.*), had in her last psychological stories shown an unexpected sympathy with new ideas. A very remarkable genius, of whom we write elsewhere, was Edward Douwes Dekker, "Multatuli" (1826–1887). The two other leading Dutch men of letters were critics, Conrad Busken-Huet (1826–1886) (*q.v.*) and Carel Vosmaer (1826–1888) (*q.v.*). In Huet the principles of the 1840–80 period were summed up; he had been during all those years the fearless and trusty watchdog of Dutch letters, as he understood them. He lived just long enough to become aware that a revolution was approaching, not to comprehend its character; but his accomplished fidelity to literary principle and his wide knowledge have been honoured even by the most bitter of the younger school. Vosmaer, although in certain directions more sympathetic than Huet, and himself an innovator, has not escaped so easily, because he has been charged with want of courage in accepting what he knew to be inevitable. We have now, however, mentioned the leaders of the old guard, and must proceed to sketch the course of the movement which replaced them.

In November 1881 there died a youth named Jacques Perk (1860–1881), who had done no more than publish a few sonnets in the *Spectator*, a journal published by Vosmaer. He was no sooner dead, however, than his posthumous poems, and in particular a cycle of sonnets called *Mathilde*, were published (1882), and awakened extraordinary emotion. Perk had rejected all the formulas of rhetorical poetry, and had broken up the conventional rhythms. There had been heard no music like his in Holland for two hundred years. A group of young men, united in a sort of esoteric adoration of the memory of Perk, collected around his name. They joined to their band a man somewhat older than themselves, Marcellus Emants (born 1848), who had come forward in 1879 with a symbolical poem called *Lilith*, which had been stigmatized as audacious and meaningless: encouraged by the admiration of his juniors, Emants published in 1881 a treatise on Young Holland, in which the first open attack was made on the old school. The next appearance was that of Willem Kloos (born 1857), who had been the editor and intimate friend of Perk, and who now undertook to

lead the army of rebellion. His violent attacks on recognized authority in æsthetics began in 1882, and created a considerable scandal. For some time, however, the new poets and critics found a great difficulty in being heard, since all the channels of periodical literature were closed to them. But in 1883 Emants expressed his intellectual aspirations in his *Twilight of the Gods*, and in 1884 the young school founded a review, *De Nieuwe Gids*, which was able to offer a direct challenge to *De Gids*, the ultra-respectable Dutch quarterly. In this year a new element was introduced: hitherto the influences of the young Dutch poetry had chiefly come from England; they were those of Shelley, Mrs Browning, the Rossettis. In 1884 Frans Netscher began to imitate with avidity the French naturalists. For some time, then, the new Dutch literature became a sort of mixture of Shelley and Zola, very violent, heady, and bewildering. In 1885 the *Persephone* of Albert Verwey and the *Hovering Butterflies* of Pol de Mont (born 1859) introduced two lyrical poets of real merit to Holland; Emants published his *Gondakker's Illusions*. This was the great flowering moment of the new school. It was at this juncture that the principal recent writer of Holland, Louis Couperus (born 1863), made his first definite appearance. Born in The Hague, the opening years of his boyhood were spent in Java, and he had preserved in all his nature a certain tropical magnificence. In 1884 a little volume of lyrics, and in 1886 the more important *Orchids*, showed in Couperus a poet whose sympathies were at first entirely with the new school. But he was destined to be a novelist, and his earliest story, *Eline Vere* (1889), already took him out of the ranks of his contemporaries. In 1890 he published *Destiny* (known as *Footsteps of Fate* in the English version), and in 1892 *Ecstasy*. This was followed in 1894 by *Majesty*, in 1896 by *World-wide Peace*, in 1898 by *Metamorphosis*, a delicate study of character, in 1899 by *Fidessa*, and in 1901 by *Quiet Force*. Of all these later books by Couperus, it is perhaps *Ecstasy* in which the peculiar quality of his work is seen at present to the greatest advantage. This is an extreme sensitiveness to psychological phenomena, expressed in terms of singular delicacy and beauty. The talent of Couperus is like a rich but simple tropical flower laden with colour and odour. He separated himself, as he developed, from the more fanatical members of the group, and addressed himself to the wider public. Another writer, of a totally different class, resembling Couperus only in his defiance of the ruling system of æsthetics, is the prominent Ultramontane politician, E. J. A. M. Schaepmann (born 1844), whose poem of *Aja Sofia* originally appeared in 1886. Recent novelists of some polemical vigour are H. Borel and van Hulzen. A very delightful talent was revealed by Frederick van Eeden in *Little Johnny* (1887), a prose fairy-tale; in *Ellen* (1890), a cycle of mysterious and musical elegies; and in *From the Cold Pools of Death* (1901), a very melancholy novel. Another poet of less refinement of spirit, but even greater sumptuousness of form, appeared in Helène Swarth-Lapidoth (born 1859), whose *Pictures and Voices* belongs to 1887. In that year also, in which Dutch literature reached its height of fecundity, was published the powerful and scandalous naturalistic novel, *A Love*, by L. van Deyssel, who had hitherto been known chiefly as a most uncompromising critic. Since 1887 the condition of modern Dutch literature has been comparatively stationary, and even within the last decade of the 19th century definitely declining. In 1889, it is true, a new poet, Herman Gorter, made his appearance with a volume of strange verses called *May*, eccentric both in prosody and in treatment. He held his own without any marked advance towards lucidity or variety. Since the recognition of Gorter, however, no really remarkable talent has made itself prominent in Dutch poetry, unless we except P. C. Boutens, whose *Verses* in 1898 were received with great respect. Willem Kloos, still the acute and somewhat turbulent leader of the school, collected his poems in 1894 and his critical essays in 1896. L. van Deyssel, though an effective reviewer, continued to lack the erudition which years should have brought to him. Among the pure poets, the Fleming, Pol de Mont, with his *Claribella* (1893) and his *Iris* (1894), possibly showed the most definite advance. Gorter remained tenebrous, Helène Swarth-Lapidoth still gorgeous; the others, with the exception of Couperus, showed symptoms of sinking into silence. The entire school, now that the struggle for recognition is over, and its members are accepted as little classics and the tyrants of taste, rests on its triumphs and seems to limit itself to a repetition of its old experiments. In drama almost the only notable products are those of De Koo, whose *Tobias Bolderman* (1900) and *Vier Ton* (1901) are effective comedies. Dutch literature presented features of remarkable interest between 1882 and 1888, but since that time the general heightening of the average of merit, the abandonment of the old dry conventions, and a recognition of the artistic value of words and forms, are more evident to a foreign observer than any very important single expression of the national genius in literary art. An exception should be made in favour of the powerful peasant-stories of Steijn Streuvels, a young baker by trade, whose *Summer Land* (1901) is a most promising production.

Interesting observations on the development of the new school in Dutch literature will be found in Willem Kloos, *Veertien Jaar Literatuur-Geschiedenis*, 2 vols., 1896, and in L. van Deyssel, *Verzamelde Opstelen*, 4 vols., 1890–97. (E. G.)

Holland, NORTH and SOUTH, two adjoining provinces of the Netherlands, between the Zuyder Zee, the most southerly branch of the Meuse, and the North Sea. The surface is mostly beneath sea-level, but is protected by dykes; the soil is fertile and diligently cultivated. The chief towns in North Holland are Amsterdam, Haarlem, Alkmaar, Heeder, Hoorn, and Zaandam. In South Holland the principal towns are Rotterdam, The Hague, Leyden, Delft, Schiedam, and Gouda. The Hook of Holland, the new approach to Central Europe from Harwich, occupies almost the extreme south-western point of a promontory of South Holland. (For statistics see HOLLAND: *Geography*.)

Holland, a city of Ottawa county, Michigan, U.S.A., on a navigable inlet at the mouth of the Black River, and on the Chicago and West Michigan Railway, at an altitude of 609 feet. It is a summer resort, and the seat of Hope College, founded in 1865, which in 1899 had 15 instructors and 214 students, of whom 27 were women. Population (1880), 2620; (1890), 3945; (1900), 7790, of whom 2075 were foreign-born.

Holland, Josiah Gilbert (1819–1881), American author and editor, was born in Belchertown, Massachusetts, 24th July 1819. He studied medicine in the Berkshire Medical College (no longer in existence) at Pittsfield, in the same state; was for a brief period superintendent of schools in Vicksburg, Mississippi; but in 1849 became one of the editors and owners of the Springfield (Massachusetts) *Republican*, with which he retained his connexion for seventeen years. In 1870, having resigned his position upon that journal and travelled in Europe, he removed to New York and established *Scribner's Monthly* (the title of which was later changed to *The Century*) by developing an earlier magazine of more limited scope, and gave it a character of its own, in which were combined readableness, literary tone, and social helpfulness. Dr Holland's numerous books, partly reprints

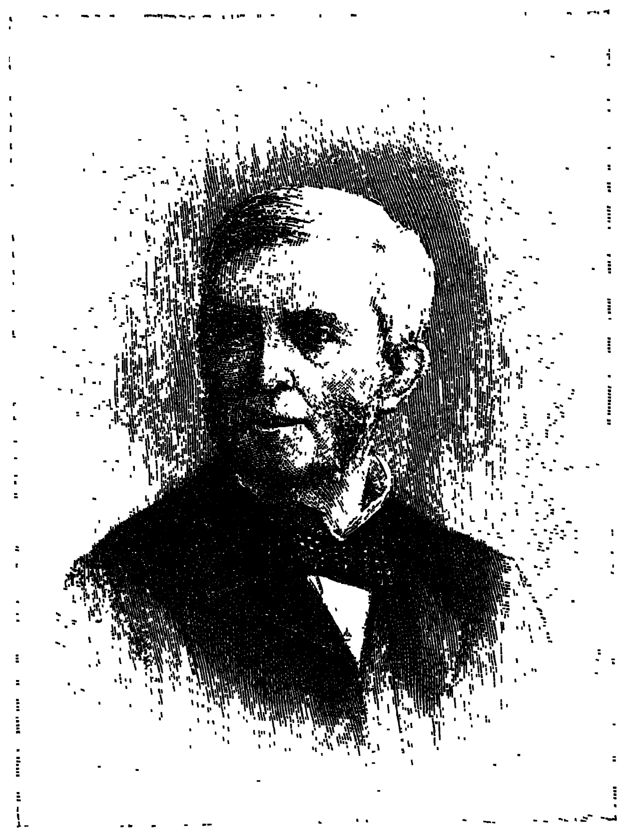
of his contributions to the *Republican* and *Scribner's Monthly*, long enjoyed a wide popularity. These writings fall into four classes: history and biography, represented by a *Life of Abraham Lincoln* (1865), of which more than 100,000 copies were sold soon after the assassination of the President; fiction, of which *Miss Gilbert's Career* (1860) and *The Story of Sevenoaks* (1875) remain faithful pictures of village life in Eastern America; poetry, of which the easily-moving narratives, *Bitter-Sweet* (1858) and *Kathrina, Her Life and Mine* (1867), were widely read; and a series of homely and suggestive essays on the art of living, of which the most characteristic were *Letters to Young People, Single and Married* (1858), *Gold Foil, hammered from Popular Proverbs* (1859), *Letters to the Joneses* (1863), and *Every-Day Topics* (two series, 1876 and 1882). While a resident of New York, where he died 12th October 1881, Dr Holland identified himself with measures for good government and school reform, being at one time president of the Board of Education.

Holloway, Thomas (1800–1883), English patent-medicine vendor and philanthropist, was born at Devonport, 22nd September 1800, of humble parents. Until his twenty-eighth year he lived at Penzance, where he assisted his mother and brother in the baker's shop which his father, once a warrant officer in a militia regiment, had left them at his death. On coming to London he made the acquaintance of Felix Albinolo, an Italian, from whom he obtained the recipe for the ointment which was to carry his name all over the world. The secret of his enormous success in business was due almost entirely to advertisement, in the efficacy of which he had great faith. He soon added the sale of pills to that of the ointment, and began to devote the larger part of his profits to advertising. Holloway's first newspaper announcement appeared on 15th October 1837, and in 1842 his yearly expenses for publicity had reached the sum of £5000; this expenditure went on steadily increasing as his sales increased, until it had reached the figure of £50,000 per annum at the time of his death. It is, however, chiefly by the two princely foundations—the Sanatorium and the College for Women, endowed by Holloway towards the close of his life—that his name will be perpetuated, more than a million sterling having been set apart by him for the erection and permanent endowment of these institutions. In the deed of gift of the college the founder credited his wife, who died in 1875, with the advice and counsel that led him to provide what he hoped might ultimately become the nucleus of a university for women. The Holloway Sanatorium was the first to be opened, in June 1885, eighteen months after the founder's death. It is an asylum for patients of the middle class, of both sexes, afflicted with mental disorders, and is intended to be to a considerable extent self-supporting, a moderate charge being made for the reception of inmates whose families can afford to pay. The institution and the surrounding grounds include some forty acres situated at St Anne's Heath, near Virginia Water, the building containing about 600 rooms, disposed on four floors, and capable of accommodating about 250 patients. All the structural and decorative features are on a grand scale and of a highly artistic nature, devised with the purpose of giving wearied brain-workers an opportunity of recovering their faculties. The Royal Holloway College for Women at Mount Lee, Egham, was opened by Queen Victoria in July 1886. The building, surrounded by grounds 95 acres in extent, stands on a picturesque wooded slope, commanding a splendid view; it contains nearly a thousand rooms, and has accommodation for 250 students and an ample staff. The recreation hall is an art gallery, containing pictures which cost upwards of £90,000. Like the sanatorium, it was furnished throughout in the most sumptuous manner, and, also like that institution, it is mainly self-supporting. It is unsectarian, the management being vested in a representative body of governors. The philanthropic and somewhat eccentric donor (he had an unconcealed prejudice against doctors, lawyers, and parsons) died of congestion of the lungs on 26th December 1883.

Holmes, Oliver Wendell (1809–1894), American writer and physician, was born 29th August 1809 at Cambridge, Massachusetts. His father, Abiel Holmes, was a Calvinist clergyman, the writer of a useful history, *Annals of America*, and of much very dull poetry. His mother (the second wife of Abiel) was Sarah Wendell, of a distinguished New York family. Through her Dr Holmes was descended from Governors Thomas Dudley and Simon Bradstreet of Massachusetts, and from her he derived his cheerfulness and vivacity, his sympathetic humour and wit. From Phillips Academy he entered Harvard College in the "famous class of '29," made further illustrious by the charming lyrics which he wrote for the anniversary dinners from 1851 to 1889, closing with the touching "After the Curfew." After graduation he studied law perfunctorily for a year and dabbled in literature, winning the public ear by a spirited lyric called forth by the order to destroy the old frigate *Constitution*. These verses were sung all over the land, and induced the Navy Department to revoke its order and save the old ship. Turning next to medicine, and convinced by a brief experience in Boston that he liked it, he went to Paris in March 1833. He studied industriously under Louis and other famous physicians and surgeons in France, and in his vacations visited the Low Countries, England, Scotland, and Italy. Returning to Boston at the close of 1835, filled with a high professional ambition, he sought practice, but achieved only moderate success. Social, brilliant in conversation, and a writer of gay little poems, he seemed to the grave Bostonians not sufficiently serious. He won prizes, however, for professional papers, and lectured on anatomy at Dartmouth College. He wrote two papers on homœopathy, which he attacked with trenchant wit; also a valuable paper on the malarial fevers of New England. In 1843 he published his essay on the *Contagiousness of Puerperal Fever*, which stirred up a fierce controversy and brought upon him bitter personal abuse; but he maintained his position with dignity, temper, and judgment; and in time he was honoured as the discoverer of a beneficent truth. The volume of his medical essays holds some of his most sparkling wit, his shrewdest observation, his kindliest humanity. In 1840 he married Amelia Lee Jackson, daughter of the Hon. Charles Jackson, Associate Justice of the Supreme Judicial Court of Massachusetts, a lady of rare charm alike of mind and character. She died in the winter of 1887–88. Their first-born child, Oliver Wendell Holmes, afterwards became Chief Justice of that same bench on which his grandfather sat. In 1847 Dr Holmes was appointed Professor of Anatomy and Physiology in the Medical School of Harvard University, the duties involving the giving of instruction also in kindred departments, so that, as he said, he occupied "not a chair, but a settee in the school." He delivered the anatomical lectures until November 1882, and in later years these were his only link with the medical profession. They were fresh, witty, and lively; and the students were sent to him at the end of the day, when they were fagged, because he alone could keep them awake. In later years he made few finished contributions to medical knowledge;

his eager and impetuous temperament caused him to leave more patient investigators to push to ultimate results the suggestions thrown out by his fertile and imaginative mind.

In 1836, being in that year the Phi Beta Kappa poet at Harvard University, he published his first volume of poems, which afterwards reached a second edition. Among these earlier lyrics was "The Last Leaf," one of the most delicate combinations of pathos and humour in literature. His collected poetry fills three volumes. In 1856–57 a Boston publishing house (Phillips, Sampson, and Co.) invited James Russell Lowell to edit a new magazine, which he agreed to do on condition that he could secure the assistance of Dr Holmes. By this urgent invitation the Doctor was equally surprised and flattered, for heretofore he had stood rather outside the literary coterie of Cambridge and Boston. He accepted with pleasure, and at once threw himself into the enterprise with zeal. He christened it *The Atlantic Monthly;* and, as Mr Howells afterwards said, he "not only named but made" it, for in each number of its first volume there appeared one of the papers of the *Autocrat of the Breakfast Table.* The opening of the *Autocrat*—"I was just going to say when I was interrupted"—is explained by the fact that in the old *New England Magazine* (1831 to 1833) the Doctor had published two *Autocrat* papers, which, by his wish, have never been reprinted. In the commercial panic of 1857 the new magazine would inevitably have failed had it not been for these fascinating essays. Their originality of conception, their wit and humour, their suggestions of what then seemed bold ideas, and their expression of New Englandism, all combined to make them so popular that the most harassed merchant in that gloomy winter purchased them as a dose of cheering medicine. Thus Dr Holmes made *The Atlantic Monthly*, which in return made him. A success so immediate and so splendid settled the rest of his career; he ceased to be a physician, and became an author. These twelve papers were immediately (1858) published as a volume. No sooner was the *Autocrat* silent than the *Professor* (1859) succeeded him at the breakfast table. The *Professor* was preferred by more thoughtful readers, though it has hardly been so widely popular as the *Autocrat.* Its theology, which seemed in those days audacious, frightened many of the strict and old-fashioned religionists of New England, though to-day it seems mild enough. Twelve years later, in 1871, the Landlady had another boarder, who took the vacant chair—the *Poet* (published 1872). But here Holmes fell a little short. In these three books, especially in the *Autocrat* and the *Professor*, the Doctor wrote as he talked at many a dinner table in Boston, but less well. The animation and clash of talk roused him. The dinners of the Saturday Club are among Boston's proudest traditions, as they were the chief pleasure of Dr Holmes's life. There he met Emerson, Longfellow, Whittier, Lowell, Sumner, Agassiz, Motley, and many other charming talkers, and among them all he was admitted to be the best.



OLIVER WENDELL HOLMES.
(From a photograph by Elliott and Fry, London.)

There were characters and incidents, but hardly a story, in the *Autocrat* and the *Professor.* Holmes had an ambition for more sustained work, and in 1861 his novel, *Elsie Venner*, at first called *The Professor's Story*, was published. The book was illuminated throughout by admirable pictures of character and society in the typical New England town. But the rattlesnake element was unduly extravagant, and in other respects the book was open to criticism as a work of art. It was written with the same purpose which informed the greatest part of the Doctor's literary work, and which had already been scented and nervously condemned by the religious world. By heredity the Doctor was a theologian; no other topic enchained him more than did the stern and merciless dogmas of his Calvinist forefathers. His humanity revolted against them, his reason condemned them, and he set himself to their destruction as his task in literature. The religious world of his time was still so largely under the control of old ideas that he was assailed as a freethinker and a subverter of Christianity; though before his death opinions had so changed that the bitterness of the attacks upon him seemed incredible even to some of those who had most vehemently made them. None the less, undaunted and profoundly earnest, he returned, six years later, to the same line of thought in his second novel, *The Guardian Angel* (published 1867). This, though less well known than *Elsie Venner*, is in many respects better. No more lifelike and charming picture of the society of the New England country town of the middle third of the 19th century has ever been drawn, and every page sparkles with wit and humour. In 1884 and 1885 it was followed, still in the same line, by *A Mortal Antipathy*, a production inferior to its predecessors.

Holmes generally held himself aloof from politics, and from those "causes" of temperance, abolition, and woman's rights which enthralled most of his contemporaries in New England. The Civil War, however, aroused him for the time; finding him first a strenuous Unionist, it quickly converted him into an ardent advocate of emancipation. His interest was enhanced by the career of his elder son, who was three times severely wounded, and finally rose to the rank of lieutenant-colonel in the Northern army. He wrote some ringing war lyrics, and in 1863 delivered the Fourth of July oration in Boston, which showed a masterly appreciation of the stirring public questions of

the day. In 1878 Dr Holmes wrote a memoir of the historian John Lothrop Motley, an affectionate tribute to one who had been his dear friend. In 1884 he contributed the life of Emerson to the American Men of Letters Series. He admired the "Sage of Concord," but was not quite in intellectual sympathy with him. Both were Liberals in thought, but in widely different ways. But in spite of this handicap, the volume proved very popular. In 1888 he began the papers which he happily christened *Over the Tea Cups.* As a *tour de force* on the part of a man of nearly fourscore years they are very remarkable.

After his return from Paris in 1835 Dr Holmes lived in Boston, with summer sojournings at Pittsfield and Beverly Farms, and occasional trips to neighbouring cities, until 1886. He then undertook a four months' journey in Europe, and in England had a sort of triumphal progress. On his return he wrote *Our Hundred Days in Europe* (1887), a courteous recognition of the hospitality and praise which had been accorded to him. During this visit Cambridge University made him Doctor of Letters, Edinburgh University made him Doctor of Laws, and Oxford University made him Doctor of Civil Law. Already, in 1880, Harvard University had made him Doctor of Laws. He died on 7th October 1894, and was buried from King's Chapel, Boston, in the cemetery of Mount Auburn.

(J. T. Mo.)

Holmfirth, a town in the Holmfirth parliamentary division of Yorkshire, England, on the Holme and Ribble, 6 miles south of Huddersfield and on the Lancashire and Yorkshire Railway. There are a town-hall, a drill-hall, and a technical institute, three churches, and several chapels. Woollen manufactures form the principal industry. In the neighbourhood there is picturesque scenery. Area (urban district), 7094 acres. Population (1901), 8976.

Holtzendorff, Joachim Wilhelm Franz Philipp von (1829–1889), German jurist, born at Vietmannsdorf, in the Mark of Brandenburg, on 14th October 1829, was descended from a family of the old nobility. He was educated at Berlin and at Pforta, afterwards studying law at the universities of Bonn, Heidelberg, and Berlin. He saw the struggles of 1848 with youthful enthusiasm, and remained for the rest of his life a strong advocate of political liberty. In 1852 he graduated LL.D. at Berlin; in 1857 he became a *privat-docent*, and in 1860 he was nominated a professor extraordinary. The predominant party in Prussia regarded his political opinions with mistrust, and he was not offered an ordinary professorship until February 1873, after he had decided to accept a chair at the university of Munich. At Munich he passed the last nineteen years of his life. During the thirty years that he was professor he successively taught several branches of jurisprudence, but he was chiefly distinguished as an authority on criminal and international law. He was especially well fitted for organizing collective work, and he has associated his name with a series of publications of the first value. While acting as editor he often reserved for himself, among the independent monographs of which the work was composed, only those on subjects distasteful to his collaborators on account of their obscurity or lack of importance. Among the compilations which he superintended may be mentioned his *Encyclopädie der Rechtswissenschaft* (Leipzig, 1870–71, 2 vols.; fifth edition, 1890), his *Handbuch des deutschen Strafrechts* (Berlin, 1871–77, 4 vols.), and his *Handbuch des Völkerrechts auf Grundlage Europäischer Staatspraxis* (Berlin, 1885–90, 4 vols.). Among his many independent works may be mentioned: *Das irische Gefängnisssystem* (Leipzig, 1859), *Französische Rechtszustände* (Leipzig, 1859), *Die Deportation als Strafmittel* (Leipzig, 1859), *Die Kürzungsfähigkeit der Freiheitsstrafen* (Leipzig, 1861), *Die Reform der Staatsanwaltschaft in Deutschland* (Berlin, 1864), *Die Umgestaltung der Staatsanwaltschaft* (Berlin, 1865), *Die Principien der Politik* (Berlin, 1869), *Das Verbrechen des Mordes und die Todesstrafe* (Berlin, 1875), *Rumäniens Uferrechte an der Donau* (Leipzig, 1883; French edition, 1884). He also edited or assisted in editing a number of periodical publications on legal subjects. From 1866 to the time of his death he was associated with Rudolf Ludwig Carl Virchow in editing *Sammlung gemeinverständlicher wissenschaftlicher Vorträge* (Berlin). Von Holtzendorff died at Munich on 4th February 1889. (E. I. C.)

Holyhead, a seaport and naval station on the north-east shore of an island of the same name lying off the west coast, and part of the county, of Anglesea, Wales. In 1885 its parliamentary representation was merged in that of the county. There are a hospital, a sailors' home, and almshouses. Area of urban district, 732 acres. Population (1881), 8680; (1901), 10,072. The island is about 7½ miles long, with a breadth varying from 4 miles to half a mile. On the north-west is the "head," a serpentine mass 719 feet high, and off this are two rocks, the North and South Stacks, with lighthouses.

Holyoake, George Jacob (1817–——), English secularist and co-operator, was born at Birmingham, 13th April 1817. At an early age he became an Owenite lecturer, and in 1841 was the last person convicted for blasphemy in a public lecture, though this had no theological character and the incriminating words were merely a reply to a question addressed to him from the body of the meeting. He nevertheless underwent six months' imprisonment, and upon his release invented the inoffensive term "secularism" as descriptive of his opinions, and established *The Reasoner* in their support. He was also the last person indicted for publishing an unstamped newspaper, but the prosecution dropped upon the repeal of the tax. His later years were chiefly devoted to the promotion of the co-operative movement among the working classes. He wrote the history of the Rochdale Pioneers (1857), the *History of Co-operation in England* (1875), and *The Co-operative Movement of To-day* (1891). He also published (1892) his autobiography, under the title of *Sixty Years of an Agitator's Life.*

Holyoke, a city of Hampden county, Massachusetts, U.S.A., on the west bank of the river Connecticut, 8 miles north of Springfield, at an altitude of 114 feet. The plan of the city is regular and divided into seven wards. It derives its water supply by gravity from lakes in the adjacent hills. It is on the Boston and Maine, and the New York, New Haven, and Hartford railways. Hadley Falls, in the Connecticut, have a fall of about 60 feet, and furnish valuable water-power, the utilization of which has made Holyoke an important manufacturing city. In 1900 it had 433 manufacturing establishments, employing 13,454 hands, and producing goods valued at $26,283,964. Of these, paper and wood pulp were the most important products, having a value of $8,109,485. Cotton goods to the value of $3,764,848, and woollen goods valued at $1,424,897, were also produced. The assessed valuation of real and personal property in 1900 was $39,735,580; the net debt of the city was $1,739,868; and the rate of taxation was $16·40 per $1000. Population (1880), 21,915; (1890), 35,637; (1900), 45,712, of whom 18,921 were foreign-born and 40 negroes. The death-rate in 1890 was 22·8; in 1900 it was 17·9.

Homburg vor der Höhe, a famous watering-place of Prussia, in the province of Hesse-Nassau, at the south-east foot of the Taunus Mountains, 12 miles by rail north-north-west of Frankfort-on-Main, frequented by more than 10,000 visitors annually. In 1897 a Russian (Orthodox Greek) chapel was built, and in 1892 a marble bust of the Emperor Frederick III. was unveiled. A new bath-house was built in 1887–90, and a new salt spring bored in 1898. There is also a new Roman Catholic church (1895). In 1900 the ancient Roman castle of the Saalburg was converted into an imperial museum. Population (1885), 8857; (1900), 9636.

Homer, Winslow (1836–——), American painter, was born in Boston, U.S.A., 24th February 1836. At the age of nineteen he was apprenticed to a lithographer. Two years later he opened a studio in Boston, and devoted much of his time to making drawings for wood-engravers. In 1859 he removed to New York, where he studied in the night-school of the National Academy of Design. During the American Civil War he was with the troops at the front, and contributed sketches to *Harper's Weekly*. The war also furnished him with the subjects for the first two pictures which he exhibited (1863), one of which was "Home, Sweet Home." His "Prisoners from the Front"—perhaps his most generally popular picture—was exhibited in New York in 1865, and also in Paris in 1867, where he was spending the year in study. Among his other paintings in oil are "Snap the Whip" (which was exhibited at the Philadelphia Centennial Exposition of 1876, and, in company with "The Country Schoolroom," at the Paris Salon the following year), "Eating Water-melon," "The Cotton Pickers," "Visit from the Old Mistress, Sunday Morning," "The Life-Line," and "The Coming of the Gale." His genius, however, has perhaps shown better in his works in water-colour, among which are his marine studies painted at Gloucester, Mass., and his "Inside the Bar," "The Voice from the Cliffs" (pictures of English fisherwomen), "Tynemouth," "Wrecking of a Vessel," and "Lost on the Grand Banks." His work, which principally consists of *genre* pictures, is characterized by strength, rugged directness, and unmistakable freshness and originality, rather than by technical excellence, grace of line, or beauty of colour. He was little affected by European influences. His types and scenes, apart from his few English pictures, are distinctly American—soldiers in blue, New England children, negroes in the land of cotton, Gloucester fishermen and stormy Atlantic seas. Besides being a member of the Society of Painters in Water-colour, New York, he was elected in 1864 an associate and the following year a member of the National Academy of Design.

Homestead, a borough of Allegheny county, Pennsylvania, U.S.A., on the river Monongahela, 8 miles south-east of Pittsburg, at an altitude of 759 feet. It is on the Pennsylvania and the Pittsburg and Lake Erie Railways. It is known chiefly as the site of the great iron and steel works of the Carnegie Company, and as the scene, in 1892, of a serious labour strike, which was quelled only by the calling out of the National Guard of the state. Population (1880), 592; (1890), 7911; (1900), 12,554, of whom 3604 were foreign-born and 640 were negroes.

Homœopathy.—The system of therapeutics which bears the name of Homœopathy is based upon the law *similia similibus curentur*, the originator of which was Hahnemann, a native of Meissen in Germany, who discovered his new principle while he was experimenting with cinchona bark in 1790, and announced it in 1796. The essential tenets of homœopathy are that the cure of disease is effected by drugs that are capable of producing in a healthy individual symptoms similar to those of the disease to be treated, and that to ascertain the curative virtues of any drug it must be "proved" upon healthy persons—that is, taken by individuals of both sexes in a state of health in gradually increasing doses. The manifestations of drug action thus produced are carefully recorded, and this record of "drug-diseases," after being verified by repetition on many "provers," constitutes the distinguishing feature of the homœopathic materia medica, which, while it embraces the sources, preparation, and uses of drugs as known to the orthodox pharmacopœia, contains, in addition, the various "provings" obtained in the manner above described. Within the past few years an interesting controversy has been carried on between the members of the homœopathic school as to the proper construction of the Latin motto which constitutes its acknowledged basis. For many years the verb at the conclusion of the sentence was used in the indicative mood, *curantur*, thus making the sentence a positive one. After extended research it has been discovered that Hahnemann himself never employed the word *curantur* as descriptive of his law of cure, but always wrote *curentur*, which greatly modifies the meaning of the phrase. If the subjunctive mood be used, the motto reads, "Let similars be treated by similars," or "Similars should be treated by similars." The reading *similia similibus curentur* was officially adopted as the correct reading of the sentence by the American Institute of Homœopathy at its session held in Atlantic City, N.J., 20th June 1899; and the words are so inscribed on the monument erected to the memory of Hahnemann and unveiled in Washington, D.C., on 23rd June 1900, and also are those carved upon the tomb of Hahnemann in Père-la-Chaise, Paris.

Besides the promulgation of the doctrine of similars, Hahnemann also enunciated a theory to account for the origin of all chronic diseases, which he asserted were derived either directly or remotely from psora (the itch), syphilis (venereal disease), or sycosis (fig-wart disease). This doctrine, although at first adopted by some of the enthusiastic followers of Hahnemann, was almost immediately discarded by very many who had a firm belief in his law of cure. In the light of advancing science such theories are entirely untenable, and it was unfortunate for the system of medicine which he founded that Hahnemann should have promulgated such a hypothesis. It served as a target for the shafts of ridicule showered upon the system by those who were its opponents, and even at the present time there still exists in the minds of many misinformed persons the conviction that homœopathy is a system of medicine that bases the origin of all chronic disease on the itch or on syphilis or fig-warts.

Another peculiar feature of homœopathy is its posology or theory of dose. It may be asserted that homœopathic posology has nothing more to do with the original law of cure than the psora (itch) theory has, and that it was one of the later creations of Hahnemann's mind. Most homœopathists believe more or less in the action of minute doses of medicine, but it must not be considered as an integral part of the system. The dose is the corollary, not the principle. Yet in the minds of many, infinitesimal doses of medicine stand for homœopathy itself, the real law of cure being completely put into the background. The question of dose has also divided the members of the homœopathic school into bitter factions, and is therefore a matter for careful consideration. Many employ low potencies,[1] *i.e.*, mother tinctures, first,

[1] Two methods of preparing medicines are recognized, one on the decimal, the other on the centesimal scale. The pure tinctures are denominated "mother tinctures," and represented by the Greek ϕ. To make a first decimal dilution or first decimal trituration, 10 drops of

second, sixth dilutions, &c., while others use hundred-thousandths and millionths.

Some homœopathists of the present day still believe with Hahnemann that, even after the material medicinal particles of a drug have been subdivided to the fullest extent, the continuation of the dynamization or trituration or succussion develops a spiritual curative agency, and that the higher the potency, the more subtle and more powerful is the curative action. Hahnemann says (*Organon*, third American edition, p. 101), "It is only by means of the spiritual influence of a morbific agent that our spiritual vital power can be diseased, and in like manner only by the spiritual operation of medicine can health be restored." This is absolutely denied by others. Thus at the present time there exist two schools among the adherents of homœopathy. On the one hand there are the Hahnemannians, the "Purists" or "High Potency" men, who still profess to regard the *Organon* as their Bible, who believe in all the teachings of Hahnemann, who adhere in their prescriptions to the single dose, the single medicine, and the highest possible potency, and regard the doctrine of the spiritual dynamization acquired by trituration and succussion as indubitable. On the other side there are the "Rational" or "Low Potency" men, who believe in the universality of the law of cure, but think that it cannot always be applied, on account of an imperfect materia medica and a lack of knowledge on the part of the physician. They believe that in many cases of severe and acute pain palliatives are required, and that they are free to use all the adjuvants at present known to science for the relief of suffering humanity—massage, balneology, electricity, hygiene, &c. The American Institute of Homœopathy, the national body of the United States, has adopted the following resolution and ordered it to be published conspicuously in each number of the *Transactions* of the society:—"A homœopathic physician is one who adds to his knowledge of medicine a special knowledge of homœopathic therapeutics. All that pertains to the great field of medical learning is his by tradition, by inheritance, by right."

The effect produced upon both the laity and the general profession of medicine by the introduction of homœopathy was salutary in many ways. It diminished the quantity of medicine that was formerly considered necessary for the eradication of disease, and thus revealed the fact that the *vis medicatrix naturæ* is often sufficient, with occasional and gentle assistance, to cure many diseases, especially those fevers that run a definite and regular course. In addition it prepared the medical mind for the reception of truths soon to be revealed by the aid of the microscope by Schwann, Pasteur, Chevreul, Davine, and Lister. The trend of the belief in the law *similia similibus curentur* is now forcibly shown by the rapidly increasing adoption of the serum therapy, which consists in the treatment of the most malignant diseases (diphtheria, lock-jaw, typhoid fever, tuberculosis, bubonic plague) by introducing into the system a modified form (similar) of those poisons that produce them in the healthy individual. Progressive physicians at the present time do not hesitate to acknowledge the homœopathic doctrine as true under certain conditions, their only objection to it being that it is "sectarian." It has been publicly announced that if the homœopathists would abolish the name "homœopathy," and remove it from their periodicals, colleges, hospitals, dispensaries, and asylums, they would be received within the fold of the regular profession. These conditions have been accepted by a few homœopathists who have become members of the most prominent medical association in the United States.

Homœopathy as it exists to-day can, in the opinion of its adherents, stand by itself, and its steady progress for a century in face of prolonged and determined opposition appears to its upholders to be evidence of its truth. There are still, indeed, in both schools of medical thought, men who stand fast by their old principles. There are homœopathists who can see nothing but evil in the practice of their brothers of the orthodox school, as there are allopathists who still regard homœopathy as a humbug and a sham. There are, however, liberal-minded men in both schools, who look upon the adoption of any safe and efficient method of curing disease as the birthright of the true physician, and who allow every man to prescribe for his patients as his conscience may dictate, and, provided he be educated in all the collateral branches of medical science, are ready to exchange views for the good of suffering humanity.

Great Britain.—Homœopathy is not rapidly extending in Great Britain, and its recognition has been slow. The first notice taken of the new system of therapeutics was by the Medical Society of London in 1826. In 1827 the physician of Prince Leopold of Saxe-Coburg, Dr Quin, who had previously studied homœopathy in Germany and practised it in Italy, came to England, and it was through his efforts that the system was introduced. Three other physicians, Dr Belluomini, Dr Romani, and Dr Tagliani, claimed priority, but careful research established Dr Quin's title. Quin was a successful man professionally and socially, and brought upon himself in a short time the anathema of the Royal College of Physicians. In 1844 Dr Henderson, professor of pathology in the University of Edinburgh, embraced the Hahnemannian system. A storm of opposition arose, and Professor J. Y. Simpson (the discoverer of chloroform anæsthesia) published a volume, with the alliterative title, *Homœopathy, its Tenets and Tendencies, Theoretical, Theological, and Therapeutical.* This brochure was answered by Professor Henderson, the title of his book being *Homœopathy Fairly Represented.* From 1827 to 1837 there were but a dozen practitioners of homœopathy in London, but during 1837 to 1847 the number increased to between seventy and eighty. In 1857 there were upwards of two hundred practitioners in the kingdom, with thirty-three institutions in which the law of similars was used as a basis of practice. In 1867 the increase was not so rapid, the number being 261. A society was formed about this period for "the protection of homœopathic practitioners and students," which proved of great value in binding the sect together. In 1870 congresses were established and annual meetings held, which have continued to the present time. In 1901 there were over three hundred homœopathic physicians in the British Isles, of whom between seventy and eighty were in London alone. There were seventy-nine chemists, of whom seventeen were located in London, and eighty-two towns and cities in the country contained from one to ten homœopathic practitioners each, together with many established chemists for dispensing homœopathic medicines. The British Homœopathic Medical Society, founded by Quin in 1844, is in a flourishing condition, having two hundred and eight members, thirty-four fellows, and thirty-one corresponding members in all portions of the world, including Australia, India, and Tasmania. The London Homœopathic Hospital was founded in 1850, and a few years afterwards moved to Great Ormond Street. During the cholera epidemic of 1854 the statistics of this hospital showed a mortality of 16·4 per cent., against 51·8 per cent. of other metropolitan charities. The London Homœopathic Hospital has a convalescent home under its management at Eastbourne. There are also dispensaries in Ealing and West Middlesex, Kensington, Notting Hill, and Bayswater. Similar institutions, all in a flourishing condition, are located in Bath, Birkenhead, Birmingham, Bootle, Bournemouth, Brighton, Bristol, Bromley, Cheltenham, Cheshire, Croydon, Dublin, Eastbourne, Edinburgh, Folkestone, Hastings and St Leonards, Ipswich, Leeds, Leicester, Liverpool, Newcastle, Northampton, Norwich, Oxford, Plymouth, Torquay, Tunbridge

the mother tincture, or 10 grains of a crude substance, are mixed with 90 drops of alcohol, or 90 grains of *saccharum lactis* (sugar of milk) respectively. The liquid is thoroughly shaken, or the powder carefully triturated, and the bottles containing them marked 1 X, meaning first decimal dilution or trituration. To make the 2 X potency, 10 drops or 10 grains of this first dilution or trituration are mixed with 90 drops of pure alcohol, or 90 grains of milk sugar, and are succussed or triturated as above described and marked 2 X dilution or trituration. This subdivision of particles may be continued to an indefinite degree. On the Hahnemannian or centesimal scale the medicines are prepared in the same manner, the difference being that 1 drop or grain is mixed with 99 drops or grains, to make the first centesimal, which is marked 1 c or 1 simply, and so on for the second and higher dilutions.

Wells, Weston-super-Mare. The journals now in existence are the *Homœopathic World*, the *Monthly Homœopathic Review*, the *London Homœopathic Hospital Reports*, and the *Journal of the British Homœopathic Society*. There are also several of lesser note. The *British Journal of Homœopathy* was first published in 1843, and was edited by Drs Drysdale, Russell, and Black. For many years it was the foremost homœopathic journal in the world. Its motto was *In certis unitas, in dubiis libertas, in omnibus charitas*. One reason why homœopathy has not advanced as rapidly in the British Isles as in America is said to be the discrimination exercised against it by the General Medical Council, and another is want of cohesion amongst the homœopaths themselves. An effort is, however, being made to obtain an independent license-conferring school.

Canada.—The early history of homœopathy can be traced back nearly to 1850 in the province of Quebec. In the Dominion of Canada the various provinces control the licensing of physicians, excepting in Quebec, which is the only province having a separate homœopathic board of examiners. This is under the control of the Montreal Homœopathic Association, and is known as the College of Homœopathic Physicians and Surgeons of Montreal. Three examiners are annually appointed by the association. Successful candidates receive the diploma of the college, and are entitled to add to their degree the letters M.C.H.P.S. A certificate of successful examination is forwarded to the lieutenant-governor at Quebec, who, "if satisfied of the loyalty, integrity, and good morals of the applicant, may grant him a license to practise surgery, physic, and midwifery, or either of them, in the province of Quebec." The word "loyalty" has been decided by the provincial secretary to mean a British subject. This is the only Government medical license now issued in the British empire, the others being by provincial boards or colleges of physicians and surgeons. In this province there are seventeen active practitioners of homœopathy. In 1894 there was no homœopathic institution in the province; at present the Montreal Homœopathic Hospital, valued at $20,000, and possessing already an endowment fund of $11,000, is in active operation. The hospital has forty beds, is well equipped for surgical and medical work, and has maternity and nurses' home annexes. The revenue is derived from the private rooms, which are extensively used by both schools for the treatment of patients. The facilities for surgical work in this hospital are superior to those of others in the city. The Phillips Training School of the hospital has about twenty graduates. New Brunswick, Nova Scotia, and Halifax have each two representatives of the system. In British Columbia there are four homœopathists, and in Manitoba four. Two homœopathic papers are published monthly — the *Homœopathic Record* in Montreal, and the *Homœopathic Messenger* in Toronto.

In 1870, in the province of Ontario, the three schools, allopathic, homœopathic, and eclectic, united for examining purposes into one board called the medical council, seventeen members representing the old school and five the two other systems. Besides these, the medical colleges sent eight representatives. Finally the eclectics were merged in the old school, the board appointing five of Hahnemann's followers for examining purposes; these designate two examiners in the branches of medicine bearing especially upon the homœopathic doctrine. There are eighty homœopathic physicians in the province, twenty of whom reside in Toronto. The homœopathic physicians are appointed on the staffs of the different allopathic hospitals and other public charities. There are homœopathic eye and ear specialists in London, Hamilton, and Toronto. Grace Hospital, with a capacity of 120 beds, is an imposing structure, and was begun as a dispensary in 1887. The hospital was incorporated in 1890, and in 1892 the present structure was erected.

Into Newfoundland, Prince Edward's Island, and the Labrador coast the system of Hahnemann has not penetrated.

Australia.—Homœopathy has been practised in Victoria since 1850 at least. It was introduced by a layman, who afterwards emigrated to India, there also to introduce the doctrine. The system is very popular in Adelaide, where there are at present eight homœopathic physicians. At Melbourne there are nine physicians of the new school, and a homœopathic hospital. In Sydney there are a dozen doctors practising the system, and ten chemists who dispense homœopathic medicines. Albury has one physician; Bendigo, one, and a chemist; Brisbane, one; Casino, one; Geelong, one, a dispensary, and a chemist; Maitland, one; and Freemantle, one. There are also homœopathic physicians in Christchurch and Dunedin in New Zealand. In the towns of Tasmania there are five.

United States.—Homœopathy was introduced into the United States by Dr Hans Birch Gram, who was born in Boston. His father being Danish, Gram in his eighteenth year went to Copenhagen, where he graduated in 1814. In 1823 he became acquainted with homœopathy, and brought a knowledge of it to America in 1825 when he settled in New York. The first homœopathic association was formed in 1833 in Philadelphia, the second in New York, 1834, and homœopathy became known in the different states somewhat in the following order:—New York, 1825; Pennsylvania, 1828; Louisiana, 1836; Connecticut, 1837; Massachusetts, 1837–38; Maryland, 1837; Delaware, 1837; Kentucky, 1837; Vermont, 1838; Rhode Island, 1839; Ohio, 1839; New Jersey, 1840; Maine, 1840; New Hampshire, 1840; Michigan, 1841; Georgia, 1842; Wisconsin, 1842; Alabama, 1843; Illinois, 1843; Tennessee, 1844; Missouri, 1844; Texas, 1848; Minnesota, 1852; Nebraska, 1862; Colorado, 1863; Iowa, 1871. After 1871 the spread of the system was rapid throughout every state in the Union. In the United States there are to-day 12,000 homœopathic physicians, of whom 1158 are women. Their numerical relation to all other sects is about 12·51 per cent. There are nine national societies, of which the American Institute of Homœopathy is the largest, having 1900 members. There are two sectional societies, composed of members from four to eight states, 33 state societies with an aggregate of 4000 members, 88 local organizations with 4500 members, 22 medical colleges with alumni numbering nearly 14,000 (six having connected with them alumni associations numbering 4711), 42 clubs with 659 members, 90 general hospitals, 50 general private hospitals, 45 special public hospitals, 36 special private, and 50 other eleemosynary institutions. Of the hospital capacity, 195 contain 16,037 beds, or 6735 more than was reported in 1895. There are 58 dispensaries, treating 287,507 persons with 740,319 prescriptions annually, being 61,782 patients and 245,521 prescriptions more than in 1895. It is safe to say that the patrons of the system amount to several millions. Besides these it may be noted that departments of homœopathy are connected with the universities of Boston, Michigan, Iowa, Minnesota, and Kansas City. There are 33 medical journals in active operation, and text-books and monographs for homœopathic students in all departments of medicine and surgery, written by members of the homœopathic school.

Germany.—In 1810 Hahnemann published his *Organon*, which was the starting-point of homœopathy in Germany. In 1811 an endeavour was made to found an institution in Leipzig in which practitioners might learn the new method of treatment theoretically and practically, but it was not a success, as the entire tide of professional opinion was against the system. In 1829, at the celebration of the fiftieth anniversary of Hahnemann's doctorate, the German Central Society was organized, holding its first meeting in 1830. In the university hospital of Munich some experiments were made to test the efficacy of homœopathic medicines, but these were not successful. In 1831 the Government prohibited homœopathists from dispensing their own medicines; this was a severe blow to the system. In 1834 there was a division among the homœopathists themselves, which much retarded the progress of the school. A homœopathic hospital was established about this time (January 1833) in Leipzig, but there was such constant wrangling among the physicians connected with it that its sphere of usefulness was curtailed, and it was finally converted into a dispensary. The Baden Homœopathic Society was established in 1834. The homœopathic hospital in Munich was established in 1836, but suffered a similar fate to that of Leipzig, and was converted into a dispensary. The rather equivocal success of these hospitals in Saxony and Bavaria was in direct contrast to the fate of two newly established hospitals in Austria, one in Vienna and the other in Linz, which were very successful, and aroused great interest both among physicians and laymen. During the political confusion of 1846 and 1849 there was complete stagnation of everything medical in Germany. But during all these years, though the public institutions were few, the literature on homœopathic subjects became very extensive, and exercised a significant influence upon the system in all parts of the world. Hahnemann died in 1843, and on the 10th of August 1851 a bronze monument to him was unveiled at Leipzig. The Leipzig dispensary lived thirty-three years. From 1842 to 1874 there were treated in this institution 65,106 patients. In 1901 there were about 250 homœopathic physicians in Germany; they appeared to be strongest at Berlin, in the province of Brandenburg, in Pomerania and Westphalia, Saxony, Hessen, and in Würtemberg. The homœopathic hospital at Leipzig, which was reorganized some years ago, is in successful operation; its patronage is large, its polyclinics are well attended, and its dispensaries good. At Berlin ground has been purchased upon which to erect a magnificent hospital. The polyclinic at Charlottenburg is well directed, and is under the patronage of distinguished personages. Homœopathic physicians give instruction in homœopathy to medical students during the various semesters, and have published a large volume on homœopathic materia medica. There is also issued at Berlin *Die Zeitschrift des Berliner Vereins homöopatischer Aerzte*, and at Leipzig *Die Allgemeine Homöopatische Zeitung*, besides several popular homœopathic newspapers for laymen. There is a homœopathic hospital in Munich, supported by the Homœopathic Hospital Society (comprising 86 members) and by small fees charged for treatment at the clinics. Neither the state of Bavaria nor the city contributes to the maintenance of this institution. There are eight homœopathic physicians in Munich, four in Augsburg, two in Nuremberg, and one

each in Regensburg, Landshut, Gassan, Rosenheim, Ulm, and Fürth, making a total of twenty. There is one homœopathic central pharmacy in Munich, two in Augsburg, one in Regensburg, and one in Metzingen, where there is also a homœopathic institution for poor patients. Homœopathy is patronized in most of the cities as well as in the country among the peasantry, especially in the Alpine regions. Since the death of the last holder, the professorship of homœopathy at Munich has been abolished.

Belgium.—In Antwerp there are three homœopathic physicians, and it is the only city in Belgium where there is an official homœopathic dispensary for the poor. This institution was founded by the municipality in 1891, and the physicians are paid from the public funds. In 1892 the annual prescriptions numbered 2922; in 1899 they had increased to 11,224. In Brussels there are fifteen homœopathic physicians. In 1897 a homœopathic polyclinic was founded, which in 1898 issued 7673 prescriptions, and in 1899 the number increased to 9128. In Ghent there are six homœopathic physicians and a private dispensary. In all the other cities of Belgium there are one or more physicians of the new school, their number being thirty-five. There are two homœopathic societies in Belgium, and an excellent medical journal.

Austria-Hungary.—Homœopathy was introduced into Austria about 1817, and in 1819 its practice was forbidden by law. Shortly afterwards the physician attending the Archduke John became a homœopath. In 1825 the doctrine was introduced into Vienna. To test the efficacy of the system Francis I. ordered that experiments be made with homœopathic medicines, and for this purpose a ward furnished with twelve beds was allotted. The results were satisfactory to the new system, and it made gigantic strides in Vienna. During the cholera epidemic of 1836 an increased impetus was given to the new school by the reported brilliant successes of the treatment. Societies were founded and journals published. In 1846 a second hospital was founded. In 1850 a third hospital was opened, and clinical lectures upon the system were delivered. In 1873 the Society of Homœopathic Physicians was formed. Between the years 1873 and 1893 homœopathy declined. In 1901, in thirty-seven cities and towns there were to be found about fifty physicians and two hospitals, and it was estimated that about seventy-five more were scattered in Moravia, Bohemia, Tirol, Salzburg, and the coast provinces. In Hungary the situation remains about the same as in former years. There is still a professorship of homœopathy at the University of Budapest, now held by Dr Bakody, and homœopathic clinics are held at the new Rochus Hospital in Ulloi Street, and also in the homœopathic department of the Hospital Bethesda of the Reformed Community. The Elizabeth Hospital, exclusively homœopathic, has existed for many years. There are societies of homœopathic physicians in successful operation, but on the whole the people appear to be much more indifferent to the system than in Germany, where a great number of societies and laymen interest themselves in homœopathy, and where homœopathic physicians deliver popular lectures upon their creed. The members of such societies in case of illness procure homœopathic remedies from the pharmacies of their respective organizations. There is a homœopathic hospital of some importance and also a children's hospital flourishing in Vienna. The physicians of the new school number less than a dozen.

Russia.—The homœopathic system of medicine was introduced into Russia in 1823. In 1825 great impetus was given to the new doctrine by the conversion of Dr Bigel, physician to the Grand Duke Constantine. In 1829 the grand duke ordered a series of experiments to be conducted to prove the truth or fallacy of homœopathy, and they demonstrated the success of the new school. In 1841 a hospital was established in Moscow, and in 1849 similar institutions were founded in Níjni-Novgorod. In St Petersburg from 1835 to 1845 there were sixteen homœopathic physicians. From 1845 to 1855 there was neither increase nor decrease in the number. From 1855 to 1865 the number had decreased to thirteen. In Moscow about the year 1875 there were thirty physicians practising homœopathy. In 1901 there were seventeen physicians in St Petersburg, three pharmacies, three dispensaries, and twelve hospitals. Homœopathy, it is said, continues to gain credit, penetrating to the remoter corners of the empire, while the number of its followers increases amongst all classes; but as will be seen by the foregoing figures, the number of homœopathic physicians rather decreases. There are at present 73 doctors who are practising the homœopathic method: In St Petersburg 17, Moscow 7, Odessa 7, Warsaw 6, Kiew 3, Riga 3, Charkow 2, Vilna 3, Tiflis 3, Dwinsk 2, Jitomir 2, and one each in Lodz, Lublin, Tilsit, Viatka, Yalta, Astrachan, Ekaterinoslaw, Gorodischtche, Gory, Gotopulow, Grodno, Insar, Kamenetz-Podolsk, Kanzeropol, Maikop, Pensa, Rostov, Saratow, Schidlovietz, Simferopol, Taganrog, Trostianetz. The number of medical men not being sufficient to satisfy the demand, in many places apothecaries and amateurs are acting as physicians; indeed, in many portions of Russia, especially in the villages, the followers of homœopathy are thrown upon their own resources. The number of homœopathic pharmacists has increased since 1896 from 17 to 26, *i.e.*, at St Petersburg 5, Moscow 2, Warsaw 2, Odessa 2, Charkow 2, Riga 2, Vilna 2, Rostow on Don 1, Novotcherkaosk 1, Taganrog 1, Kiew 1, Berditetew 1, Tiflis 1, Jitomir 1, Taratars 1, Viatka 1. Homœopathic societies are in more or less successful operation in the following cities: St Petersburg 3, Odessa 2, Charkow, Warsaw, Kiew, Moscow, Tiflis, Vilna, Stavropol, Jalta, Poltawa, and Thsernigow each 1. Two of the societies in St Petersburg, the "Hahnemann" in Odessa, and those in Warsaw and Charkow, possess pharmacies of their own, yielding fair profits and affording the possibility of increasing their means independently of private charity. There are two homœopathic journals, one of them published at St Petersburg and the other at Charkow. St Petersburg counts five dispensaries and one hospital. In 1881 the civil engineers proposed to commemorate the virtues of the Emperor Alexander II. by the erection of a hospital; a committee for collecting funds was created, and 58,064 roubles were handed to the Charity Society of the followers of homœopathy at St Petersburg for the erection and founding of a homœopathic hospital. The foundation stone of the edifice was laid on 19th June 1893, the Emperor Alexander III. giving 5000 roubles. The inauguration of a new dispensary and a pharmacy took place on the 19th of April 1898, and the hospital itself, intended originally for fifty beds, was opened on the 1st of November 1898. There are sixteen free beds, three of them being in the name of the Emperor Nicholas, the Empress Maria Feodorovna, and the Emperor Alexander III. On the 28th of January 1899 an imperial edict was issued granting the rights of public service to the doctors of the hospital and dispensaries of the Charity Society, thus placing them on an equality with the doctors of the prevailing medical school.

France.—Homœopathy was first introduced into France in 1830 by Count de Guidi, doctor of medicine, doctor of science, and inspector of the university, who practised in Lyons. About the same year Dr Antoine Petroz, widely known by his *Grand Dictionnaire des Sciences Médicales*, began practising homœopathy in Paris, and his establishment became the headquarters of the new system there. In 1835 Hahnemann himself came to the capital. In 1832 the homœopathic method of treating disease was introduced into the Hospice de Choisy, and in 1842 into the hospital of Carentan. Tessier practised the new doctrine in his wards in the Hospital St Marguérite, and in the Children's Hospital up to the year 1862, when he retired. The first homœopathic society was established in 1832 (the Société Gallicain), Hahnemann becoming president in 1835; in 1845 the Société de Médecine Homéopathique was organized; and in 1860 the two were united for the better interests of the school. This society is still in existence. The first public lecture in the new system was given in January 1835, the course being continued annually to 1869, when it was suspended. In 1901 there were at Paris three hospitals—the Hospital St Jacques with fifty-five beds, the Hahnemann Hospital with thirty-five beds, and the new Protestant Hospital for Children with twenty-five beds. The number of patients treated during the year 1900 at the three hospitals united averaged 630. At Lyons there is the Hospital St Luc, which is in a prosperous condition. The free consultations at the numerous dispensaries have remained stationary for the past few years. The medical journals published in French are *L'Art Médical*, *La Revue Homéopathique Belge*, *Journal Belge d'Homéopathie*, *La Thérapeutique Intégrale*, *La Revue Homéopathique Française*. Important scientific works have appeared on pathology and materia medica and tuberculosis. There are 56 physicians now practising homœopathy in Paris, and 151 in the provinces, making a total of 207. There are 22 dispensaries scattered through the republic. Pharmacies are numerous in all the larger cities and towns. In the year 1900 the medical officers of the republic having supervision over the medical department of the International Exhibition officially recognized the members of the homœopathic school, and arranged for the proper accommodation and reception of the International Congress of Homœopathic Physicians held in June. On the 30th of that month, with appropriate ceremonies, the remains of Hahnemann were removed from the cemetery of Montmartre and deposited in Père-la-Chaise, and a monument bearing a suitable inscription was erected to the memory of the founder of homœopathy.

Italy.—The Austrians when they entered Naples in 1821 brought homœopathy into Italy, the general in command of the army being a devoted friend of Hahnemann. In 1828 Dr Count Sebastian de Guidi came from Lyons and assisted in spreading the doctrine. During the period from 1830 to 1860 many physicians practised homœopathy, and the literature on the subject became extensive. A homœopathic clinic was established and a ward opened in Trinity Hospital at Naples, and a homœopathic physician was appointed to the Count of Syracuse. During the severe cholera epidemics of 1854, 1855, 1865 the success of homœopathic treatment of that disease was so marked under the care of Dr Rubini that the attention of the authorities was directed to the

system. In 1860 the homœopathic practice was introduced into the Spedale della Cesarea, and since that period homœopathy has been recognized with more or less favour in most of the cities. In the villages and smaller towns it is practically unknown, as indeed is all advanced medical therapeutics. At the present time the Italian Homœopathic Institute is recognized by royal warrant as an established institution, and its regulations are approved by the Government. It is composed of about fifty members, the greater part of whom are physicians and the remainder laymen, representing the majority of those following homœopathy in Italy. In Turin, the legal seat of the Homœopathic Institute, there is a hospital under the management of the State Association. A bequest of 150,000 francs has been made to the town of Verona for the establishment of ten charity beds in the general hospital for special homœopathic treatment, and Genoa also has obtained 20,000 francs as the nucleus of a fund for a similar purpose. Free dispensaries are now in operation in Rome, Florence, Naples, Milan, and Turin. The Academy of Medicine at Palermo provides a good dispensary for the care of the sick. The number of physicians who practise homœopathy has not increased for some years, but the former opposition and ridicule of the old-school physicians have entirely ceased. Apart from the allo-homœopathic pharmacies, which generally do not inspire great confidence, there are homœopathic pharmacies in Rome (1), Naples (4), Palermo (1), and Florence, Milan, and Turin (each 1). In Rome there are 5 practitioners; Naples, 12; Turin, 6; Milan, 3; Bologna, 1; Palermo, 3; Messina, 1; Florence, 1; Bavagua, 2; Casale, 1; Laloggia, Bellante, Noto, Melitello, Vittoria, Senorbi (Sardinia), each 1. The homœopathic medical press consists of the *Revista Omiopatica*, established in 1855, and *L' Omiopatico in Italia*, which is the organ of the Italian Homœopathic Institute, and first appeared in 1884. At Turin there is a small hospital with ten beds under the direction of homœopathic physicians.

Spain.—Homœopathy was introduced into Spain in 1829 by a physician to the Royal Commission sent by the king of Naples to attend the marriage of Maria Christina with Don Ferdinand VII. Shortly after this, a merchant of Cadiz visited Hahnemann in Coethen, and was cured of a serious disorder; he returned to Spain with a supply of homœopathic literature, and immediately sent a medical student to Leipzig to study the new system. In 1843 many cases of cholera were treated homœopathically in Madrid. The civil war, which did not terminate until 1840, arrested all medical investigation in Spain, but in 1843 there still existed in Madrid five pharmacies and a number of homœopathic physicians. About this time Dr Tosi Nuñez returned from an investigation of the new system with Hahnemann, and owing to his success in the treatment of disease was created one of the physicians of the bedchamber to the queen, who soon afterwards conferred upon him the title of marquis, with the grand crosses of the Charles III. and of the Civil Order of Beneficiencia. This recognition by high authority gave an impetus to homœopathy which has continued ever since. In Barcelona to-day there are no fewer than 44 homœopathic physicians and 3 pharmacies. The public institutions are the Academia Homœopatica, the Clinica Homœopatica, and the Dispensario Homœopatica, the last being under the supervision of the Academy. There are 3 veterinary surgeons in the city. In Madrid there are 10 physicians of the new school, 3 homœopathic chemists, and 2 homœopathic hospitals. In Valencia there are 7 physicians who practise the system. In Seville the Institut del Dessert is exclusively homœopathic, while there are between 60 and 70 physicians scattered throughout the provinces. In the Balearic Islands a journal devoted to the interests of the school was published, and in the Antilles the system is known and practised.

Denmark.—Homœopathy was unknown in Denmark until the year 1821, when Hans Christian Lund, a medical practitioner, adopted it. Hahnemann, however, had been both before and after that time consulted by Danes, and consequently homœopathic therapeutics was recognized in different parts of the country. Lund translated many of Hahnemann's works into Danish, as well as those of other eminent members of the new school. The spread of the system, however, has been very slow, and in many portions of the country it is unheard of. There are 8 homœopathic physicians in Denmark, 5 being in Copenhagen, 1 in Aarhus (in Jutland), 1 in Vester Broenderslev (Jutland), and 1 on the island of Bornholm. There is at present no hospital wherein homœopathy is practised, but £15,000 has already been subscribed for the purpose of erecting one, which will be built when the fund reaches £20,000 or £25,000. There is no special homœopathic pharmacy in Copenhagen, as all the chemists dispense homœopathic medicines. There are two homœopathic veterinary surgeons in Copenhagen.

Holland.—In Holland homœopathy makes but little progress, but there are now in every large town at least one homœopathic practitioner and several dispensaries. One homœopathic newspaper is published at Rotterdam. Amsterdam, Alfen, Apeldoorn, Haarlem, Nimeguen, Utrecht, Zaandam, and Zwolle have each a homœopathic physician. At The Hague there are two, and at Rotterdam two. At Utrecht the Society for the Propagation of Homœopathy in the Netherlands is in a flourishing condition.

Sweden and Norway.—In Sweden and Norway but little is known of the new system at present. It was introduced into Sweden in 1826. In 1855 an attempt was made to open a homœopathic polyclinic in Stockholm, which was unsuccessful. In 1865 an American physician settled in Norrköping and expounded Hahnemann's doctrine, and in 1868, after considerable opposition, a polyclinic was opened at Stockholm, but it was not of long continuance.

Switzerland can boast of but few physicians espousing the doctrine of Hahnemann. In the late 'fifties it excited some attention, and polemic articles were published in 1864 and 1865 to defend it from attacks by the professors of the university at Bern. A society was also established in the latter city, and a second in Aarau for the promulgation of homœopathy. A work on materia medica was issued in 1866, and in 1868 a journal devoted to the interests of the new system was issued. Since that period the system has seemed to stagnate. In Basel there is a small homœopathic hospital containing twelve beds. According to the latest information, the physicians of the new school are distributed as follows:—Aarau, 1; Basel, 4; Bonne, 4; Biel, 1; Geneva, 2; Grundelwald, 1; Mouthey, 1; Mithlenen (Bernese Oberland), 4; St Gallen, 1; Hun, 1; Zurich, 3.

South America.—In South America the system of Hahnemann is best known in Brazil, although there are homœopathic physicians scattered throughout the different states. It was introduced in 1818, and for a long time had a precarious existence. The Homœopathic Institute of Brazil was founded in 1842, with 56 members; and soon afterwards a special school for homœopathic instruction was opened, with a scheduled course of lectures. In 1847 dissension among the professors of homœopathy divided the old society, and a new organization was formed by the seceders, called the Academia Medico Homœopatha, but the record reads, "like nearly all the other institutions and societies in Brazil, it died of the chronic maladies of selfishness and envy." Bahia and Rio de Janeiro have witnessed many struggles in their efforts to place homœopathy on a sound footing in South America. Among the periodicals published representing the new school methods were the *Sciencia* and the *Hahnemannesta*, in 1846; the *Homœopatha*, in 1850; the *Medico Populao*, in 1851; and the *Athleta*, in 1852. In 1873 cholera raged in Rio, and the Government organized temporary infirmaries for the treatment of the disease. Some of these were placed under homœopathic supervision, and their work was fairly commendable. Of late years there has been little extension of the homœopathic principle in South America. There are at present homœopathic physicians in Amazonas, Pard-Belem, Maranhão, Pernambuco, Bahia, Rio de Janeiro (Campos), Maje, Marica, São Joao da Barra Nictheroy, Rio de Janeiro (capital), São Paulo, Campinas, São Paulo-Capital, Rio-Claro Tatuhij, Santos, Santa Catharina, São-Pedro, Pelotas, Porto Alegre, Rio Grande, and San Gabriel.

West Indies.—In Barbados there are five homœopathic physicians, an oculist, and an aurist.

Cuba.—Homœopathy was brought into Havana in 1842. In 1856 there was a weekly journal published in that city and also one in Santiago. In 1876 there were sixteen homœopathic physicians practising in Havana. There were also a Casa de Salud, or private hospital, where the system was practised, and one special homœopathic pharmacy. Homœopathy has declined in Cuba. In 1901 there were only four homœopathic physicians in Havana.

India.—Homœopathy is practised in Calcutta, and has a moderate clientèle. In that city alone are thirty homœopathic physicians and seven chemists. There are two journals published in the interests of the school, one the *Indian Review*, the other the *Calcutta Journal of Medicine*. A school of homœopathy and a hospital are in full operation. The Maitra Homœopathic Dispensary is doing serviceable work. Books have been published on the treatment of cholera, on the therapeutics of the plague, besides several homœopathic works in the Bengali language. There are homœopathic physicians in a few of the large towns, and a number of native-born Indians have at different times been sent to the homœopathic colleges in the United States to obtain medical degrees.

China.—There are two homœopathic physicians at Ningpo, where there is also a hospital and medical school, but it is impossible to obtain accurate information on the status of homœopathy in the various sections of the vast Chinese empire.

Cape Colony.—In Cape Town there are three physicians practising homœopathy, and in Kimberley one. (W. T. H.)

Honduras, a country of Central America, lying between 13° 10′ and 16° 2′ N., and 83° 20′ and 89° 30′ W. Here, as in other Central American states, there are but two seasons, the wet, from May to

November, and the dry, from November to May. On the moist lowlands of the Atlantic coast the heat is oppressive, but on the highlands of the interior the climate is delightful. At Tegucigalpa, on the uplands, a year's observations showed the maximum temperature to be 90° F. in May, and the minimum to be 50° F. in December, the range of variation during the whole year being within 40° F. The area is estimated at 46,250 square miles, and the population in 1900 was 587,500. The population of each of the fifteen departments was as follows in 1895: Tegucigalpa, 58,984; El Paraíso, 31,245; Choluteca, 33,665; Valle, 24,133; La Paz, 20,616; Comayagua, 21,713; Yoro, 16,424; Cortéz, 13,665; Santa Barbara, 26,008; Copán, 44,798; Gracias, 35,533; Intibucá, 18,957; Olancho, 35,737; Colón, 13,409; Bay Islands, 3990. The number of foreigners within the Republic was put at 6021. The European element in the population is small, the mass of the inhabitants being of Indian and mixed blood. The chief towns, with their populations in 1895, are: Tegucigalpa, the capital, 18,000; Juticalpa, 8000; Choluteca, Nacaome, and Santa Rosa, 7000 each; Gracias, 6000; Yoro, Yuscaran, and Comayagua, 5000 each; Truxillo, 3000.

The constitution, as amended in 1880, provides for a Legislative Chamber, consisting of deputies chosen for four years by direct popular vote. The number of deputies should be in the proportion of one for every 10,000 inhabitants, but, pending the formation of electoral districts, each department returns three, except the Islands, which return one. The President of the Republic is chosen for four years by direct popular vote, but failing an absolute majority, the Legislative Chamber chooses one of the three that received most votes. The President is eligible for a second, but not for a third consecutive term. The members of the cabinet are appointed by the President; they may take part in the discussions of the Chamber, but have no vote. The governors of the fifteen departments are appointed by the President.

Justice.—Justice is administered by a supreme court of five judges at Tegucigalpa, four appeal courts, courts in the departmental capitals, and subordinate local tribunals.

Religion and Instruction.—Though the prevailing faith is Roman Catholic, all forms of religion are free, and the state does not contribute to the support of any.

Primary instruction is obligatory, gratuitous, and secular. In 1898–99 there were within the Republic 627 primary schools, with 29,690 pupils. For secondary instruction there are 23 schools, with in all 718 pupils, and for manual and technical instruction there is a school directed by European masters at Tegucigalpa. In the capital there is also a central university, with faculties of law, medicine, science, and political science; at Comayagua there is a second faculty of law. In the year 1898–99 the sum of 110,060 pesos (£10,560) was devoted to instruction.

Defence.—Military service is obligatory from the twentieth to the thirtieth year of age in the active army; from the thirtieth to the fortieth in the reserve. The total force in 1898 amounted to 36,686 men. The Republic possesses two small steam revenue cutters.

Finance.—Of the revenue, 42 per cent. is derived from customs, and 34 per cent. from spirit and gunpowder monopolies, while war, finance, and public works demand the largest share of the expenditure. The revenue and expenditure for the years ending 30th June 1895, 1897, and 1899 were as follows (conversion being made at the rate of 23d. to the peso):—

	1895.	1897.	1899.
Revenue	£208,584	£229,296	£225,720
Expenditure	120,185	330,426	228,340

For the year 1900–01 (at the same conversion rate) the revenue was estimated at £232,610 and the expenditure at £232,015.

The existing external debt was contracted by a conversion loan in 1867, and three railway loans, 1867, 1869, and 1870, the total outstanding principal amounting in 1900 to £5,398,570. No interest has been paid since 1872, and the principal and arrears of interest together in 1900 amounted to £18,298,258. The official statement respecting the public debt on 31st July 1899 put its amount at 1,800,812 pesos, or £172,880, the entire external debt being simply ignored.

Production.—Bananas are the principal agricultural produce of Honduras. This fruit is easily, cheaply, and quickly grown, and its cultivation is steadily extending on the northern coast. Coffee is also grown, but as the bushes require some time to come to maturity, and the market prices of the product have for some years been low, coffee planting does not extend. The high prices obtained for rubber have aroused interest. Tobacco of fine quality is grown, but in such small quantities that there is none for export. Other products are cocoa-nuts, furniture wood, and sarsaparilla. The cattle industry is usually prosperous, large numbers of living animals and of hides being exported. Gold and silver mining are carried on successfully, but the annual output is not on the increase. Of local industries, the manufacture of straw hats is the most conspicuous.

Commerce.—The imports consist mostly of articles of common use or consumption—cotton goods, hardware, flour, provisions, with agricultural implements and mining machinery; while the exports consist of agricultural and mineral products. In 1898 the total imports amounted to the value of £273,080; in 1899, to £280,804. In 1898 the exports were valued at £257,572; in 1899, at £231,014. The exports in 1899 comprised bananas, £89,068; coffee, £10,644; cocoa-nuts, £13,181; cedar and mahogany, £8652; cattle, £26,136; mineral products, £67,696. The exports of gold in the year 1897–98 amounted to the value of £2780; in 1898–99, £2310; of bar silver in 1897–98, £92,860; in 1898–99, £55,466. The trade is mostly with the United States, which in 1899 sent 73 per cent. of the imports and took 83 per cent. of the exports. Germany sent 12 per cent. of the imports and Great Britain 8 per cent. In 1900 the British exports to Honduras amounted to £52,205, and the imports into the United Kingdom from Honduras to £2967.

Communications.—Means of communication are very defective. The only railway in the country is that from Puerto Cortez to La Pimienta, a distance of about 68 miles. This is a section of the proposed inter-oceanic railway for which the external debt of the Republic was incurred. For the completion of the line concessions, one after another, were granted, and expired or were revoked. The contract now in force (ratified 26th May 1900) grants a twenty-five years' lease of the already constructed line at an annual rent of 15,000 pesos gold (£3000) to an American syndicate, which undertook to complete the railway to the Pacific within seven years. Other railways, including one along the Atlantic coast, are projected. The capital is connected with other towns by fairly well made roads, which, however, are not kept in good repair. To Tegucigalpa from San Lorenzo the journey takes about three days, and from San Pedro Sula about seven days. Other roads have been contracted for, but at present in the country generally all travelling and transport are by mules and ox-carts over roads which defy description.

Honduras joined the Postal Union in 1879. In the year 1898 there were 241 post offices, and 1,106,034 pieces were handled. The telegraph lines, which are Government property, had in 1899 a length of 3186 miles, and were served by 155 telegraph offices, through which 538,941 messages passed in the course of the year.

Money and Credit.—There is at present only one bank, the Banco de Honduras at Tegucigalpa. It has the privilege of issuing bills, which are legal tender for all duties, taxes, and debts due to the Government; but there is no paper currency. The monetary unit is the silver peso, weighing 25 grammes, ·900 fine, and worth about 22d.

The metric system of weights and measures was introduced by law 1st April 1897, but the old Spanish system continues in general use.

(W. W. R.)

Honduras, British, a British colony in Central America, on the eastern side of the base of the peninsula of Yucatan, with an area, including outlying cays, of

7562 square miles, lying between 18° 29′ and 15° 54′ N., and 89° 10′ and 87° 50′ W. It consists of a low-lying coast-line, intersected by rivers and lagoons, and fringed by cays, rising to higher ground in the interior, the Cockscomb mountains reaching a height of 4000 feet. The characteristic soils of the colony are known as Cahoon ridge (the vegetable alluvium along the river valleys), the Pine ridge (sandy tracts covered with pines, scrub, and wire grass), and Broken ridge (intermediate between these two). Besides these, there are swamp, savannah, and mountain. The Pine and Cahoon ridges afford abundant pasturages for cattle. Of the land in the colony, 50,000 acres are returned as cultivated and 4,573,870 as uncultivated. About 3,102,843 acres of land are in private ownership, and 1,736,565 remain ungranted—the latter area including lagoons, &c. Population (1900), 36,998; death-rate per thousand, 24·055. The population consists of (1) native Indians, to be found chiefly in forest villages in the west and north of the colony away from the sea-coast; (2) descendants of the English buccaneers, mixed with Scottish and German traders; (3) the woodcutting class known as "Belize Creoles," of more or less pure descent from African negroes imported, as slaves or as labourers, from the West Indies; (4) the Caribs of the southern districts, descendants of the population deported in 1796 from St Vincent, who were of mixed African and Carib origin; (5) a mixed population in the south, of Spanish-Indian origin, from Guatemala and Honduras; and (6) in the north another Spanish-Indian group which came from Yucatan in 1848. The mean maximum summer temperature is 90°. The maximum in 1900 was 94·8 (in May) and the minimum 51·8 (in February). The rainiest months are generally those from June to November. The average annual rainfall at Belize is about 80 inches. The value of the imports in 1900 was £239,754, and of the exports £260,113. The following are the principal articles of export, and their values in that year: mahogany, £87,717; logwood, £86,507; bananas, £18,221; cocoa-nuts, £5209; cedar, £3943; plantains, £3599.

BELIZE, the capital, at the mouth of the river of the same name, with a good roadstead for ships, is situated in 17° 29′ N. and 88° 8′ W.

The colony has fine soil, adapted to many kinds of tropical products, but most of it is covered by primeval forest or bush. There are no good roads, but there is excellent river and sea-coast communication. No minerals exist in sufficient quantities to justify mining, and an attempt made to develop a sponge industry was abandoned. The chief industry (now 200 years old) is the cutting of mahogany and logwood; other woods are cedar, rosewood, bullet-tree, fustic, lignum vitæ, santa maria, ironwood, &c. After timber, the principal products are bananas (exported to the United States), sugar, and rum (for home consumption only), Indian corn, cocoa-nuts, plantains, and cacao. The revenue in 1900 was £57,945 (of which £34,050 came from customs), and the expenditure was £49,240. The public debt was £33,763. The standard of currency is the gold dollar of the United States, British gold being legal tender. Subsidiary silver and bronze currency is coined specially for the colony, and there is a Government note issue. The tonnage of vessels (nearly all British, American, or Norwegian) entered during 1900 was 170,917 (sailing 24,371, steam 146,546), and cleared 169,180 (sailing 22,919, steam 146,261). The churches represented are Roman Catholic, Anglican, Wesleyan, Baptist, and Presbyterian; but none of them receives assistance from public funds. The bishopric of British Honduras is part of the West Indian Province of the Church of England. School-fees are charged at and grants-in-aid are made to elementary schools, which since 1894 have been under the control of a board, on which the religious bodies managing the schools are represented. In 1900 there were 38 schools, with 3391 children on the books and 2383 in average daily attendance. There are two police forces, the British Honduras constabulary consisting of 50 officers and men (of whom 18 are mounted), all stationed in the northern district; and the British Honduras police (an unmounted force) distributed in the other districts, consisting of 75 officers and men. There is a volunteer force (the Belize Light Infantry Corps) of 177 officers and men, and a volunteer fire brigade of 335 officers and men. There are no railways or telegraphs; in 1900 the revenue from the post office was £2211, and the number of mail pieces 254,451; the money order system is in force. In 1884 letters patent were proclaimed constituting the office of governor and commander-in-chief of British Honduras, which rendered the colony independent of Jamaica, to which it had been attached since its development from a settlement into a colony in 1862. The Legislative Council consists of the governor, with three official and five unofficial members nominated by the Crown. The Executive Council consists of the governor and five members (three *ex officio* and two nominated). The English common law extends to the colony, subject to modification by local ordinances. (F. CU.)

Honfleur, French town, in the arrondissement of Pont l'Évêque, department of Calvados, north-east of Caen, with terminal station on railway 124 miles from Paris. The port comprises the tidal harbour, floating basin of the west, basin of the centre, basin of the east, and fourth basin. The depth of water, ordinary spring tide, on the bar of the tidal harbour is 21 feet, and on the sill of the three first-named basins, respectively, 16·7, 20, and 22 feet. The total length of quayage is 10,915 feet. There entered in 1899 348 vessels of 146,646 tons (from England 260, of 76,097 tons), and cleared 352, of 150,993 tons; besides which there entered, in connexion with the coasting trade, 357 vessels of 16,724 tons, and cleared 354, of 16,730 tons. Population (1881), 9012; (1901), 9610.

Hong Kong, an important trading centre and military and naval position, belonging to Great Britain, situated on the south side of the Chinese province of Kwang-Tung. It is separated from the mainland by a narrow pass of about a quarter of a mile. A good military road, about 22 miles long, encircles the island. Hong Kong or Victoria harbour constantly presents an animated appearance, as many as 240 guns having been fired as salutes in a single day. Its approaches are strongly fortified. The steaming distance from Singapore is 1520 miles. Victoria, the capital, often spoken of as Hong Kong (population over 166,000, of whom about 6000 are European or American), stretches for about 4 miles along the north coast. Its breadth varies from half a mile in the central portions to 200 or 300 yards in the eastern and western portions. The town is built in three layers. The "Praya" or esplanade, 50 feet wide, is given up to shipping. Under the Praya reclamation scheme the land frontage will be extended by 250 feet and a depth of 20 feet secured at all states of the tide. A further extension of the naval dockyard was begun in 1902, and a new commercial pier was opened in 1900. The main commercial street runs inland parallel with the Praya. Beyond the commercial portion, on each side, lie the Chinese quarters, wherein there is a closely packed population. In 1888, 1600 people were living in the space of a single acre, and over 100,000 were believed to be living within an area not exceeding half a mile; and the overcrowding does not tend to diminish, for in one district, in 1900, it was estimated that there were at the rate of 640,000 persons on the square mile. The average, however, for the whole of the city is 126 per acre, or 80,640 per square mile. The second stratum of the town lies ten minutes' climb up the side of the island. Government House and other public buildings are in this quarter. There abound "beautifully laid out gardens, public and private, and solidly constructed roads, some of them bordered with bamboos and other delicately-fronded trees, and fringed with the luxuriant growth of semi-tropical vegetation." Finally, the third layer, known as "the Peak," and reached by a cable tramway, is dotted over with private houses and bungalows, the summer health resort of those who can afford them; here a new residence for the governor was begun in 1900. Excellent water is supplied to the town from the Pokfolun and Tytam

reservoirs, the former containing 68 million gallons, the latter 390 millions.

Climate.—The temperature has a yearly range of from 45° to 99°, but it occasionally falls below 40°, and ice occurs on the Peak. In January 1893 ice was found at sea-level. The wet season begins in May, after showers in March and April, and continues until the beginning of August. During this period rain falls almost without intermission. The rainfall varies greatly, but the mean is about 90 inches. In 1898 only 57·025 inches fell, while in 1897 there were 100·03 inches; in 1899, 72·7 inches, and in 1900, 73·7 inches. The damp is extremely penetrating. During the dry season the climate is healthy, but dysentery and intermittent fever are not uncommon. Bilious remittent fever occurs in the summer months, and smallpox prevails from November to March. The death-rate for 1899 was 23·8 per thousand, but the average was raised by an outbreak of plague, which caused 1428 deaths, and in 1900 it was 23·9; the birth-rate in the same years being 4·3 and 3·3 per thousand respectively.

Population, &c.—The following table shows the increase of population:—

Year.	Eur. and Amer. Civil.	Chinese Civil.	Total (inc. Mil and Naval Establishments and Indians, &c).
1881	3040	148,850	160,402
1891	4195	208,383	221,441
1897	5532	233,280	246,880

The floating population was in 1897 given as 31,752, a slight reduction since 1891. In 1901 the population, including 13,237 on the military and naval establishment, amounted to 297,212. This is exclusive of 100,000, all Chinese, in the new territory.

There were, in 1900, 104 schools open (13 Government and 91 grant-in-aid), with an average attendance of about 6000 scholars The Queen's College provides secondary education for about 135 boys. There are several hospitals, one of which is a Government institution. There were in 1899 over 3000 accounts in the Hong Kong Savings Bank, with deposits amounting to about $1,100,000. The total strength of the police force in 1899 was 827 (114 European, 350 Indian Sikhs, and 221 Chinese). In 1899 the strength of the military garrison was 3226.

Industries.—Beyond the cultivation of vegetable gardens there is practically no agricultural industry in the colony. But although only 400 acres are cultivated on Hong Kong island, and the same number of acres in Kowloon, there are 90,000 acres under cultivation in the new territory, of which over 7000 acres were in 1900 planted with sugar-cane. Granite quarries are worked. The chief industries are sugar-refining, the manufacture of cement, paper, bamboo and rattan ware, carving in wood and ivory, working in copper and iron, gold-beating and the production of gold, silver, and sandal-wood ware, furniture-making, umbrella- and jinricksha-making, and industries connected with kerosene oil and matches. The manufacture of cotton has been introduced, and 12,000 spindles are already at work. Ship- and boat-building, together with subsidiary industries, such as rope- and sail-making, appear less subject to periods of depression than other industries.

Trade.—Hong Kong being a free port, there are no official figures as to the amount of trade; but the value of the exports and imports is estimated as about £50,000,000 in the year. Among the principal goods dealt with are tea, silk, opium, sugar, flax, salt, earthenware, oil, amber, cotton and cotton goods, sandal-wood, ivory, betel, vegetables, live stock, and granite. The following are the figures of ships cleared and entered:—

Year.	Tonnage.	British.
1880	8,359,994	3,758,160
1890	13,676,293	6,994,919
1898	17,265,780	8,705,648
1899	18,101,309	8,665,828
1900	18,445,133	9,155,198

The Chinese junks rank next to British ships in the amount of trade. In 1899, 77,722 of these represented a tonnage of 4,664,162, and in 1900 their tonnage was 3,500,128. German and Japanese ships followed next, the former with 1,917,744 tons in 1900.

Finance.—The revenue and expenditure are given below:—

Year.	Revenue.	Expenditure.
1880	$1,069,948	$948,014
1890	1,995,220	1,915,350
1898	2,918,159	2,841,805
1899	3,610,143	3,162,792
1900	4,202,587	3,628,447

The main sources of revenue are licences, rent of government property, the post-office, and land sales. The light dues were reduced in 1898 from 2½ cents to 1 cent per ton. There is a public debt of about £340,000, borrowed for public works, which is being paid off by a sinking fund. The only legal tender is the Mexican dollar, and the British and Hong Kong dollar, or other silver dollars of equivalent value duly authorized by the governor. There are small silver and copper coins, which are legal tenders for amounts not exceeding two dollars and one dollar respectively. There is also a large paper currency in the form of notes issued by the Chartered Bank of India, Australia, and China, the Hong Kong and Shanghai Banking Corporation, and the National Bank of China, Limited. The foundation of new law courts was laid in 1900.

Administration.—Hong Kong is a Crown colony, administered by a governor, executive council, and legislative council. The executive council consists of the holders of certain offices and of such other members as the Crown may nominate. In 1890 there were nine members. The legislative council consists of the same officials and of six unofficial members. Of these three are appointed by the governor (of whom one must be, and two at present are, members of the Chinese community); one is elected from the chamber of commerce, and one from the justices of the peace. Under the Peking Treaty of 1860 the peninsula of Kowloon (about 5 miles in area) was added to Hong Kong. The population is about 27,000. There are several docks and warehouses, and manufactures are being developed. Granite is quarried in the peninsula.

New Territory.—An agreement was entered into in 1898 whereby China leased to Great Britain for ninety-nine years the territory behind Kowloon peninsula up to a line drawn from Mirs Bay to Deep Bay, and the adjoining islands, including Lantao. The new district, which extends to 376 square miles in area, is mountainous, with extensive cultivated valleys of great fertility, and the coast-line is deeply indented by bays. The alluvial soil of the valleys yields two crops of rice in the year. Sugar-cane, indigo, hemp, peanuts, potatoes of different varieties, yam, taro, beans, sesamum, pumpkins, and vegetables of all kinds are also grown. The mineral resources are as yet unknown. The population was estimated at about 100,000 in 1899. It consists of Puntis (or Cantonese), Hakkas ("strangers"), and Tankas. The Puntis are agricultural and inhabit the valleys, but they make excellent traders. The Hakkas are a hardy and frugal race, belonging mainly to the hill districts. The Tankas are the boat people or floating population. In the government of the new territory the existing organization is being as far as possible utilized.

Honiton, a municipal borough, market town, and railway station, in the Honiton parliamentary division of Devonshire, England, 16 miles east-north-east of Exeter. The old church has been restored. An attempt has been made to revive the lace industry, in which only about 250 women and children are now engaged, as compared with some 2000 employed in 1880. There is an important trade in butter. Area, 3134 acres. Population (1881), 3358; (1901), 3271.

Honolulu, the capital of the Hawaiian Islands, situated on the south-eastern coast of Oahu, at the mouth of the valley of Nuuanu, which runs back 6 miles to the famous pass in the Koolau range of mountains known as the "Pali." It has a small but safe harbour, and its central position at the "Cross-roads of the Pacific" makes it an important port of call. It is connected by lines of steamers with San Francisco, Vancouver, Japan, Manila, and the Australian states, and by lines

of sailing vessels with Hamburg, Bremen, and Liverpool, as well as with Boston, New York, and other American ports. In the year 1899 its exports were valued at $15,369,664, and its imports at $16,709,534, so that the total foreign commerce of this port amounted to $32,079,198. In 1900 the population was 39,306, including some 10,000 Hawaiians, upwards of 15,000 Asiatics, nearly or quite 5000 Portuguese, and 8000 other whites. The taxable property of the city is assessed at twenty-four million dollars, but its actual value is probably 50 per cent. greater than this. There are five banks, several hotels, two theatres, and many substantial buildings of brick and stone in the business quarter. The public buildings would do credit to any civilized country. It possesses a well-equipped paid fire department, public water-works, and both public and private electric light works. There are also a telephone system with 1200 subscribers, and a system of street tramcars. The city contains fifteen churches, the services in which are conducted in five different languages. It also maintains several hospitals, a maternity home, the Lunalilo Home for aged Hawaiians, and an asylum for the insane. It is the chief educational centre of the islands, having more than sixty schools, public and private, attended by 6000 pupils of all nationalities. The admirable Bishop Museum of Polynesian ethnology and the Honolulu Public Library of 14,000 volumes deserve special mention. The city also boasts a flourishing Art League, which exhibits twice a year, and a long list of benevolent, literary, social, and political societies. Numerous publications are issued daily, weekly, and monthly in five different languages. Honolulu combines the conveniences of a progressive American city with the charms of a mild and equable climate and a tropical flora. (W. D. A.)

Hood of Avalon, Arthur William Acland Hood, Baron (1824–1901), English admiral, born on 14th July 1824, was the younger son of Sir Alexander Hood of St Andries, Somerset, 2nd baronet, and grandson of Captain Alexander Hood, R.N., who, when in command of the *Mars*, fell in action with the French 74-gun ship *Hercule*, 21st April 1798. At the age of twelve Hood entered the navy, and whilst still a boy saw active service on the north coast of Spain, and afterwards on the coast of Syria. After passing through the established course of gunnery on board the *Excellent* in 1844–45, he went out to the Cape of Good Hope as gunnery mate of the *President*, the flagship of Rear-Admiral Dacres, by whom, on 9th January 1846, he was promoted to be lieutenant. As gunnery lieutenant he continued in the *President* till 1849; and in the following year he was appointed to the *Arethusa* frigate, then commissioned for the Mediterranean by Captain Symonds, afterwards the well-known admiral of the fleet. The outbreak of the Russian war made the commission a very long one; and on 27th November 1854 Hood was promoted to be commander in recognition of his service with the naval brigade before Sebastopol. In 1855 he married Fanny Henrietta, daughter of Sir C. F. Maclean. In 1856 he commissioned the *Acorn* brig for the China station, and arrived in time to take part in the destruction of the junks in Fatshan creek on 1st June 1857, and in the capture of Canton in the following December, for which, in February 1858, he received a post-captain's commission. From 1862 to 1866 he commanded the *Pylades* on the North American station, and was then appointed to the command of the *Excellent* and the government of the Royal Naval College at Portsmouth. This was essentially a gunnery appointment, and on the expiration of three years Hood was made Director of Naval Ordnance. He was thoroughly acquainted with the routine work of the office and the established armament of the navy, but he had not the power of adapting himself to the changes which were being called for, and still less of initiating them; so that during his period of office the armament of the ships remained sadly behind the general advance. In June 1874 he was appointed to the command of the *Monarch* in the Channel Fleet, from which he was relieved in March 1876 by his promotion to flag rank. From 1877 to 1879 he was a junior lord of the Admiralty, and from 1880 to 1882 he commanded the Channel Fleet, becoming vice-admiral on 23rd July 1880. In June 1885 he was appointed first sea lord of the Admiralty. The intense conservatism of his character, however, and his antagonistic attitude towards every change, regardless of whether it was necessary or not, had much to do with the alarming state of the navy towards 1889. In that year, on attaining the age of sixty-five, he was placed on the retired list and resigned his post at the Admiralty. After two years of continued ill-health, he died on 15th November 1901, and was buried at Butleigh on the 23rd. He had been promoted to the rank of admiral on 18th January 1886; was made K.C.B. in December 1885; G.C.B. in September 1889; and in February 1892 was raised to the peerage as Lord Hood of Avalon, but on his death the title became extinct. (J. K. L.)

Hood, John Bell (1831–1879), American soldier, was born in Owingsville, Bath county, Kentucky, on 1st June 1831, and graduated at the U.S. Military Academy in 1853. Transferred to the cavalry service in 1855, he fought the Indians, and while first lieutenant was (1859–60) cavalry instructor at West Point. In 1861 he resigned to enter the Confederate service, and was rapidly promoted from colonel to lieutenant-general, serving throughout the Virginia campaigns of 1862 and 1863. He was severely wounded at Gaines's Mills and Gettysburg. With a great reputation for fighting, he was next sent to Tennessee to reinforce General Braxton Bragg, and at the battle of Chickamauga, September 1863, he lost a leg. Six months later he returned to duty undaunted, and in the spring of 1864 led a corps under General Joseph E. Johnston, whom he was selected to succeed when that prudent officer was relieved by President Jefferson Davis. General Sherman compelled his retreat from Atlanta, after several days of stubborn fighting; and when Sherman's march to the sea followed, Hood undertook a counter-movement into Tennessee. On the 30th of November Hood was repulsed with heavy loss at Franklin, but still pushing on, he was disastrously defeated by General George H. Thomas at Nashville on 16th December, and relieved of command. Hood was a bold and valiant officer, but too rash and wasteful of strength to command discreetly at this declining stage of the Confederacy. After the war he engaged in business in New Orleans, where he died of yellow fever on 30th August 1879.

Hoogeveen (*i.e.*, high fen or moor), a village and commune in the Dutch province of Drenthe, 12 miles north-east of Meppel. Among numerous other colonies for the culture of the moorlands of Holland, one was established here in 1772. The industries include factories for the cutting of peat by machinery. The supply of peat is, however, becoming exhausted, and the population (11,924) is beginning to decline.

Hooghly, or Hugli, a town and district of British India, in the Burdwan division of Bengal, taking their name from the river. The town, situated on the right bank of the Hooghly, 24 miles above Calcutta by rail, forms one municipality with Chinsura, the old Dutch settlement, lower down the river. Population

"Luff, Boy!" By J. C. Hook.

(By permission of B. Brooks and Sons.)

(1881), 31,177; (1891), 33,060. It contains a Government college with 181 students in 1896–97, two high schools with 575 pupils, a Mahommedan college with 66 pupils, a hospital with a Lady Dufferin branch for female patients, and twelve printing-presses, issuing one English and two vernacular periodicals. The DISTRICT comprises an area of 1223 square miles, with a population in 1881 of 1,015,005, and in 1891 of 1,076,710, giving an average density of 880 per square mile. Classified according to religion, Hindus numbered 842,077; Mahommedans, 189,469; Christians, 633, of whom 162 were Europeans; "others," 2117. In 1901 the population was 1,050,365. Land revenue and rates (including Howrah) were Rs.15,39,805; the number of police was 837; the number of boys at school in 1896–97 was 43,754, being 57·2 per cent. of the male population of school-going age; the registered death-rate in 1897 was 32·87 per thousand. The district is traversed for 40 miles by the main line of the East Indian Railway, with a branch of 22 miles to the pilgrim resort of Tarakeswar, whence a steam tramway has been constructed for a farther distance of 31 miles. The Eden canal irrigates about 6000 acres, and there are several embankments and drainage works. Silk and indigo are both decaying industries, but the manufacture of brass and bell-metal ware is actively carried on at several places, to the estimated value of Rs.2,56,000 a year. There are several jute mills, a large flour mill, two bone-crushing mills, and a brick and tile works, with an annual out-turn valued at Rs.1,78,000.

Hook, James Clarke (1819-——), English painter, was born in London, 21st November 1819. His father, James Hook, a Northumbrian by descent, Judge Arbitrator of Sierra Leone, married the second daughter of Dr Adam Clarke, the renowned commentator on the Bible, who gave to the painter his second name. Young Hook's first taste of the sea was on board the Berwick smacks which took him on his way to Wooler. He drew with rare facility, and determined to become an artist; and accordingly, without any supervision, he set to work for more than a year in the sculpture galleries of the British Museum. In 1836 he was admitted a student of the Royal Academy, where he worked for three years, and elsewhere learned a good deal of the scientific technique of painting from a nephew of Opie. His first picture, called "The Hard Task," was exhibited in 1837, and represented a girl helping her sister with a lesson. Unusual facility in portraiture and a desire to earn his own living took the student into Ireland to paint likenesses of the Waterford family and others: here he produced landscapes of the Vale of Avoca, and much developed his taste for pastoral art; later, he was similarly engaged in Kent and Somersetshire. In 1842 his second exhibited work was a portrait of "Master J. Finch Smith": in this year he gained silver medals at the Royal Academy, and in 1843 he was one of the competitors in the exhibition of cartoons in Westminster Hall, with a 10 by 7 feet design of "Satan in Paradise." In 1844 the Academy contained a picture of a kind with which his name was long associated, an illustration of the *Decameron*, called "Pamphilius relating his Story," a meadow scene in bright light, with sumptuous ladies, richly clad, reclining on the grass. The British Institution, 1844 and 1845, set forth two of Hook's idylls, subjects taken from Shakespeare and Burns, which, with the above, showed him to be cultivating those veins of romantic sentiment and the picturesque which were then in vogue, but in a characteristically fresh and vigorous manner. "The Song of Olden Time" (Royal Academy, 1845) marked the artist's future path distinctly in most technical respects. It was in this year Hook won the Academy gold medal for an oil picture of "The Finding the Body of Harold." The travelling studentship in painting was awarded to him for "Rizpah watching the Dead Sons of Saul," in 1846; and he went for three years to Italy, having married Miss Rosalie Burton before he left England. Hook passed through Paris, worked diligently for some time in the Louvre, traversed Switzerland, and, though he stayed only part of three years in Italy, gained much from studies of Titian, Tintoret, Carpaccio, Mansueti, and other Venetians. Their influence thenceforth dominated the coloration of his pictures, and enabled him to apply the principles to which they had attained to the representation (as Bonington before him had done) of romantic subjects and to those English themes of the land and sea with which the name of the artist is inseparably associated. "A Dream of Ancient Venice" (R.A., 1848)—the first fruit of these Italian studies—"Bayard of Brescia" (R.A., 1849), "Venice" (B.I., 1849), and other works assured for Hook the Associateship of the Royal Academy in 1851. Soon afterwards an incomparable series of English subjects was begun, in many pastorals and fine and brilliant idylls of the sea and rocks. "A Rest by the Wayside" and "A Few Minutes to Wait before Twelve o'clock" proved his title to appear, in 1854, as a new and original painter. After these came "A Signal on the Horizon," 1857; "A Widow's Son going to Sea," "The Ship-Boy's Letter," "Children's Children are the Crown of Old Men," "A Coast-Boy gathering Eggs," a scene at Lundy; the perfect "Luff, Boy!" (1859), about which Ruskin broke into a dithyrambic chant; "The Brook," "Stand Clear!" "O Well for the Fisherman's Boy!" (1860), "Leaving Cornwall for the Whitby Fishing," "Sea Urchins," and a score more as fine as these. The artist was elected a full Academician on the 6th March 1860, in the place of James Ward.

Hooker, Sir Joseph Dalton (1817-——), English botanist and traveller, son of the famous botanist Sir W. J. Hooker, was born on 30th June 1817, at Halesworth, Suffolk. He was educated at Glasgow University, and almost immediately after taking his M.D. degree there in 1839 joined Sir James Ross's Antarctic expedition, receiving a commission as assistant-surgeon on the *Erebus*. The botanical fruits of the three years he thus spent in the Southern Seas were the *Flora Antarctica*, *Flora Novæ Zelandiæ*, and *Flora Tasmanica*, which he published on his return. His next expedition was to the northern frontiers of India, and the expenses in this case also were partially defrayed by the Government. The party had its full share of adventure. Hooker and his friend Dr Campbell were detained in prison for some time by the raja of Sikkim, but nevertheless they were able to bring back important results, both geographical and botanical. Their survey of hitherto unexplored regions was published by the Calcutta Trigonometrical Survey Office, and their botanical observations formed the basis of elaborate works on the rhododendrons of the Sikkim Himalaya and on the flora of India. Among other journeys undertaken by Hooker may be mentioned those to Palestine (1860), Morocco (1871), and the United States (1877), all yielding valuable scientific information. In the midst of all this travelling in foreign countries he quickly built up for himself a high scientific reputation at home. In 1855 he was appointed assistant-director of Kew Gardens, and in 1865 he succeeded his father as full director, holding the post for twenty years. At the early age of thirty he was elected

a fellow of the Royal Society, and in 1873 he was chosen its president; he received three of its medals—a Royal in 1854, the Copley in 1887, and the Darwin in 1892. He acted as president of the British Association at its Norwich meeting of 1868, when his address was remarkable for its championship of Darwinian theories. Of Darwin, indeed, he was an early friend and supporter: it was he who, with Lyell, first induced Darwin to make his views public, and the author of *The Origin of Species* has recorded his indebtedness to Hooker's wide knowledge and balanced judgment. Sir Joseph Hooker is the author of numerous scientific papers and monographs, and his larger books include, in addition to those already mentioned, a standard *Student's Flora of the British Isles* and a monumental work, the *Genera Plantarum*, based on the collections at Kew, in which he had the assistance of Bentham. On the publication of the last part of his *Flora of British India* in 1897 he was created G.C.S.I., having been created a knight commander of that order twenty years before.

Hoorn, a town in the Dutch province of North Holland, on the Hoornsch Hop, an inlet of the Zuyder Zee, 27 miles by rail north-north-east of Amsterdam. Though in a decadent state, the town has erected a museum and (1893) a statue of Jan Pietersz Koen, the founder of Batavia, and has tramways to Alkmaar and Medemblik. The port owns seventy-nine vessels engaged in the fisheries of the Zuyder Zee. Population (1900), 10,714.

Hoosick Falls, a village of Rensselaer county, New York, U.S.A., on the river Hoosick and the Fitchburg Railway, at an altitude of 425 feet. It has a hilly site, and its plan is irregular. Its chief industry is the manufacture of agricultural implements. Population (1880), 4530; (1890), 7014; (1900), 5671, of whom 1092 were foreign-born.

Hopkins, Mark (1802–1887), American educationalist and writer on Christian ethics and evidences, was born in Stockbridge, Massachusetts, 4th February 1802. He graduated at Williams College, 1824, where, six years later, he became Professor of Moral Philosophy and Rhetoric. In 1832 he was licensed to preach in Congregational churches, and was President of Williams College from 1836 until 1872, when he resigned, but continued to teach moral philosophy in the college. As a teacher and writer he was fresh, clear, and stimulating, and his volume of lectures on *The Evidences of Christianity* (1846) was long a favourite text-book in American colleges. Of his other writings, the chief were *Lectures on Moral Science* (1862), and *The Law of Love and Love as a Law* (1869), a pleasant and suggestive compendium of Christian ethics. His general tone of thought and line of argument are at once optimistic and transcendental. Dr Hopkins took a lifelong interest in Christian missions, and was for many years President of the American Board of Commissioners for Foreign Missions (the American Congregational Mission Board). He died at Williamstown, 17th June 1887.

Hopkinson, John (1849–1898), English engineer and physicist, was born in Manchester on 27th July 1849. Before he was sixteen he attended lectures at Owens College, and at eighteen he gained a mathematical scholarship at Trinity College, Cambridge, where he graduated in 1871 as senior wrangler and first Smith's prizeman, having previously taken the degree of D.Sc. at London University and won a Whitworth Scholarship. Although elected a fellow and tutor of his college, he stayed up at Cambridge only for a very short time, preferring to learn practical engineering as a pupil in the works in which his father was a partner. But there his stay was equally short, for in 1872 he undertook the duties of engineering manager in the glass manufactories of Messrs Chance Brothers and Company at Birmingham. Six years later he removed to London, and while continuing to act as scientific adviser to Messrs Chance, established a most successful practice as a consulting engineer. His work was mainly, though not exclusively, electrical, and his services were in great demand as an expert witness in patent cases. In 1890 he was appointed director of the Siemens laboratory at King's College, London, with the title of professor of electrical engineering. His death occurred prematurely on 27th August 1898, when he was killed, together with one son and two daughters, by an accident the nature of which was never precisely ascertained, while climbing the Petite Dent de Veisivi, above Evolena. Dr Hopkinson presented a rare combination of practical with theoretical ability, and his achievements in pure scientific research are not less intrinsically notable than the skill with which he applied their results to the solution of concrete engineering problems. His original work is contained in more than sixty papers, all written with a complete mastery both of style and of subject-matter. His name is best known in connexion with electricity and magnetism. On the one hand he worked out the general theory of the magnetic circuit in the dynamo (in conjunction with his brother Edward), and the theory of alternating currents, and conducted a long series of observations on the phenomena attending magnetization in iron, nickel, and the curious alloys of the two which can exist both in a magnetic and non-magnetic state at the same temperature. On the other hand, by the application of the principles he thus elucidated he furthered to an immense extent the employment of electricity for the purposes of daily life. As regards the generation of electric energy, by pointing out defects of design in the dynamo as it existed about 1878, and showing how important improvements were to be effected in its construction, he was largely instrumental in converting it from a clumsy and wasteful appliance into one of the most efficient known to the engineer. Again, as regards the distribution of the current, he took a leading part in the development of the three-wire system and the closed-circuit transformer, while electric traction had to thank him for the series-parallel method of working motors. During his residence in Birmingham, Messrs Chance being makers of glass for use in lighthouse lamps, his attention was naturally turned to problems of lighthouse illumination, and he was able to devise improvements in both the catoptric and dioptric methods for concentrating and directing the beam. He was a strong advocate of the group-flashing system as a means of differentiating lights, and invented an arrangement for carrying it into effect optically, his plan being first adopted for the catoptric light of the *Royal Sovereign* lightship, in the English Channel off Beachy Head. Moreover, his association with glass manufacture led him to study the refractive indices of different kinds of glass; he further undertook abstruse researches on electrostatic capacity, the phenomena of the residual charge, and other problems arising out of Clerk Maxwell's electro-magnetic theory. His original papers were collected and published, with a memoir by his son, in 1901.

Hopkinsville, capital of Christian county, Kentucky, U.S.A., on the Louisville and Nashville and the Illinois Central Railways. It contains a state hospital for the insane, and South Kentucky College, a Christian institution. Population (1890), 5833; (1900), 7280, of whom 103 were foreign-born and 3243 were negroes.

HOPS AND HOP-GROWING.

Acreage, Production, and Consumption.

THE cultivation of hops in the British Isles is restricted to England, where it is practically confined to half-a-dozen counties—four in the south-eastern and two in the west-midland districts. In 1901 the English crop was reported by the Board of Agriculture to occupy 51,127 acres. The official returns as to acreage do not extend back beyond 1868, in which year the total area was reported to be 64,488 acres. The largest area recorded since then was 71,789 acres in 1878; the smallest was 49,735 acres in 1898. The difference is 22,054 acres, which represents the considerable proportion of nearly one-third of the maximum acreage. The extent to which the areas of hops in the several hop-growing counties vary from year to year is sufficiently indicated in Table I., which shows the

TABLE I.—*Hop Areas of England, 1895 to 1901—Acres.*

County.	1895.	1896.	1897.	1898.	1899.	1900.	1901.
Kent . . .	35,018	33,300	31,661	30,941	31,988	31,514	31,242
Hereford . . .	7,553	6,895	6,542	6,651	7,227	7,287	7,497
Sussex . . .	7,489	5,908	5,174	4,829	4,949	4.823	4,800
Worcester . .	4,024	3,800	3,591	3,567	3,788	3,964	4,029
Hants . . .	2,875	2,494	2,306	2,263	2,319	2,231	2,133
Surrey . . .	1,783	1,623	1,416	1,313	1,388	1,300	1,232

Total area . .	58,940	54,217	50,863	49,735	51,843	51,308	51,127

annual acreages over a period of seven years, 1895 to 1901. The proportions in which the acres of hops are distributed amongst the counties concerned vary but little year by year, and as a rule over 60 per cent., or nearly two-thirds, belongs to Kent. Of the total acreage in 1901, for example, 61·1 per cent. was returned by Kent, 14·7 by Hereford, 9·4 by Sussex, 7·9 by Worcester, 4·2 by Hants, 2·4 by Surrey, and the residual 0·3 per cent. jointly by Salop, Gloucester, and Suffolk. Arranging the counties in two geographical groups, it is found that 77·1 per cent. of the hop acreage of 1901 was in the south-eastern counties, and 22·9 per cent. in the west-midland counties.

Whilst the official figures concerning acreage are available as far back as the year 1868, those relating to production were not collected for the first time till 1885. The official estimators appointed for the purpose send in estimates of the total production of hops in their several districts, and these, divided by the number denoting the acreage cultivated, give the estimated average yield per acre. The home production of hops is always supplemented by imported produce, so that, in order to arrive at the actual quantities available for consumption, the two must be added together. These various details, as far back as the whole of the data are obtainable, form the subject of Table II. The quantities available for home consumption are not shown with complete accuracy in the last column of this table, as the exports have not been deducted. These, however, are relatively very small, and only amounted in 1901, for example, to 22,702 cwt., of which 17,796 cwt. were home-grown and 4906 cwt. imported. The wide fluctuations in the home production of hops are worthy of note, as they exercise a powerful influence upon market prices. The largest crop tabulated is that of 776,144 cwt. in 1886, and the smallest is that of

TABLE II.—*Acreage, Estimated Home Produce, and Imports of Hops into the United Kingdom in each Year, 1885 to 1901.*

Average, 17 years	57,228	478,850	8·40	192,555	671,405

281,291 cwt. in 1888, the former being more than $2\frac{1}{2}$ times the size of the latter. The crop of 1899, estimated at 661,373 cwt., was so large that prices receded to such an extent as to leave no margin of profit to the great body of growers, whilst some planters were able to market the crop only at a loss. The calculated annual average yields per acre over the seventeen years 1885 to 1901 are seen to range between 12·76 cwt. in 1899 and 4·81 cwt. in 1888, the former being 50 per cent. more and the latter nearly 50 per cent. less than the seventeen years' average of 8·4 cwt. No other staple crop of British agriculture undergoes such wide fluctuations in yield as are here indicated. How great may be the variation even in two consecutive years is shown in Table III., which sets out, county by

TABLE III.—*Estimated Total Produce of Hops in England in 1901 and in 1900.*

Total .	649,381	347,894	301,487	100·0	100·0

county, the estimated production in 1900 and 1901, and the percentage which the several counties contributed to each year's crop. As a matter of fact, the size of the crop produced bears no relation to the acreage under cultivation. For example, the 71,327 acres in 1885 produced only 509,170 cwt., whereas the 51,843 acres in 1899 produced 661,373 cwt.—19,484 acres less under crop yielded 152,203 cwt. more produce.

Comparing the quantities of home-grown hops with those of imported hops, the figures at the foot of Table II. indicate that, of the total available for consumption, about 70 per cent. on the average is home produce and about 30 per cent. is imported produce. The imports, however, do

not vary so much as the home produce. The latter has ranged between 776,144 cwt. in 1886 and 281,291 cwt. in 1888; whilst the highest and lowest imports were 266,952 cwt. in 1885 and 145,122 cwt. in 1887, the latter in the year following the biggest home-grown crop on record. Of the imports of 198,494 cwt. in 1900, as much as 147,378 cwt., or 73 per cent., came from the United States, where the crop is chiefly grown in the states of California, Oregon, Washington, and New York. Since 1895, however, the production in the last-named state has steadily declined, whilst the Pacific coast production has increased.

During the twenty years 1881–1900 the annual values of the hops imported into England fluctuated between the wide limits of £2,962,631 in 1882 and £427,753 in 1887. In five other years besides 1882 the value exceeded a million sterling, the amounts being £1,615,309 in 1884, £1,141,294 in 1893, £1,089,246 in 1883, £1,030,140 in 1898, and £1,001,728 in 1885. Next to 1887, the lowest annual sums were £447,253 in 1886, £524,297 in 1897, £591,582 in 1896, and £644,505 in 1895. The annual average value over the whole period was £944,062, whilst the annual average import was 200,562 cwt., consequently the average value per cwt. was £4 : 14s. The quantities and values of English-grown hops exported in the five years 1897 to 1901 were the following:—

Year.	Quantity. Cwt.	Value.
1897	10,779	£43,841
1898	12,955	71,321
1899	11,310	65,325
1900	14,999	63,526
1901	17,796	78,034

These figures represent an annual average export of 13,568 cwt., valued at £64,409, which is equivalent to £4 : 15s. per cwt. The quantities and values of the imported hops that are again exported are almost insignificant. Thus, in the three years 1899–1901 the re-exports were:—

	1899.	1900.	1901.
Quantity . .	3297 cwt.	3586 cwt.	4906 cwt.
Value . . .	£16,715	£10,005	£8305

Cultivation.

As the county of Kent has always taken the lead in hop-growing in England, and as it includes about two-thirds of the hop acreage of the British Isles, the recent developments in hop cultivation cannot be better studied than in that county. They have been well summarized by Mr Charles Whitehead in his sketch of the agriculture of Kent,[1] wherein he states that the hop grounds—or hop gardens, as they are called in Kent—of poor character and least suitable for hop production have been gradually grubbed since 1894, on account of large crops, the importation of hops, and low prices. At the beginning of the 19th century there were 290 parishes in Kent in which hops were cultivated. A century later, out of the 413 parishes in the county, as many as 331 included hop plantations. The hops grown in Kent are classified in the markets as "East Kents," "Bastard East Kents," "Mid Kents," and "Wealds," according to the district of the county in which they are produced. The relative values of these four divisions follow in the same order, East Kents making the highest and Wealds the lowest rates. These divisions agree in the main with those defined by geological formations. Thus, "East Kents" are grown upon the Chalk, and especially on the outcrop of the soils of the London Tertiaries upon the Chalk. "Bastard East Kents" are produced on alluvial soil and soils formed by admixtures of loam, clay loams, chalk, marl, and clay from the Gault, Greensand, and Chalk formations. "Mid Kents" are derived principally from the Greensand soils and outcrops of the London Tertiaries in the upper part of the district. "Wealds" come from soils on the Weald Clay, Hastings Sand, and Tunbridge Wells Sand. As each "pocket" of hops must be marked with the owner's name and the parish in which they were grown, buyers of hops can, without much trouble, ascertain from which of the four divisions hops come, especially if they have the map of the hop-growing parishes of England, which gives the name of each parish. There has been a considerable rearrangement of the hop plantations in Kent within recent years. Common varieties, as Colegate's, Jones's, Grapes, and Prolifics, have been grubbed, and Goldings, Bramlings, and other choice kinds planted in their places. The variety known as Fuggle's, a heavy-cropping though slightly coarse hop, has been much planted in the Weald of Kent, and in parts of Mid Kent where the soil is suitable. In very old hop gardens, where there has been no change of plant for fifty or even one hundred years in some instances, except from the gradual process of filling up the places of plants that have died, there has been replanting with better varieties and varieties ripening in more convenient succession; and, generally speaking, the plantations have been levelled up in this respect to suit the demand for bright hops of fine quality. A recent classification[2] of the varieties of English hops arranges them in three groups—(1) early varieties (*e.g.*, Prolific, Bramling, Amos's Early Bird); (2) mid-season or main-crop varieties (*e.g.*, Farnham Whitebine, Fuggle's, Old Jones's, Golding); (3) late varieties (*e.g.*, Grapes, Colgate's).

The cost of cultivating and preparing the produce of an acre of hop land tends to increase, on account of the advancing rates of wages, the intense cultivation more and more essential, and the necessity of freeing the plants from the persistent attacks of insects and fungi. In 1893 Mr Whitehead estimated the average annual cost of an acre of hop land to be £35 : 10s., the following being the items:—

	£	s.	d.
Manure (winter and summer)	£6	10	0
Digging	0	19	0
Dressing (or cutting)	0	6	0
Poling, tying, earthing, ladder-tying, stringing, lewing	2	3	0
Shimming, nidgeting, digging round and hoeing hills	3	0	0
Stacking, stripping, making bines, &c. . . .	0	17	0
Annual renewal of poles	2	10	0
Expense of picking, drying, packing, carriage, sampling, selling, &c., on average crop of, say, 7 cwt. per acre	10	5	0
Rent, rates, taxes, repairs of oast and tacks, interest on capital	6	0	0
Sulphuring	1	0	0
Washing (often two, three, or four times) . .	2	0	0
Total . . .	£35	10	0

Seven years later the average cost per acre in Kent had risen to quite £37.

The hops in Kent are usually planted in October or November, the plants being 6 feet apart each way, thus giving 1210 hills or plant-centres per acre. Some planters still grow potatoes or mangels between the rows the first year, as the plants do not bear much until the second year; but this is considered to be a mistake, as it encourages wire-worm and exhausts the ground. Many planters pole hop plants the first year with a single short pole, and stretch cocoanut-fibre string from pole to pole,

[1] *Jour. Roy. Agric. Soc.* 1899.

[2] J. Percival, "The Hop and its English Varieties," *Jour. Roy. Agric. Soc.* 1901.

and grow many hops in the first season. Much of the hop land is ploughed between the rows, as labour is scarce, and the spaces between are dug afterwards. It is far better to dig hop land if possible, the tool used being the Kent spud. The cost of digging an acre ranges from 18s. to 21s. Hop land is ploughed or dug between November and March. After this the plants are "dressed," which means that all the old bine ends are cut off with a sharp curved hop-knife, and the plant centres kept level with the ground.

Manuring.—Manure is applied in the winter, and dug or ploughed in. London manure from stables and cowhouses is used to an enormous extent. It comes by barge or rail, and is brought from the wharves and stations by traction engines; it costs from 7s. 6d. to 9s. per load. Rags, fur waste, sprats, wool waste, and shoddy are also put on in the winter. In the summer, rape dust, guano, nitrate of soda, and various patent hop manures are chopped in with the Canterbury hoe. Fish guano or desiccated fish is largely used; it is very stimulating, and more lasting than some of the other forcing manures.

The latest investigations into the subject of hop-manuring are those made by Dr Bernard Dyer and Mr F. W. E. Shrivell, at Golden Green, near Tonbridge, Kent. In the 1901 report [1] it is stated that the object in view is to ascertain how far nitrate of soda, in the presence of an abundant supply of phosphates and potash, is capable of being advantageously used as a source of nitrogenous food for hops. An idea long persisted among hop-growers that nitrate of soda was an unsafe manure for hops, being likely to produce rank growth of bine at the expense of quality and even quantity of hops. During recent years, however, owing very largely to the results of these experiments, and of corresponding experiments based upon these, which have been carried out abroad, hop farmers have much more freely availed themselves of the aid of this useful manure; and there is little doubt that the distrust of nitrate of soda as a hop manure which has existed in the past has been largely due to the fact that nitrate of soda, like many other nitrogenous manures, has often been misused (1) by being applied without a sufficient quantity of phosphates and potash, or (2) by being applied too abundantly, or (3) by being applied too late in the season, with the result of unduly delaying the ripening period. On most of the experimental plots nitrate of soda (in conjunction with phosphates and potash) has been used as the sole source of nitrogen; but it is, of course, not to be supposed that any hop-grower would use year after year, as is the case on some of the plots, nothing but phosphates, potash, and nitrate of soda. Miscellaneous feeding is probably good for plants as well as for animals, and there is a large variety of nitrogenous manures at the disposal of the hop-farmer, to say nothing of what, in its place, is one of the most valuable of all manures, namely, home-made dung. These experiments were begun in 1894 with a new garden of young Fuggle's hops. A series of experimental plots was marked out, each plot being one-sixth of an acre in area. The plots run parallel with one another, there being four rows of hills in each. The climate of the district is very dry.

The subjoined statement shows the annual yield of hops per acre on each plot, and also the average for each plot over the five years 1896–1900 :—

Weight of Kiln-dried Fuggle's Hops per Acre.

Plot.	Annual Manuring per Acre.	1896.	1897.	1898.	1899.	1900.	Average of 5 Years.
		Cwt.	Cwt.	Cwt.	Cwt.	Cwt.	Cwt.
A.	Phosphates and potash	13½	7½	8¼	20¼	8	11½
B.	Phosphates, potash, and 2 cwt. nitrate of soda	16½	9¼	10¼	22¼	9¾	13½
C.	Phosphates, potash, and 4 cwt. nitrate of soda	16½	12	12½	23	11	15
D.	Phosphates, potash, and 6 cwt. nitrate of soda	15¼	13	13	22½	10½	14¾
E.	Phosphates, potash, and 8 cwt. nitrate of soda	15	13½	15¼	23½	11	15½
F.	Phosphates, potash, and 10 cwt. nitrate of soda	15	13	15	24½	10½	15¾
X.	30 loads (about 15 tons) London dung	13	8	9¾	24½	10¾	13¾

In only one year did the very large dressing of 10 cwt. of nitrate of soda per acre afford any better result than was produced by the less heavy dressing of 8 cwt. per acre, and this was in 1899, a season of such abundance and such low prices that it may be regarded as an abnormal season. If the effect of this one season on the average be eliminated, the best results, as regards quantity, were obtained on plot E, receiving 8 cwt. of nitrate of soda per acre. But plot C, with 4 cwt. only of nitrate of soda per acre, has been on the average not more than ½ cwt. per acre behind plot E.

Valuations of the hops made by merchants and factors show that, on the whole, the market quality of the produce is very little affected by manuring. Moreover, chemical investigation of the hops appears to indicate that the brewing quality is not in any constant or definite way influenced by the manuring, except where the quantity of nitrate of soda has amounted to the large dressing of 8 cwt. or more per acre, a quantity which in some seasons would seem to have been prejudicial, although in one season it happened that the highest brewing value appertained to a sample grown with as much as 10 cwt. per acre.

The results of modern investigation show that it is very largely to the presence and proportion of soft resin that hops owe their preservative value, although the quality of hops is by no means wholly dependent on this one feature. The resin percentages in the samples grown on the several plots in 1898, 1899, and 1900 were the following :—

Plot.	Annual Manuring per Acre.	1898.		1899.		1900.	
		Total Resin.	Soft Resin.	Total Resin.	Soft Resin.	Total Resin.	Soft Resin.
		Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.
A.	Phosphates and potash	14·15	9·21	15·07	8·60	14·53	8·90
B.	Phosphates, potash, and 2 cwt. nitrate of soda	14·30	9·20	16·59	8·83	15·09	8·51
C.	Phosphates, potash, and 4 cwt. nitrate of soda	14·06	9·04	15·87	9·27	14·46	8·16
D.	Phosphates, potash, and 6 cwt. nitrate of soda	13·57	8·60	14·90	8·70	13·46	7·62
E.	Phosphates, potash, and 8 cwt. nitrate of soda	14·11	8·85	14·49	8·96	13·30	7·18
F.	Phosphates, potash, and 10 cwt. nitrate of soda	12·21	7·91	15·47	9·41	12·77	6·77
X.	30 loads (about 15 tons) London dung	13·93	8·66	14·92	8·80	14·78	9·07

The general results so far seem to show that the purchase of town dung for hops is not economical, unless under specially favourable terms as to cost of conveyance, and that it should certainly not be relied upon as a sufficient manure. Home-made dung is in quite a different position, as not only is it richer, but it costs nothing for railway carriage. As a source of nitrogenous manure, purchased

[1] *Six Years' Experiments on Hop Manuring.* London, 1901.

dung is on the whole too expensive. There is a large variety of other nitrogenous manures in the market besides nitrate of soda, such, for instance, as Peruvian and Damaraland guano, sulphate of ammonia, fish guano, dried blood, rape dust, furriers' refuse, horn shavings, hoof parings, wool dust, shoddy, &c. All of these may in turn be used for helping to maintain a stock of nitrogen in the soil; and the degree to which manures of this kind have been recently applied in any hop garden will influence the grower in deciding as to the quantity of nitrate of soda he should use in conjunction with them, and also to some extent in fixing the date of its application.

Dressings of 8 or 10 cwt. of nitrate of soda per acre, such as are applied annually to plots E and F, would be larger than would be put on where the land has been already dressed with dung or with other nitrogenous manures; and even, in the circumstances under notice, although these plots have on the average beaten the others in weight, the hops in some seasons have been distinctly coarser than those more moderately manured—though in the dry season of 1899 the most heavily dressed plot gave actually the best quality as well as the greatest quantity of produce.

With regard to the application of nitrate of soda in case the season should turn out to be wet, present experience indicates that, on a soil otherwise liberally manured, 4 cwt. of nitrate of soda per acre, applied not too late, would be a thoroughly safe dressing. In the case of neither dung nor any other nitrogenous fertilizers having been recently applied, there seems no reason for supposing that, even in a wet season, 6 cwt. of nitrate of soda per acre applied early would be otherwise than a safe dressing, considering both quantity and quality of produce. In conjunction with dung, or with the early use of other nitrogenous manures, such as fish guano, rape dust, &c., it would probably be wise not to exceed 4 cwt. of nitrate of soda per acre.

As to the date of application, April or May is the latest time at which nitrate of soda should, in most circumstances, be applied, and probably April is preferable to May. The quantity used should be applied in separate dressings of not more than 2 cwt. per acre each, put on at intervals of a month. Where the quantity of nitrate of soda used is large, and constitutes the whole of the nitrogenous manure employed, the first dressing may, on fairly deep and retentive soils, be given as early as January; or, if the quantity used is smaller, say in February; while February will, in most cases, probably be early enough for the first dressing in the case of lighter soils. The condition of the soil and the degree and distribution of rainfall during both the previous autumn and the winter, as well as in the spring itself, produce such varying conditions that it is almost impossible to frame general rules.

The commonly accepted notion that nitrate of soda is a manure which should be reserved for use during the later period of the growth of the bine appears to be erroneous. The summer months, when the growth of the bine is most active, are the months in which natural nitrification is going on in the soil, converting soil nitrogen and the nitrogen of dung, guano, fish, rape dust, shoddy, or other fertilizers into nitrates, and placing this nitrogen at the disposal of the plants; and it appears reasonable, therefore, to suppose that nitrate of soda will be most useful to the hops at the earlier stages of their growth, before the products of that nitrification become abundant. This would especially be so in a season immediately following a wet autumn and winter, which have the effect of washing away into the drains the residual nitrates not utilized by the previous crop.

The necessity, whether dung is used or not, and whatever form of nitrogenous manure is employed, of also supplying the hops with an abundance of phosphates, cannot be too strongly urged. The use of phosphates for hops was long neglected by hop-planters, and even now there are many growers who do not realize the full importance of heavy phosphatic manuring. On soils containing an abundance of lime, no better or cheaper phosphatic manure can be used than ordinary superphosphate, of which as much as 10 cwt. per acre may be applied without the slightest fear of harm. But if the soil is not decidedly calcareous—that is to say, if it does not effervesce when it is stirred up with some diluted hydrochloric (muriatic) acid—bone dust, phosphatic guano, or basic slag should be used as a source of phosphates, at the rate of not less than 10 cwt. per acre. On medium soils, which, without being distinctly calcareous, nevertheless contain a just appreciable quantity of carbonate of lime, it is probably a good plan to use the latter class of manures, alternately with superphosphate, year and year about; but it is wise policy to use phosphates *in some form or other* every year in every hop garden. They are inexpensive, and without them neither dung, nitrate of soda, ammonia salts, nor organic manures can be expected to produce both a full vigorous growth of bine and at the same time a well-matured crop of full-weighted, well-conditioned hops.

The use of potash salts, on most soils, is probably not needed when good dung is freely used; but where this is not the case it is safer in most seasons and on most soils to give a dressing of potash salts. On some soils their aid should on no account be dispensed with.

Experiments in hop-manuring have also, for some years past, been conducted in connexion with the South-Eastern Agricultural College, Wye, Kent. The main results have been to demonstrate the necessity of a liberal supply of phosphates, if the full benefit is to be reaped from applications of nitrogenous manure.

Tying, Poling, and Picking.—Tying the bines to the poles or strings is essentially women's work. It was formerly always piecework, each woman taking so many acres to tie, but it is found better to pay the women 1s. 8d. to 2s. per day, that they may all work together, and tie the plants in those grounds where they want tying at once. The new modes of poling and training hop plants have also altered the conditions of tying.

Many improvements have been made in the methods of poling and training hops. Formerly two or three poles were placed to each hop-hill or plant-centre in the spring, and removed in the winter, and this was the only mode of training. Recently systems of training on wires and strings fastened to permanent upright poles have been introduced. One arrangement of wires and strings much adopted consists of stout posts set at the end of every row of hop-hills and fastened with stays to keep them in place. At intervals in each row a thick pole is fixed. From post to post in the rows a wire is stretched at a height of half a foot from the ground, another about six feet from the ground, and another along the tops of the posts, so that there are three wires. Hooks are clipped on these wires at regular intervals, and cocoa-nut-fibre strings are threaded on them and fastened from wire to wire, and from post to post, to receive the hop-bines. The string is threaded on the hooks continuously, and is put on those of the top wire with a machine called a stringer. There are several methods of training hops with posts or stout poles, wire, and string, whose first cost varies from £20 to £40 per acre. The system is cheaper in the long run than that of taking down the poles every year, and the wind does not blow down the

poles or injure the hops by banging the poles together. In another method, extensively made use of in Kent and Sussex, stout posts are placed at the ends of each row of plants, and, at intervals where requisite, wires are fastened from top to top only of these posts, whilst cocoanut-fibre strings are fixed by pegs to the ground, close to each hop-stock, whence they radiate upwards for attachment to the wires stretching between the tops of the posts. This method is more simple and less expensive than the system first described, its cost being from £24 to £28 per acre. In this case the plants require to be well "lewed," or sheltered, as the strings being so light are blown about by the wind. These methods are being largely adopted, and, together with the practice of putting cocoanut-fibre strings from pole to pole in grounds poled in the old-fashioned manner, are important improvements in hop culture, which have tended to increase the production of hops. Where the old system of poling with two or three poles is still adhered to they are always creosoted, most growers having tanks for the purpose; and, in the new methods of poling, the posts and poles are creosoted, dipped, or kyanized.

At Wye College, Kent, previously mentioned, different systems of planting and training have been tried, the alleys varying in width from 10 feet down to 5 feet, and the distance between the hills varying quite as widely, so that the number of hills to the acre has ranged from 1210 down to 660. The biggest crop was secured on the plot where the hills were 8 feet apart each way. As a rule, indeed, a wide alley and abundant space between the plants, thus allowing the hops plenty of air and light, produced the best results, besides effecting some saving in the cost of cultivation, as there were only 660 or 680 hills per acre. Of the various methods of training, the umbrella system gave the biggest crop in each of the three years 1899, 1900, 1901; and it seemed to be the best method, except in seasons when washing was required early, in which case the plants were not so readily cleared of vermin.

Much attention is required to keep the bines in their places on the poles, strings, or wire, during the summer. This gives employment to many women, for whose service in this and fruit-picking there is considerable demand, and a woman has no trouble in earning from 1s. 6d. to 1s. 10d. per day from April till September at pleasant and not very arduous labour. The hop-picking follows, and at this women sometimes get 4s. and even 5s. per day. This is the real Kent harvest, which formerly lasted a month or five weeks. Now it rarely extends beyond eighteen days, as it is important to secure the hops before the weather and the aphides, which almost invariably swarm within the bracts of the cones, discolour them and spoil their sale, as brewers insist upon having bright, "coloury" hops. Picking is better done than was formerly the case. The hops are picked more singly, and with comparatively few leaves, and the pickers are of a somewhat better type than the rough hordes who formerly went into Kent for "hopping." Kent planters engage their pickers beforehand, and write to them, arranging the numbers required and the date of picking. Many families go into Kent for pea- and fruit-picking, and remain for hop-picking. Without this great immigration of persons, variously estimated at between 45,000 and 65,000, the crops of hops could not be picked; and fruit-farmers also would be unable to get their soft fruit gathered in time without the help of immigrant hands. The fruit-growers and hop-planters of Kent have greatly improved the accommodation for these immigrants.

Concerning the general question as to the advisability or otherwise of cutting the hop bine at the time of picking, Principal A. D. Hall, of Wye College, has ascertained experimentally that if the bine is cut close to the ground at a time when the whole plant is unripe there are removed in the bine and leaves considerable quantities of nitrogen, potash, and phosphoric acid which would have returned to the roots if the bine had not been cut until ripe. The plant, therefore, would retain a substantial store of these constituents for the following year's growth if the bine were left. Chemical analyses have shown that about 30 ℔ of nitrogen per acre may be saved by allowing the bines to remain uncut, this representing practically one-third of the total amount of nitrogen in the hops, leaf, and bine together. There are also from 25 ℔ to 30 ℔ of potash in the growth, of which nine-tenths would return to the roots, with about half the phosphoric acid and a very small proportion of the lime. It has been demonstrated that by the practice of cutting the bines when the hops are picked the succeeding crop is lessened to the extent of about one-tenth. As to stripping off the leaves and lower branches of the plant, it was found that this operation once reduced the crop 10 per cent. and once 20 per cent., but that in the year 1899 it did not affect the crop at all. The inference appears to be that when there is a good crop it is not reduced by stripping, but that when there is less vigour in the plant it suffers the more. Hence, it would seem advisable to study the plant itself in connexion with this matter, and to strip a little later, or somewhat less, than usual when the bine is not healthy.

Drying.—After being picked, the hops are taken in pokes—long sacks holding ten bushels—to the oasts to be dried. The oasts are circular or square kilns, or groups of kilns, wherein the green hops are laid upon floors covered with horsehair, under which are enclosed or open stoves or furnaces. The heat from these is evenly distributed among the hops above by draughts below and round them. This is the usual simple arrangement, but patent processes are adopted here and there, though they are by no means general. The hops are from nine to ten hours drying, after which they are taken off the kiln and allowed to cool somewhat, and are then packed tightly into "pockets" 6 feet long and 2 feet wide, weighing one and a half cwt., by means of a hop-pressing machine, which has cogs and wheels worked by hand. Of late years more care has been bestowed by some of the leading growers upon the drying of hops, so as to preserve their qualities and volatile essences, and to meet the altered requirements of brewers, who must have bright, well-managed hops for the production of light clear beers for quick draught. The use, for example, of exhaust fans, recently introduced, greatly facilitates drying by drawing a large volume of air through the hops; and as the temperature may at the same time be kept low, the risk of getting over-fired samples is considerably reduced, though not entirely obviated. The adoption of the roller floor is another great advance in the process of hop-drying, for this, used in conjunction with a raised platform for the men to stand on when turning, prevents any damage from the feet of the workmen, and reduces the loss of resin to a minimum. The best results are obtained when exhaust fans and the roller floor are associated together. In such cases the roller floor, which empties its load automatically, pours the hop cones into the receiving sheets in usually as whole and unbroken a condition as that in which they went on to the kiln.

Pests of the Hop Crop.—In recent years the difficulties attendant upon hop cultivation have been aggravated, and the expenses increased, by regularly recurring attacks of aphis blight—due to the insect *Aphis* (*Phorodon*) *humuli* —which render it necessary to spray or syringe every hop

plant, every branch and leaf, with insecticidal solutions three or four times, and sometimes more often, in each season. Quassia and soft-soap solutions are usually employed; they contain from 4 ℔ to 8 ℔ of soft soap, and the extract of from 8 ℔ to 10 ℔ of quassia chips to 100 gallons of water. The soft soap serves as a vehicle to retain the bitterness of the quassia upon the bines and leaves, making them repulsive to the aphides, which are thus starved out. Another pest, the red spider, *Tetranychus telarius*—really one of the "spinning mites"—is most destructive in very hot summers. Congregating on the under surfaces of the leaves, the red spiders exhaust the sap and cause the leaves to fall, producing the effect known in Germany as "fire-blast." The hop-wash of soft soap and quassia, so effective against aphis attack, is of little avail in the case of red spider. Some success, however, has attended the use of a solution containing 8 ℔ to 10 ℔ of soft soap to 100 gallons of water, with three pints of paraffin added. It is necessary to apply the washes with great force, in order to break through the webs with which the spiders protect themselves. Hop-washing is done by means of large garden engines worked by hand, but more frequently with horse engines. Resort is sometimes had to steam engines, which force the spraying solution along pipes laid between the rows of hops.

Mould or mildew is frequently the source of much loss to hop-planters. It is due to the action of the fungus *Podosphæra castagnei*, and the mischief is more especially that done to the cones. The only trustworthy remedy is sulphur, employed usually in the form of flowers of sulphur, from 40 ℔ to 60 ℔ per acre being applied at each sulphuring. The powder is distributed by means of a machine drawn by a horse between the rows. The sulphur is fed from a hopper into a blast-pipe, whence it is driven by a fan actuated by the travelling wheels, and falls as a dense, wide-spreading cloud upon the hop-bines. The first sulphuring takes place when the plants are fairly up the poles, and is repeated three or four weeks later; and even again if indications of mildew are present. It may be added that sulphur is also successfully employed in the form of an alkaline sulphide, such as solution of "liver of sulphur," a variety of potassium sulphide. (W. FR.)

Höritz (the "Oberammergau of the Bohemian Forest"), a commune in the district of Krumau in the Bohemian Forest, South Bohemia, Austria, noted for the periodical performances of passion-plays by the peasantry, which attract as many as 20,000 visitors. Population (1890), 1094; (1900), 1232, all German.

Hořitz, a town in the government district of Königgrätz, Bohemia, Austria. Sugar refining is now carried on, in addition to its older textile, brewing, and milling industries. It possesses a monument to Ziska, the Hussite leader, who obtained a victory over the Bohemian nobles here in 1423. Population (1890), 6910; (1900), 7771, all Czech.

Hornby, Sir Geoffrey Thomas Phipps (1825–1895), British admiral of the fleet, son of Admiral Sir Phipps Hornby, the first cousin and brother-in-law of the 13th Earl of Derby, by a daughter of Lieutenant-General Burgoyne, commonly distinguished as "Saratoga" Burgoyne, was born on 20th February 1825. At the age of twelve he was sent to sea in the flagship of Sir Robert Stopford, with whom he saw the capture of Acre in November 1840. He afterwards served in the flagship of Rear-Admiral Josceline Percy at the Cape of Good Hope, was flag-lieutenant to his father in the Pacific, and came home as a commander. When the Derby ministry fell in December 1852 young Hornby was promoted to be a captain. Early in 1853 he married, and as the Derby connexion put him out of favour with the Aberdeen ministry, and especially with Sir James Graham, the first lord of the Admiralty, he settled down in Sussex as manager of his father's property. He had no appointment in the navy till 1858, when he was sent out to China to take command of the *Tribune* frigate and convey a body of marines to Vancouver Island, where the dispute with the United States about the island of San Juan was threatening to become very bitter. As senior naval officer there Hornby's moderation, temper, and tact did much to smooth over matters, and a temporary arrangement for joint occupation of the island was concluded. He afterwards commanded the *Neptune* in the Mediterranean under Sir William Fanshawe Martin, was flag-captain to Rear-Admiral Dacres in the Channel, was commodore of the squadron on the west coast of Africa, and, being promoted to rear-admiral in January 1869, commanded the training squadron for a couple of years. He then commanded the Channel Fleet, and was for two years a junior lord of the Admiralty. It was early in 1877 that he went out as commander-in-chief in the Mediterranean, where his skill in manœuvring the fleet, his power as a disciplinarian, and the tact and determination with which he conducted the foreign relations at the time of the Russian advance on Constantinople, raised his reputation to a very great height and won for him the K.C.B. He returned home in 1880 with the character of being perhaps the most able commander on the active list of the navy. His later appointments were to the Royal Naval College as president, and afterwards to Portsmouth as commander-in-chief. On hauling down his flag he was appointed G.C.B., and in May 1888 was promoted to be admiral of the fleet. From 1886 he was principal naval aide-de-camp to Queen Victoria, and in that capacity, and as an admiral of the fleet, was appointed on the staff of the German Emperor during his visits to England in 1889 and 1890. He died, after a short illness, on 3rd March 1895. By his wife, who predeceased him, he left several children, daughters and sons, one of whom, a major in the artillery, won the Victoria Cross in South Africa in 1900. His life has been written by his daughter, Mrs Fred. Egerton. (J. K. L.)

Horncastle, a market town and railway station in the Horncastle parliamentary division of Lincolnshire, England, on the Bain and Waring, 21 miles east of Lincoln. There are large horse, cattle, and sheep markets. Area of parish (an urban district), 1421 acres. Population (1881), 4818; (1901), 4038.

Horne, Richard Hengist (1803–1884), English poet and critic, was born in London on New Year's Day 1803. He was intended for the army, and entered at Sandhurst, but receiving no commission, he left his country and joined the Mexican navy. He served in the war against Spain, and underwent many adventures. Returning to England, he started upon a literary career, and in 1836–37 edited *The Monthly Repository*. In the latter year he published two tragedies, *Cosmo de Medici* and *The Death of Marlowe*, and in 1841 a *History of Napoleon*. The book, however, by which he alone lives in memory is his epic of *Orion*, which appeared in 1843. It was published originally at a farthing, was widely read, and passed through many editions. In the next year he set forth a volume of critical essays called *A New Spirit of the Age*, in the composition of which he was assisted by his friend Elizabeth Barrett, with whom, from 1839 to her marriage in 1846, he conducted a voluminous correspondence. In 1852 he went to Australia in company with William Howitt, and was away from England for seventeen years. On his return in 1869

he continued an industrious literary career, but none of his later works can be considered important. He died at Margate 13th March 1884. Horne's extraordinary versatility resulted in a lack of concentration in performance: he was industrious and talented, but, except in the case of *Orion*, he never attained to a very high degree of distinction. That poem, indeed, has much of the quality of fine poetry; it is earnest, vivid, and alive with spirit. But Horne early drove his talent too hard, and continued to write when he had little left to say. In criticism he had insight and quickness. He was one of the first to appreciate Keats and Tennyson, and he gave valuable encouragement to Elizabeth Barrett. His old age was rich in memories of the beginnings of the leading spirits of Victorian poetry. (A. WA.)

Hornellsville, a city of Steuben county, New York, U.S.A., on the river Canisteo, at an altitude of 1161 feet. It is on the Erie and the Pittsburg, Shawmut and Northern Railways. The car works of the Erie Railway are located here. Population (1880), 8195; (1890), 10,996; (1900), 11,918, of whom 1230 were foreign-born.

Horodenka, a district town and manufacturing centre in eastern Galicia, on a southern tributary of the Dniester. It has considerable corn trade, and manufacture of soap, candles, potash, &c. Population, chiefly Ruthenians (1890), 11,162; (1900), 11,615.

Hořowitz, the chief town of a government district in West Bohemia, Austria, a station on the railway between Prague and Pilsen. It has manufactures of enamelled wares and matches, corn-milling and brewing. Population, Czech (1900), 3570.

Horse-breeding. See AGRICULTURE.

Horse-racing.—GREAT BRITAIN. Horse-racing, usually described as "the national sport," has greatly advanced in general popularity. The effect of this is not wholly satisfactory, because of the large amount of gambling thus encouraged, with its inevitable evils; but there is no doubt that the best specimens of the English thoroughbred horse are the finest animals of their kind in existence. The value of an infusion of the blood for chargers, hunters, hacks, and other varieties is scarcely to be overestimated; and the only way of ascertaining what animals may be most judiciously employed for breeding purposes is to submit them to the tests of preparation for and performance on the Turf. Racing is therefore a practical necessity. On some accepted authority, the origin of which is not to be traced, five races run each season by three-year-olds are distinguished as "classic." Of these the chief, by universal consent, is the Derby, which takes place at Epsom during the week which includes the 31st May. The Epsom course, on which the Derby has been run since its origin in 1780, is by no means a good one, in consequence of the abrupt turn at Tattenham Corner; and the severe descent after this turn is made is also held to be a disadvantage, though a really good horse should be able to act on ascents, descents, and level ground with equal facility. In many respects the St Leger, run at Doncaster about the middle of September, is a better test, as here colts and fillies meet when both are presumably able to do themselves the fullest justice. September, indeed, has been called "the Mares' Month," for though fillies are eligible to run in the Derby, they are very frequently out of sorts and always more or less uncertain in their performances during the summer—only three have been successful in 121 contests for the stake—whereas in the autumn their numerous victories in the St Leger prove them to be at their best.

Classic races in England.

During the period 1884–94 fillies, who now carry 3 lb less than colts, won the St Leger on twelve occasions—an undue proportion, as not 15 per cent. of the runners were mares,—and it was the recognition of this fact which induced an alteration of the weights in the year 1882, previously to which fillies had carried 5 lb less than colts. The Doncaster course is superior for racing purposes to that at Epsom, where the Oaks, another of the "classic races," is run on the Friday following the Derby; the other two contests which come into this category being the Two Thousand Guineas for colts and fillies, and the One Thousand Guineas for fillies only. These races take place at Newmarket during the First Spring Meeting, the former always on a Wednesday, the latter on Friday. The expression "a Derby horse" is common, but has no precise significance, as the three-year-olds vary much in capacity from year to year. It is generally understood, for instance, that Ormonde, who won the Derby in 1886, must have been at least 2 stone superior to Sir Visto or Jeddah, who were successful in 1895 and 1898. By their ability to carry weight the value of horses is estimated on the Turf. Thus one horse which beats another by a length over a distance of a mile would be described as a 5-lb better animal.

The term "handicap horse" once had a significance which it does not now possess. In handicaps horses carry weight according to their presumed capacity, as calculated by handicappers who are licensed by the Jockey Club and employed by the directors of different meetings. The idea of a handicap is to afford chances of success to animals which would have no prospect of winning if they met their rivals on equal terms; but of late years the value of handicaps has been so greatly increased that few owners resist the temptation of taking part in them. Horses nowadays which do not run in this kind of contest are very rare, though a few, such as Ormonde, Isinglass, and Persimmon, never condescended to what may be regarded as an inferior class of sport. The late duke of Westminster did not hesitate to put his Derby winner Bend Or into some of the chief handicaps; and it is, of course, a great test of merit when horses run in these contests, and, carrying heavy weights, show marked superiority to rivals of good reputation more lightly burdened. St Gatien, who won the Derby in 1884; Robert the Devil, who won the St Leger in 1880 and on several occasions beat the Derby winner Bend Or; and La Flèche, who won the Oaks and the St Leger in 1892, added to the esteem in which they were held by their successes under heavy weights, the colts in the Cesarewitch, the filly in the Cambridgeshire. Of the chief handicaps of the year, special mention may be made of the City and Suburban, run at the Epsom Spring Meeting over a mile and a quarter; the Kempton Park Jubilee, over a mile; the Ascot Stakes, two miles, and the Royal Hunt Cup, one mile; the Stewards' Cup at Goodwood, six furlongs; the Cesarewitch Stakes and the Cambridgeshire Stakes at Newmarket, the former two miles and a quarter, the latter 2000 yards, otherwise described as "a mile and a distance"—a distance on the Turf being a fixed limit of 240 yards. The cups at Manchester and Liverpool are also handicaps of some note, though it may be remarked that the expression "a cup horse" is understood to imply an animal capable of distinguishing himself over a long distance at even weights against the best opponents. There are many other valuable stakes of almost equal importance, diminishing to what are known as "selling handicaps," the winners of which are always put up for sale by auction immediately after the race, in the lowest class of them the condition being that the winner is to be offered for £50. No stake

Handicap horses.

Park, where Memoir, La Flèche, Best Man, and other good animals were bred, has now been abandoned.

Trainers and jockeys. In many cases trainers have graduated from jockeys. The usual charge to an owner is 50s. a week per horse, but, as regards the cost of a horse in training, to this there are various additions irrespective of entrances to races, forfeits, travelling, jockeys' fees, &c. The recognized sum paid to a jockey is 3 guineas for a losing mount, 5 guineas for winning. In many cases special terms are made; the principal owners usually have a claim on a rider's services, and for this call as much as £5000 per annum, exclusive of the usual riding fees, has been given.

From time immemorial until within a very recent period jockeys rode in much the same style, though, of course, with varying degrees of skill. Many hundreds of boys exercise daily at Newmarket and other training grounds, all of them necessarily having a tight seat in the saddle, for the thoroughbred horse is, as a rule, high-couraged and apt to play violent tricks; but though most of these lads find chances to distinguish themselves in trials and races for apprentices, probably not five per cent. grow into professional jockeys, increasing weight keeping many from the business, as a jockey has few chances unless he can ride well under 9 stone. Knowledge of pace is a rare gift or acquisition which is essential to successful jockeyship. The rider must also be quick to perceive how his own horse is going—what he has "left in him"; he must understand at a glance which of his rivals are beaten and which are still likely to be dangerous; must know when the moment comes for the supreme effort to be made, and how to balance and prepare the horse for that critical struggle. At the beginning of the race the jockey used to stand in his stirrups, with the idea of removing weight from the horse's back and preserving perfect steadiness; towards the end of the race, if it were necessary to drive the animal home, he sat down "to finish."

This method used to be adopted in all countries, but recently a new system came into practice in America. Instead of putting the saddle in the middle of the horse's back, where it had always been placed previously, it was shifted forward on to the animal's withers. The jockey rode with very short stirrups, leaning forward over the neck and grasping the reins within a few inches of the horse's mouth. The appearance of this was ungainly in the extreme and an entire departure from ancient ways (though Fordham and a few other riders of great reputation had always sat much more forward than their contemporaries), but it was found to be remarkably effective. From the position thus adopted there was less resistance to the wind, and though the saving in this respect was largely exaggerated, in racing, where success or failure is frequently a matter of a very few inches, every little that helps is to be considered. The value of the discovery lay almost entirely in the fact that the horse carries weight better—and is therefore able to stride out more freely—when it is placed well forward on his shoulders. With characteristic conservatism the English were slow to accept the new plan. Several American jockeys, however, came to England. In all the main attributes of horsemanship there was no reason to believe that they were in the least superior to English jockeys, but their constant successes required explanation, and the only way to account for them appeared to be that horses derived a marked advantage from the new system of saddling. A number of English riders followed the American lead, and those that did so met with an unusual degree of success. Race-riding, indeed, was in a very great measure revolutionized in the closing years of the 19th century.

Foreign horses. In the ninth edition of the *Encyclopædia Britannica* it was noted of American horses that "on the whole they have not been very successful." This can be said no longer. Of late years American horses—bred, it must always be remembered, from stock imported from England—have won many races in England. Australian horses have also been sent to the mother country, with results remunerative to their owners, and the intermixture of blood which will necessarily result should have beneficial consequences. French horses—*i.e.*, horses bred in France from immediate or from more or less remote English parentage—have also on various occasions distinguished themselves on English racecourses. That coveted trophy, the Ascot Cup, was won by a French horse, Elf II., in 1898, it having fallen also to the French-bred Verneuil in 1878, to Boiard in 1874, to Henry in 1872, and to Mortemer in 1871. In the Cesarewitch Plaisanterie (3 yrs., 7 st. 8 ℔) and Ténébreuse (4 yrs., 8 st. 12 ℔) were successful in 1885 and 1888; and Plaisanterie also carried off the Cambridgeshire as a three-year-old with the heavy weight of 8 st. 12 ℔ in a field of 27 runners. In not a few respects racing in France is conducted with praiseworthy discrimination. There are scarcely any of the five- and six-furlong scrambles for horses over two years old which are such common features of English programmes.

Time. That the horses which have covered various distances in the shortest times on record must have been exceptionally speedy animals is obvious. The times of races, however, frequently form a most deceptive basis in any attempt to gauge the relative capacity of horses. A good animal will often win a race in bad time, for the reason that his opponents are unable to make him exert himself to the utmost. Not seldom a race is described as having been "won in a canter," and this necessarily signifies that if the winner had been pressed to gallop he would have completed the course more quickly. The following figures (from the *Sportsman*) show the shortest times that have been occupied in winning over various distances:—

		M.	S.
One mile	*a*Caiman	1	33⅕
Rowley Mile (1 m. 11 yds.)	*b*Galtee More	1	40⅗
One mile and a quarter	*c*Fancy Man	2	3⅕
One mile and a half	*d*Volodyovski	2	40⅘
,,	*e*Memoir	2	40⅘
,,	*f*Bend Or	2	40
,,	*g*Landrail	2	34
,,	*h*Carbiston	2	37⅖
,,	*i*Santoi	2	31
,,	*j*Avidity	2	30⅘
,,	*k*King's Courier	2	31⅖
One mile and three-quarters	*l*Florizel II	2	59⅕
Five furlongs	*m*Othery	0	57⅕
Six furlongs	*n*Master Willie	1	7⅛
One mile and three furlongs	*o*Fatherless	2	19⅖

a, At Lingfield, 13th July 1900. *b*, Two Thousand. Previous fastest, 1 min. 42⅕ secs. by Marco in Payne Stakes, Newmarket, 16th May 1895; 1 min. 42⅖ secs. by Kirkconnel and Isinglass; and 1 min. 42⅘ secs. by Amphion, who carried 10 st. 1 ℔, in the March Stakes in 1891. *c*, At Manchester, in Prince Edward Handicap, 28th September 1901. *d*, The Derby, 1901. *e*, The Oaks, 1890. *f*, At Epsom, in the Gold Cup, 1881. *g*, At Doncaster, 8th September 1899. *h*, At York, in Duke of York Stakes, 23rd August 1899. *i*, At Hurst Park, in Great Whitsuntide Handicap, 27th May 1901. *j*, At Doncaster, in Alexandra Plate, 13th September 1900. *k*, At Hurst Park, in September Handicap, 22nd September 1900. *l*, At Manchester, in the Cup, 7th June 1895. *m*, At Epsom, 19th April 1898. *n*, At Epsom, in Royal Stakes, 6th June 1901. *o*, At Nottingham, 1st October 1895.

As regards time in famous races, Ormonde, perhaps the best horse of the 19th century—one, at any rate, that can scarcely have had a superior—occupied 2 minutes 45⅗ seconds in winning the Derby; and Lonely, one of the worst mares that have won the Oaks, galloped the same mile and a half in 2 seconds less. Ormonde's St Leger time was 3 m. 21⅗ s., and Sir Visto, probably the poorest specimen of a winner of the great

Doncaster race, took 3 m. $18\frac{2}{5}$ s. Weight "brings horses together," as the phrase runs—that is to say, equalizes their chances; hence handicaps, the carrying of penalties by winners, and "maiden allowances": a horse that has never won, and is therefore known as a "maiden," often has an allowance of 7 lb.

Sport is carried on under the auspices of the Jockey Club, a self-elected body of the highest standing, whose powers are absolute and whose sway is judicious and beneficent. Three stewards, one of whom retires each year, when a successor is nominated, govern the active—and extremely arduous—work of the Club. They grant licenses to trainers and jockeys and all officials, and supervise the whole business of racing. The stewards of the Jockey Club are *ex officio* stewards of Ascot, Epsom, Goodwood, and Doncaster. All other meetings are controlled by stewards, usually well-known patrons of the Turf invited to act by the projectors of the fixture, who settle disputed points, hear and adjudicate on objections, &c., and, if special difficulties arise, report to the stewards of the Jockey Club, whose decision is final.

The Jockey Club.

Steeplechasing. — Steeplechasing has altered entirely since the first introduction of this essentially British sport. In early days men were accustomed to match their hunters against each other and ride across country to a fixed point near to some steeple which guided them on their way; and this is no doubt, in several respects, a class of sport superior to that now practised under the name of steeplechasing; for it tested the capacity of the horse to jump fences of all descriptions, and provided the rider with opportunities of showing his readiness and skill in picking the best line of country. But racing of this kind afforded spectators a very small chance of watching the struggle; and made-up steeplechase courses, the whole circuit of which could be viewed from the enclosures, came into existence. The steeplechase horse has also changed. The speed of the thoroughbred is so much greater than that of all other breeds that if one were in the field, if he only stood up and could jump a little, his success was certain; consequently, except in "point-to-point" races, organized by various hunts, where a qualification is that all starters must have been regularly ridden with hounds, none other than thoroughbred horses are nowadays ever found in races run under the rules of the National Hunt Committee, the body which governs the sport of steeplechasing. A considerable proportion of existing steeplechase horses have done duty on the flat. Members of certain equine families display a special aptitude for jumping; thus the descendants of Hermit, who won the Derby in 1867, are very frequently successful in steeplechases—Hermit's son Ascetic, the sire of Cloister, Hidden Mystery, and other good winners, is a notable case in point. The sons and daughters of Timothy and of several other Hermit horses often jump well. When a flat-race horse appears to have comparatively poor prospects of winning under Jockey Club rules, he is frequently, if he "looks like jumping," schooled for chasing, usually in the first place over hurdles, and subsequently over what is technically called "a country," beginning with small fences, over which he canters, led by some steady animal who is to be depended on to show the way. A great many steeplechase horses also come from Ireland. They are usually recognizable as thoroughbred, though it is possible that in some cases the name of an ancestor may be missing from the Stud Book. Irish horse-masters are for the most part particularly skilful in schooling jumpers, and the grass and climate of Ireland appear to have beneficial effects on young stock; but as a rule the imported Irish horse improves considerably in an English training-stable, where he is better fed and groomed than in most Irish establishments. All steeplechase courses must at the present time contain certain regulation jumps, the nature of which is specified in the National Hunt rules:—

Steeple-chase horses.

44. In all steeplechase courses there shall be at least twelve fences (exclusive of hurdles) in the first 2 miles, and at least six fences in each succeeding mile. There shall be a water jump at least 12 feet wide and 2 feet deep, to be left open, or guarded only by a perpendicular fence not exceeding 2 feet in height. There shall be in each mile at least one ditch 6 feet wide and 3 feet deep on the taking-off side of the fence, which ditch may be guarded by a single rail, or left open, and which fence must be 4 feet 6 inches in height, and, if of dead brushwood or gorse, 2 feet in width.

45. In all hurdle-race courses there shall be not less than eight flights of hurdles in the first 2 miles, with an additional flight of hurdles for every quarter of a mile or part of one beyond that distance, the height of the hurdles being not less than 3 feet 6 inches from the bottom bar to the top bar.

Natural fences would no doubt be desirable if they could be utilized; but it is obvious that fences must be made up, because when the same hedge is jumped frequently, and for the most part in the same place —as it is the object of riders to go the shortest way round—gaps would necessarily be made. The use of these made courses naturally renders the sport somewhat artificial, but under existing conditions this is unavoidable; and as a matter of fact, by reason of the conformation of the ground, the arrangement and make of the fences, courses do vary in no small degree. The steeplechase horse differs from the hunter in his method of jumping. In riding to hounds a man usually steadies his horse at a fence, and in almost every case the animal "dwells" more or less after the leap. In a steeplechase, where speed is everything, horses must be taught to dash resolutely at their jumps without hesitation, and to get away with no pause on the other side; as a rule, therefore, an old steeplechase horse who is employed as a hunter is rarely a pleasant mount for any but a bold rider. It has been remarked that steeplechase horses are usually in the first place schooled over hurdles, and many animals remain hurdle racers till the end. More speed is required for hurdles than for a steeplechase course, and there is more money to be won over hurdles than over "a country." No hurdle race is worth so much as the Grand National or the Lancashire Handicap Steeplechase, the two richest prizes now offered; but, with the exception of these, hurdle-race stakes are as a rule of greater value. Except as a spectacle, there is little to be said in defence of this mongrel business, which is neither one thing nor the other; but hurdle races are popular, and are therefore likely to continue. A few years ago an attempt was made to discriminate between what were called "hunters" and handicap steeplechase horses, and certain races were only open to the former class. It proved, however, to be a distinction without a difference; thoroughbred horses crept into the ranks of the so-called hunters, and when nominal hunters began to be entered for, and in some cases to win, the Grand National and other important steeplechases, for which they could be nominated by abandoning their qualification of hunter, the meaningless title was relinquished. Still more absurd were the hunters' flat races of a former day. In order to compete in these the rule was that an owner must produce a certificate from a master of hounds to the effect that his horse had been hunted. Thoroughbreds who lacked speed to win under Jockey Club rules used to be ridden to a meet, perhaps cantered across a field or two, and were then supposed to have become hunters. Animals which were genuinely and regularly utilized for the pursuit of foxes had of course no chance against these race-horses in shallow disguise. What are called National Hunt flat races still exist, the qualifica-

Jumping.

Hunters and steeple-chase horses.

tion being that a horse must have been placed first, second, or third in a steeplechase in Great Britain or Ireland, after having jumped all the fences and completed the whole distance of the race to the satisfaction of at least two of the stewards, to whom previous notice must have been given in writing. There are no handicaps for such animals, and none is allowed to carry less than 11 stone. No race under National Hunt rules can be of a shorter distance than 2 miles, and the lowest weight carried can never be less than 10 stone except in a handicap steeplechase of 3½ miles or upwards, when the lowest weight may be 9 st. 7 lb.

Riders.

Horses are ridden in these races either by gentlemen, or qualified riders, or jockeys. The first of these classes comprises officers on full pay in the army or navy, persons holding commissions under the Crown, bearing titles either in their own right or by courtesy, or members of certain social and racing clubs. Qualified riders may be farmers holding at least a hundred acres of land, their sons if following the same occupation, and persons elected by members of the National Hunt Committee, a proviso being that they must never have ridden for hire, but it is feared that this rule is in not a few cases evaded. Professional jockeys are paid £5 for each mount, or £10 if they win. The sport is governed by the National Hunt Committee, a body which receives delegated powers from the Jockey Club, and six stewards are elected every year to supervise the business of the various meetings. Steeplechases and hurdle races are either handicaps or weight-for-age races according to the following scale :—

For Steeplechases of 3 miles and upwards.

From the 1st of January to the 30th of June, both inclusive :—

4 yrs.	5 yrs.	6 and aged
10 st. 3 lb	11 st. 8 lb	12 st. 3 lb

From the 1st of July to the 31st of December, both inclusive :—

4 yrs.	5 yrs.	6 and aged
11 st.	11 st. 12 lb	12 st. 3 lb

For Steeplechases of less than 3 miles.

From the 1st of January to the 30th of June, both inclusive :—

4 yrs.	5 yrs.	6 and aged
10 st. 10 lb	11 st. 10 lb	12 st. 3 lb

From the 1st of July to the 31st of December, both inclusive :—

4 yrs.	5 yrs.	6 and aged
11 st. 6 lb	12 st.	12 st. 3 lb

For Hurdle Races.

From the 1st of January to the 31st of August, inclusive :—

4 yrs.	5 yrs.	6 and aged
11 st. 6 lb	11 st. 10 lb	12 st. 0 lb

From the 1st of September to the 31st of December, inclusive :—

3 yrs.	4 yrs.	5, 6, and aged
10 st. 7 lb	11 st. 12 lb	12 st. 3 lb

The Grand National.

The great test of merit in a steeplechase horse is success in the Grand National, which is always run at Liverpool during the first week of the flat-racing season. The course is 4½ miles, and includes thirty jumps, the fences being for the most part larger than are found elsewhere. The average time occupied is about ten minutes. The stake has varied in value since the race was originated in 1839; it now amounts to close on £2000. Only a very small percentage of steeplechase horses possess the speed and staying power to give them a chance in this race, and the number of entries year by year falls considerably short of a hundred, the prospects of many of these usually appearing hopeless to all but unduly sanguine owners. The average number of starters during the period 1860–1901 was rather over twenty. As many as thirty competed in 1866, when Salamander won; in 1883, when Zoedone, ridden by her owner, Count Kinsky, was successful, only ten went to the post. Mishaps are almost invariably numerous; in 1890, of sixteen starters no fewer than eleven fell. So severe is the task that for a long time many good judges of steeplechasing believed that no horse with more than 12 stone on his back could possibly win. In 1893, however, Cloister won in a canter by forty lengths carrying 12 st. 7 lb, and with the same weight Manifesto also won in 1899. The race which most nearly approaches the Grand National in importance is the Lancashire Handicap Steeplechase, run at Manchester over 3½ miles early in April. The stake is worth about £1750. An interesting steeplechase called the Grand Sefton takes place at Liverpool about the middle of November; the distance is 3 miles. During the winter, and extending into the spring, steeplechasing and hurdle racing are carried on at Sandown, Kempton, Gatwick, Lingfield, and Hurst Park; at Ludlow, Newmarket, Aldershot, Birmingham, Manchester, Windsor, and other places. A race called the National Hunt Steeplechase, under the immediate patronage of the National Hunt Committee, takes place annually; it is run over a 4-mile course, the stake being £1000. Managers of various courses bid for the privilege of having the race on their ground, and it is therefore run in different localities. A condition is that no horse who has ever won a race can compete; and, as few owners are willing to keep their animals with a view to success in this event, the field consists either of unknown horses or of those that have been beaten.

Australia.—Racing in Australia has its headquarters at Sydney, under the government of the Australian Jockey Club, the principal course being at Ranwick; and at Melbourne, where the Victoria Jockey Club is supreme, the principal course being at Flemington. In New Zealand sport is carried on under the authority of delegates from the chief racing clubs, who meet in conference. There is a Sydney Derby and a Victoria Derby, and a notable event at Flemington is the Champion Race, weight-for-age, for three-year-olds and upwards, which usually attracts the best horses in training, as the fee at which a sire stands depends in a great measure on his success in this contest. This race is over a distance of 3 miles, and to ensure a good pace there is a regulation that the time in which it is run must not exceed 5 minutes 40 seconds, though the stewards have power to extend this in case the ground should be made exceptionally heavy by rainy weather. The Melbourne Cup is regarded as one of the most important races in the state. This is a handicap, and in comparison with English races may perhaps be ranked with the Cesarewitch. The birth of horses dates from the 1st of August, which corresponds as nearly as possible to the 1st of February in England, so that the Australian horses are practically seven months younger than the English—a matter of some importance in the case of those sent to run in England. There are few races which close long before the date of decision, and practically all the good animals run in handicaps. The five- and six-furlong races for other than two-year-olds, so common in Great Britain, are extremely rare; and it is asserted by colonial sportsmen that their horses stay better than those bred in England, a circumstance which is largely attributed to the fact that mares and foals have much more liberty and exercise than is the case in the mother country. Horses brought to England from the colonies have certainly had a considerable share of success in recent years, though of course it must be assumed that only specially good ones, which have seemed likely to distinguish themselves, have been sent. The chief courses are carefully tended, the crowd not being permitted to stray upon them, and some distance from the members' stands is erected what is called a "silence post," beyond which the bookmakers are not

allowed to ply their calling. An electric timing clock is fixed on the judge's box, set in motion when the starter's flag falls, and stopped as the winner passes the post, for the edification of those who wish to know the precise duration of the contest. The steeplechase and flat racecourses run side by side at Ranwick and at most other places, separated by double rails, between which police patrol. The outer rail leans towards the horses, and is so shaped that a jockey can hardly meet with injury by having his leg crushed against it, and the steeplechase fences are high and strong; indeed, their strength is so considerable that many spectators are in the habit of sitting on them to watch the flat racing. Logs, palings, posts and rails, and other severe jumps occur, and as the going is usually very hard, falls are frequently attended by serious consequences.

Canada.—Canada is independent, and the racing there is in a very heterogeneous condition, though the Ontario Jockey Club leads the way and gives an excellent meeting every spring at Toronto.

United States.—Racing in the United States, though in a transitory condition, has gradually been assuming definite and coherent form. Owing to the vast size of the country, there are various centres of sport, which can be classified with reasonable accuracy as follows:—the Eastern States, dominated by the Jockey Club, founded in New York in 1894, and recognized by a state law in 1895; the Middle Western States, under the control of the Western Jockey Club, whose headquarters are in Chicago; the Pacific Coast, with San Francisco for its centre; and the Southern and South-Western States, with Louisville as the most important centre. The passage of the racing law in New York State marked the opening of a new era. Supreme even over the Jockey Club is a State Racing Commission of three, appointed by the governor of the state. While the Jockey Club is only recognized by law in its native state, it has assumed and maintains control of all racing on the eastern seaboard, within certain lines of latitude and longitude, extending as far north as the Canadian border and south to Georgia. There is small question that other states, both east and west, will follow suit and enact similar laws. The Western Jockey Club, though not recognized by law, controls practically all the racing through the middle west, south-west, and south; but the racing associations of the Pacific Coast have maintained a position of independence.

What New York is to the east, Chicago is to the middle west, and a very large proportion of American racing is conducted close to these centres. In New York State the Coney Island Jockey Club, at Sheepshead Bay; the Brooklyn Jockey Club, at Gravesend; the Westchester Racing Association, at Morris Park; the Brighton Beach Racing Association, at Brighton Beach; the Queen's County Jockey Club, at Aqueduct; and the Saratoga Racing Association, at Saratoga, are the leading organizations; and all these racecourses, with the exception of Saratoga, are within a radius of 20 miles of the city. The Empire City Jockey Club, near Yonkers, and a new club with headquarters near Jamaica, Long Island, are likely to be prominent in the near future. The Washington Park Club, at Chicago, is the leading Turf body of the West, and the only one on an equal footing with the prominent associations of New York State. With this single exception the most important and valuable stakes of the American Turf are given in the East; and so great has the prosperity of the Turf been since the Jockey Club came into existence, that the list of rich prizes is growing at a surprising rate. In this respect the principal fault is the undue encouragement given to the racing of two-year-olds. At the winter meetings held at New Orleans and San Francisco, two-year-olds are raced from the very beginning of the year; and under the rules of the Jockey Club of New York they run as early as March. The Westchester Racing Association, with which are closely identified some of the principal members of the Jockey Club, gives valuable two-year-old stakes in May. The Futurity Stakes, the richest event of the year—on one occasion it reached a value of $67,675—is for two-year-olds, and is run at Sheepshead Bay in the autumn. The institution of races, either absolutely or practically at weight-for-age, and over long courses, has engaged much attention. The Coney Island Jockey Club has the leading three-year-old stake in the Lawrence Realization, over 1 mile 5 furlongs, with an average value of about $30,000. The Westchester Racing Association's two principal three-year-old stakes, the Withers, over a mile, run in May, and the Belmont, 1 mile and 3 furlongs, run later in the same month, are of less value, but are much older-established and have a species of "classic" prestige, dating from the old Jerome Park racecourse in the 'sixties. The Coney Island Jockey Club's Century and the Annual Champion Stakes, both for three-year-olds and upwards, over a mile and a half and two miles and a quarter respectively, are fair specimens of the races the associations are now founding. At Saratoga a stake of $50,000 for three-year-olds and upwards, distance a mile and a quarter, has been opened, to be run for first in 1904. The hope is to wean owners from the practice of overtaxing their two-year-olds, which has resulted practically in a positive dearth, almost a total absence, of good four-year-olds and upward of late years. Handicaps play a more important part than in England. The principal events of this character, such as the Brooklyn Handicap at Gravesend and the Suburban at Sheepshead Bay, have for years drawn the largest attendances of the racing season.

Practically all flat racing in the United States is held on "dirt-tracks," *i.e.*, courses with soil specially prepared for racing, instead of turf courses. At Sheepshead Bay there is a turf course, but it is only used for a minority of races. Dirt-tracks, which are, like many other things in American racing, a legacy from the once hugely popular harness-racing, are conducive to great speed, but are costly in the extreme strain on horses' legs. Steeplechases are run on turf. This branch of the sport in the East is now flourishing under the administration of the National Steeplechase and Hunt Association, a sister body of the Jockey Club. Comparatively few races are, however, run under these rules, as the weather conditions render it impossible to have a separate season for cross-country sport and steeplechases, and hurdle races are incorporated in programmes of flat racing held through the spring, summer, and autumn, though the ground is frequently so hard as to be unsafe. Since the National Steeplechase and Hunt Association assumed control, regulation courses, practically similar in every respect to those used in England, have been insisted upon in the East, the "open ditch" figuring under the name of the "Liverpool." In the West and South there is not the same uniformity, and so far the sport has not flourished.

The American thoroughbred blood of to-day, of course, originally came from England. Unfortunately but little is known of what was done in the way of racing in the colonial days, and the present era can only be traced practically back to the importation into Virginia of Diomed, winner of the first English Derby. In spite of his advanced age, he was a prolific stock-getter, and the old American pedigrees abound in his name, his descendants being inbred continuously. Since Diomed's day the importation of English stock has been constant. St Blaise, another Derby winner, had a brilliant success for a while,

but failed later in other hands when mated with mares of less fashionable family. Ormonde, bought for $150,000 to go to California, was a total failure; but prior to these horses were many that built the American thoroughbred up to his present standard. Leamington was sent to America to race, but at the stud won undying fame, his blood "nicking" exactly with that of the American Lexington. Then there was Glenelg, the horse whose gameness until death "The Druid" told. His stock, in the female line especially, are invaluable. The French horses, Mortemer and Rayon d'Or, ended their days in the United States, and the former did grand service. From Australia Sir Modred, Darebin, Maxim, Cheviot, and others came, especially to California. The recruits drawn from England have been practically numberless. Blue Gown, Ossory, and some more died on the way; but American pedigrees are full of imported horses. Buckden was one of the comparatively early importations, and left a great mark. Galore, Meddler, and Atheling are among the later, and Meddler promises to be one of the great sires of the country. Many English horses of small reputation, such as Esher, or horses that were never raced in England, like Eothen, have done well when mated with American blood.

For the most part the betting system adopted in the United States is the same as in England. In New York State what are described as "personal wagers," *i.e.*, bets between individuals on racecourses, are legal so long as no odds are displayed. Through the western states and in Canada odds are displayed on small blackboards, which are part of the appurtenances of stands, each occupied by a bookmaker and his clerks. The *pari-mutuel* system was used, but is now practically abolished, being specifically named as illegal in the State of New York. The selling of pools at auction, which was once the medium of most of the big betting in America, is also discontinued; and this too is illegal in New York. There is not a weekly settling day, as in England, but accounts are usually settled within twenty-four hours, unless by special arrangement.

Trotting.

In the United States interest in trotting races rivals that felt in the contests of thoroughbred horses. In the year 1834 a horse called Andrew Jackson trotted a mile in 2 m. $42\frac{1}{2}$ s., that being the fastest time which had then ever been accomplished. This was regarded as something very remarkable, and when eleven days later, on 27th October, the horse improved the time by 4 seconds, some followers of the sport appear to have supposed that finality was reached. It was not until 1858 that any considerable reduction was made in the record, in that year Ethan Allen having trotted a mile in 2 m. 28 s. In August 1874 Mambrino Gift was credited with 2 m. 20 s. For a time Goldsmith Maid held prominence with figures which she reduced in 1874 from 2 m. 16 s. to 2 m. 14 s., and in 1878 came Rarus, who went a mile in a quarter of a second less, the small fraction being esteemed a great thing. Other notable performances reducing the record were St Julian in 1879, 2 m. $11\frac{3}{4}$ s.; Maud S., 1881, 2 m. $10\frac{1}{4}$ s.; Jay-Eye-See, in 1885, 2 m. $8\frac{3}{4}$ s.; Sunol in 1891, 2 m. $8\frac{1}{4}$ s.; Nancy Hanks in 1892, 2 m. 4 s.; and Alix in 1894, 2 m. $3\frac{3}{4}$ s. The record at the beginning of 1902 is the 2 m. $2\frac{1}{4}$ s. made by Cresceus in 1901. Improved times have doubtless been the result of improved methods, as well as of care in the breeding of the trotter. Some very severe training rules used to be sedulously observed; about 1870, for instance, a horse never had water the night before a race, and the system generally appears to have overtaxed the animals' strength. A prominent consideration in trotting races is the adjustment of toe-weights, which are fastened on to the horses' feet to equalize their action, and it is found that horses improve their time to the extent of several seconds when properly shod. The American trotter is declared to be practically a thoroughbred. Pacing races are also frequent in the United States. In trotting the action may be described as diagonal; the pacer moves both legs on the same side at the same time, and both feet stride as one. A similar "gait," to employ the American term, was called in England some centuries ago an "amble." The pacer moves more easily and with apparently less exertion than the trotter, and the mile record (made by Anaconda in 1901) stands at 2 m. $1\frac{3}{4}$ s. Trotting and pacing races are sometimes contested in the saddle, more frequently in wheeled vehicles of the lightest possible description specially constructed for the purpose.

France.—Racing in France as conducted on modern lines may be said to date from the year 1833, when the French Stud Book was originated, and a body formed, somewhat after the model of the English Jockey Club, under the title of the Société d'Encouragement pour l'Amélioration des Races de Chevaux en France. Races took place in the Champs de Mars, and an unsuccessful attempt was made in 1834 to arrange for a course, or "hippodrome" as it is termed in France, at Maisons Laffite. Chantilly was, however, fixed upon as the principal racing centre; on the 22nd April 1836 the first meeting was held there, with five races on the card, the principal being the Prix d'Orléans, a stake of 3500 francs, named after the duc d'Orléans, one of the chief promoters of the fixture. Next day the first race for the Prix du Jockey Club was run, and won by Frank, the property of Lord Henry Seymour, who was then taking a very active part in French sport. The Prix du Jockey Club was then worth 5000 francs; the value has since increased to 200,000 francs. This race occupies in France the place of the English Derby. The Prix de Diane, which corresponds to the English Oaks, was first run in 1843. Chantilly still continues an important centre of the French Turf, and a great many horses are trained in the district. Attempts had been made to popularize racing at Longchamps prior to the year 1856, when the Société d'Encouragement obtained a lease, erected stands, laid out the course, and held their first meeting on the 27th August 1857. Next season two meetings were held, one of four days in the spring and another of three in the autumn; at the present time the sport is vigorously carried on from March to the end of October, except during a summer recess. In 1857 meetings under the auspices of the Société d'Encouragement began to take place at Amiens, Caen, Nantes, Versailles, Moulins, and other towns; and there were stakes for two-year-olds in the spring, though of late years the appearance of the young horses has been postponed to the 1st of August. Progress was rapid, and in 1863 two important events were contested for the first time, the Prix du Prince Impérial, which was designed to balance the English St Leger, but for obvious reasons faded out of the programme, and the Grand Prix de Paris, an international race for three-year-olds, run at Longchamps over a distance of 1 mile 7 furlongs, and now the most valuable stake in Europe. In 1901 the prize was £10,812. The first Grand Prix fell to an English horse, Mr Savile's The Ranger; two years later it was won by Gladiateur, winner of the English Derby and the property of the comte de Lagrange who raced equally in France and in England; the duke of Beaufort's Ceylon was successful in 1866, and the marquis of Hastings' Earl in 1868. Mr Savile's Cremorne followed up his Derby victory by a victory at Longchamps in 1872, as did Mr Baltazzi's Kisber four years later. English horses were also victorious in 1874 (Mr W. R. Marshall's Trent), in 1878 (Prince Soltykoff's Thurio), in 1880 (Mr C. Brewer's Robert the Devil), in

1881 (Mr Keene's Foxhall, who, however, should rather rank as an American horse), in 1882 (Mr Rymill's Bruce), in 1885 (Mr Cloete's Paradox), and in 1886 (Mr Vyner's Minting). During the first 23 years of the Grand Prix (owing to the war, the race did not take place in 1871) the stake fell to English horses—if Kisber and Foxhall be included—on twelve occasions, and generally to English jockeys. In recent years, however, French owners have held their own. In not a few respects racing is managed more judiciously than in England. The courses, for one thing, are better tended and maintained. At Epsom and Ascot, for instance, the trampling of the multitude beats down and destroys the herbage, making the ground cruelly hard for the horses to gallop over; in France the crowd is not allowed to wander about the course, and in the hottest summer weather the circuit of Longchamps is never hard and always refreshingly green. The five- and six-furlong races for others than two-year-olds, which are so common at English meetings, are comparatively rare in France, and the value of the prizes in an average day's racing is considerably higher across the Channel than in England. A very large percentage of trainers and jockeys are English, and the former are, as a rule, quite as expert as at Newmarket and elsewhere, though the average seems somewhat lower in France than in England. Transatlantic methods have been introduced by American jockeys since 1899. From the middle of February until the middle of December a race meeting within easy reach of Paris takes place almost every day, except during August, when the sport is carried on in the provinces, notably at Deauville. Near Paris, the chief centre after Longchamps is Maisons Laffite. At Longchamps, early in October, a race called the Prix du Conseil Municipal, worth £4000, for three-year-olds and upwards, over a mile and a half, was organized in 1893, and has usually attracted English horses, Mr Wallace Johnstone's Best Man having been successful in 1894, and Mr Sullivan's Winkfield's Pride the following year. Except when the Whip is challenged for and the challenge decided over the Beacon Course at Newmarket, no race is run in England over a longer distance than two miles and a half; but in France the Prix Gladiateur, of £1200 and a work of art value £100, 3 miles 7 furlongs, creates considerable interest at Longchamps in the autumn. The *pari-mutuel*, by which most of the betting is carried on in France, though bookmakers pursue their business there as in England, except that they are relegated to the backs of the stands, is described under the head of BETTING.

Steeple-chasing in France.

The first recognized steeplechase in France took place on 1st April 1884, at Croix de Berny, and was won by the comte de Vaublanc's May-fly, all the horses at that time being ridden by gentlemen. Sport does not seem to have been carried on with much spirit, for it is said that the death of an animal called Barcha, in 1839, nearly led to the abandonment of the meeting; and it was not till 1863, when the Société des Steeplechases de France was founded, that the business was resolutely taken in hand. Gravelle and Vincennes were the principal centres until 1873, when the Société obtained possession of the ground at Auteuil, where the excellent course now in use was laid out. In 1874 twelve days' racing took place here, the card each day including three steeplechases and a hurdle race, the "hurdles," however, being small fences, as they are at present. The Grand Steeplechase d'Auteuil was then for a stake of 30,000 francs, at the time the most valuable offered in any country; but, as in racing on the flat, the stakes have enormously increased in value, and in 1901 the Paris Grand Steeplechase, as the chief event is now called, credited the winner with £6020, the hurdle race being worth rather more than half as much. In England there is scarcely any steeplechasing between March and November, except at hunt meetings, but in Paris cross-country sport is pursued almost all through the year, the chief races at Auteuil taking place in June, about the time of the Grand Prix, which is always run between the English Epsom and Ascot meetings. The Auteuil course is laid out in the shape of the figure 8, with varied fences, several of which really test a horse's jumping capacity; and variety is further obtained by starting the fields in different places and traversing the course in different ways. St Ouen, a meeting within half an hour's drive of the Louvre, is entirely devoted to steeplechasing; and jumping is also carried on at Vincennes, Colombes, Enghien, and elsewhere near Paris, as also at Nice in January, at Dieppe and other places in August. As a rule, the stakes run for, especially at Auteuil, are very much larger than in England. There are none of the clubs and special enclosures such as at Sandown, Kempton, Hurst, Lingfield, Gatwick, &c., though portions of the stand are set apart for privileged persons. A fee of 20 francs is charged for admission to the chief French racecourses, with half as much for a lady's voucher, and the tickets give access everywhere but to the very few reserved portions. At Vincennes, St Cloud, and some other courses trotting races are also contested.

Other Countries.—Racing in Germany is mainly conducted under the authority of the Union Club of Berlin, the principal course being the Hoppegarten. Two-year-olds do not run until the 1st of June, except in Saxony, where they appear a month earlier. During the month of August there are several days' racing at Baden-Baden, steeplechases as well as flat races being run. Some of the more valuable stakes are usually contested by a proportion of horses from France and other countries, a few being occasionally sent from England. For years past blood-stock has been imported from England. In Austria the two centres of racing are Vienna and Budapest, each of which has its Jockey Club. Racing in Belgium derives no little support from the contiguity of the country to France. The headquarters of the Belgium Jockey Club are in the Bois de la Cambre at Boisfort, and meetings are held at Ostend, Antwerp, Spa, Bruges, and elsewhere. Steeplechases take place at Groenenval and on other Belgian courses, but are not of high class. Racing has not reached a great degree of excellence in Italy, though attempts have been made to improve competitors by the purchase of Melton, who won the Derby of 1885, and of other notable animals. Meetings take place at Florence, Padua, Bologna, and other places, but the stakes are usually small. (A. E. T. W.)

Horsens, a market town of Denmark, at the head of Horsens Fjord, on the east side of Jutland, 32 miles by rail south-west of Aarhus. In 1899 it was entered by 668 vessels of 71,704 tons, and cleared by 695 of 74,679 tons. The exports are chiefly bacon and butter; the imports, iron, yarn, coal, and timber. Population (1880), 12,654; (1901), 22,243.

Horsforth, a township in the Pudsey parliamentary division of Yorkshire, England, on the Aire, 5 miles north-west of Leeds by rail. The church of St Mary was built in 1883, and there are Baptist, Wesleyan, Friends', and other places of worship. Public buildings include a temperance hall and a mechanics' institute. There are extensive woollen manufactures, and in the neighbourhood quarries. Area of urban district, 2801 acres. Population (1881), 6346; (1901), 7785.

Horsham, a market town and railway station in the Horsham parliamentary division (since 1885) of Sussex, England, 18 miles north-north-west of Brighton. The town-hall and grammar-school have been rebuilt, and a cottage hospital established. Population of urban district (1881), 6874; (1901), 9446.

Horsley, John Callcott (1817——), English painter, son of William Horsley, the musician, and grand-nephew of Sir Augustus Callcott, was born in London, 29th January 1817. He studied painting in the Academy

which we have been describing, may be gathered from the circumstances that it costs from £300,000 to £400,000, that it usually contains from 500 to 700 beds, and that the staff numbers from 350 to 500 persons. The medical superintendent lives in a separate house of his own. The nurses are provided with a home, consisting of several blocks of buildings under the control of the matron: the charge-nurses usually occupy the main block, where the dining and general sitting-rooms are placed; the day assistant-nurses another block; and lastly, by a most excellent arrangement, the night-nurses, 80 to 120 in number, have one whole block entirely given up to their use. The female servants have a second home under the control of the housekeeper, and the male servants occupy a third home under the supervision of the steward. The two main ideas aimed at are to disconnect the houses occupied by the staff from the infected area, and to place the members of each division of the staff together, but in separate buildings, under their respective heads. These objects are highly to be commended, as they have important bearings upon the well-being and discipline of the whole establishment, and constitute a lesson for all who have to do with buildings where a great number of people are constantly employed.

The circular ward is growing in favour. At the Great Northern Central Hospital, Holloway, where the site in a crowded district was most awkward, it fulfils a useful purpose, for by making some of the wards rectangular and others circular, the hospital was so planned as to give the same amount of cubic, wall, and superficial space per bed throughout the institution, irrespective of the shape of the wards. The first circular wards actually occupied by hospital patients were those of the Miller Hospital, Greenwich, shortly followed by the Municipal Hospital, Antwerp, the Victoria Hospital, Burnley, the Infirmary of the Hampstead Workhouse, two small military hospitals at Milton near Gravesend and Seaford near Liverpool, the Royal Infirmary at Liverpool, the Northern Hospital, Liverpool, and elsewhere. An important feature of this form of ward is its attachment to the main building, which should be by covered bridges with open spaces between the roof of one bridge and the floor of the one above. The centre space has been utilized as a nurses' room, as a ventilating shaft, or as a shaft for a spiral staircase leading to a flat roof used as a sun-room, but all these schemes are objectionable and often unsightly. A circular ward to be typical must be a ward only. To contain 12 beds it should have a diameter of about 42 feet, and in the centre there should be ventilators and flues with fireplaces, while for 20 beds the following should be the approximate dimensions:—Height, average, 13 feet (ceiling sloping up from periphery to centre); diameter, 57½ feet; wall space, 8·50 feet per bed; area, 128 feet per bed; cubic space, 1665 feet per bed; window area, 26·8 feet per bed. An octagonal ward has been tried at the Johns Hopkins Hospital, Baltimore, but has not proved satisfactory; it does not lend itself conveniently to the arrangement of the beds, and the dust catches the angles where the sides of the octagon join, so that the walls become speedily discoloured and unsightly.

Electricity is now a favourite agent for lighting hospital wards, but for many reasons it is desirable that it should always be supplemented by gas. In 1889, surgeons were on more than one occasion left in total darkness when performing an operation by electricity in a London hospital. As a system of illumination for hospitals it has great advantages, for it is cleanly, convenient, portable, and enables the surgeon to bring the light exactly where he wants it without moving his patient. Teak and maple are found to be the best wood for the floors. Wood has been superseded by terrazzo, but this in practice proves to be unsatisfactory, owing to its liability to crack when used for hospital purposes. These cracks may be seen in the terrazzo floors introduced into several of the recently erected modern hospitals. Very marked improvement has taken place in regard to hospital furniture. The bedsteads are ornamental, simple, and specially constructed for hospital purposes (Guy's Hospital pattern). Ward tables and lockers are glass-topped; and invalid chairs and ambulance litters have been generally adopted for ward use. The number of operations in a modern hospital in existing circumstances is at least four times as great as it was a few years ago. In consequence a demand has grown up for a large number of small operating theatres of new and aseptic types, which cost prodigious sums.

Persistent efforts have been made in favour of the plenum system of ventilation (see *Ency. Brit.*, 9th ed., vol. xxiv. p. 160) for British hospitals. Of the necessity for ventilation there can be no doubt, and upon the fundamental principles which determine the quantity of air to be supplied, the temperature it is to be supplied at, and the rate at which the air is to be changed, authorities are practically agreed. In the United States, and in most Continental countries, more especially in France, it is deemed necessary to adopt mechanical means for renewing the air of wards. In Great Britain, notwithstanding some instances of a contrary practice, or probably because of such instances, it is held that the most efficient ventilation is to be obtained by the use of the simplest means. Having regard to the temperate character of the English climate, artificial ventilation, whatever be the plan adopted, is not desirable, if it even be permissible, especially when entire reliance is placed upon such a system for the whole ventilation of the sick wards of any British hospital which is constantly filled with surgical and other cases requiring abundance of fresh air. The question is exhaustively treated in Burdett, *Hospitals and Asylums of the World*, vol. iv. pp. 43 *et seq.* The plenum system may be a necessity in operating theatres and in out-patient departments, but its application to English wards is neither necessary, nor desirable, nor economical.

The cottage hospital movement has spread to all parts of the United Kingdom, and is now making its way in the United States, and especially in New England. There are upwards of three hundred cottage hospitals in the United Kingdom at the present time. Everywhere they are becoming most efficient and complete hygienically; indeed, many are now as perfect as a single pavilion of a great modern hospital. The amount of good they have conferred upon residents in rural districts is very great. They benefit the community by affording all classes the best kind of skilled medical attendance, and so they attract the wealthy to out-of-the-way places by ensuring adequate treatment by skilled practitioners for operation, accident, and other cases. Thanks to them, residents in the country can nowadays obtain most of the medical advantages of residents in cities.

The attempt to introduce the pay hospital into England has proved successful, and since the Home Hospitals Association opened the first of these establishments at Fitzroy House, Fitzroy Square, in 1880, it has proved a boon to hundreds of surgeons and their middle-class patients. The St Thomas's Home, a wing of St Thomas's Hospital, has been given up to the accommodation of paying patients for several years, though the authorities, for some reason not very apparent, are desirous of discontinuing the system. The pay ward, though a common feature of Continental and American hospitals, has been adopted in a tentative way at Guy's Hospital and the Great Northern Central Hospital, where there is a separate wing set apart for paying patients. It is most desirable that pay wards should be erected in connexion with every general hospital of importance throughout the United Kingdom, but the medical staff should be paid for attendance on such cases. In that way hospital abuse would be abolished, and every patient would enjoy the right, which is undoubtedly his, to be attended by his own doctor, and to pay according to his means for the treatment he receives during his residence in hospital.

A revolution has taken place in nursing, which, once a calling, is now denominated a "profession." The duties of nurses are confined to attendance on the sick. They are housed in separate pavilions, have many fewer hours' work in the wards than formerly, and are allowed a reasonable time for recreation, longer holidays, and much better food. Their training extends over three years at least, and during their course they attend lectures and practical classes on bandaging, dressing, cooking, the elements of hygiene, practical surgery, and the elements of anatomy and physiology. The menial work of a hospital, such as scrubbing floors and housework generally, is entrusted to a staff of servants or ward maids employed exclusively for such purposes. Practical instruction is also made available for nurses in midwifery, fever nursing, the attendance on patients in private families, and mental nursing. The remuneration has increased quite 30 per cent., and private nurses sometimes earn as much as from £100 to £130 a year. The number, too, in hospitals has been enormously increased, the proportion in a well-regulated hospital now being one nurse to every four patients. In some hospitals there is one nurse to every two occupied beds, but this number is disproportionate if due regard be had to economical considerations.

Hot Springs, capital of Garland county, Arkansas, U.S.A., on the Hot Springs Railway, at an altitude of 575 feet. The city was originally situated in a narrow water gap in one of the ridges of the Ozark Mountains, whence it has spread into the valleys north and south. Its plan is very irregular. The springs from which the city derives its name, and which have made it famous, are very numerous on the ridge on the east side of the gap, whence the water is piped into the town. They are of value in rheumatic, syphilitic, and cutaneous diseases, and thousands of sufferers visit the place yearly for relief. For their accommodation many large hotels have been constructed, and the United States has an army and navy hospital here. Population (1880), 3554; (1890), 8086; (1900), 9973, of whom 561 were foreign-born and 3102 were negroes.

Hottentots.—In recent years these aborigines have been carefully studied by Fritsch, Shrubsall, Hamy, and several other leading anthropologists, whose researches tend to show that they are not "totally distinct from all other African races," as was formerly generally supposed (*Ency. Brit.* vol. xii. p. 309). They are, on the contrary, now held to be, not so much a distinct or independent variety of mankind as the result of a very old cross between two other varieties—the Bantu Negro and the pigmy Negrito-Bushman. (See BUSHMEN.) Hamy calls them simply "Bushman-Bantu half-breeds," the Bushman element being of the two the more pronounced, as seen in the leathery colour, compared to that of the "sere and yellow leaf"; in the remarkably prominent cheek-bones and pointed chin, giving the face a peculiarly triangular shape; and lastly, in such highly specialized characters as the *tablier* and the *steatopygia* of the women, constant in the Bushman from infancy, but developed only in the adult Hottentot woman, and that not universally. The cranial capacity is also nearly the same (1331 c.c. in the former, 1365 c.c. in the latter), and on these anatomical grounds Shrubsall concludes that the two are essentially one race, allowing for the undeniable strain of Bantu blood in the Hottentot.

This view is further strengthened by the vast range in prehistoric times of the Hottentot variety, which, since the time of Lichtenstein (1800–04), was known to have comprised the whole of Africa south of the Zambezi, but has recently been extended as far north as the equatorial lake region. This important fact in African ethnology is due to the explorations of Oskar Neumann in the district between Lake Victoria and Mount Kilimanjaro, where this traveller came upon the *Wasandawi* people, a sort of Hottentot enclave in the midst of the Negroid-Bantu populations, speaking a non-Bantu language full of clicks like that of the Bushman-Hottentots, and presenting cranial characters—projecting upper jaw, orthodolicho head and low capacity—exactly like those of the Namas and other full-blood Hottentots.[1]

But very few of these full-blood Hottentots now survive even in their present restricted domain south of the Zambezi. Of the half-dozen groups that still call themselves *Khoi-Khoin* ("Men of Men") the Namas alone of Great and Little Namaqualand preserve the racial type and speech in tolerable purity. All the others are more or less degraded Hottentot-Dutch or Hottentot-Bantu half-breeds, mainly of debased Dutch speech, although the Koranas of the Upper Orange, Vaal, and Modder rivers still here and there speak a moribund Hottentot jargon flooded with Dutch and English words and expressions. This Korana jargon, like the "English" of the Liberian negroes, is so corrupt that it has become quite useless for any literary purposes, and is now no longer employed by the missionaries in their intercourse with the natives.

But Hottentot speech still survives in a tolerably pure state, not only amongst the Namas, but also in Damaraland, where it has long been spoken by the so-called "Hill Damaras" of the north-eastern uplands. These *Hau-Khoin* ("True Men"), or *Hau-Damop* ("True Damas"), as they call themselves, are not "true" Hottentots at all, but a Bantu people with a slight admixture of Hottentot blood, who were at some unknown period assimilated in speech to their Dama[2] conquerors. The fundamental connexion of this language with that of the Bushmen, already suggested by Bleek, is supported by further evidence advanced by the late G. Bertin. But its relation to ancient Egyptian, a view at one time generally accepted on the authority of Dr R. Lepsius, rests on no solid grounds, and indeed is now shown to be untenable. In Egyptian, a Hamitic tongue with remote Semitic affinities, there are no clicks, which form an essential element of Hottentot phonetics, and the two languages differ also fundamentally in their lexical and structural characters.

Subjoined is a tabulated statement of the surviving Hottentot groups, all of whom, except perhaps the Namas, are disappearing by a slow process of extinction or absorption amongst the surrounding Boer and native populations. No Hottentot-English half-breeds are yet spoken of in any part of South Africa:—

Tribal Groups.	Domain.	Population (1890–99).
Northern Namas	Great Namaqualand	12,000
Oerlams	" "	5,000
Southern Namas	Little Namaqualand	3,000
Hill Damaras	N.E. Damaraland	26,000
Koranas	Upper Orange, Vaal, and Modder rivers	15,000
Griquas	Griqualand East	4,000
Gonaquas	Kaffre Borderlands	35,000 ?
Dispersed	Cape Colony	80,000 ?
Total full-blood and half-castes		180,000

Some of these terms still need explanation. The *Oerlams* of Great Namaqualand came originally from Little Namaqualand in Cape Colony, whence perhaps their name, which is said to be a corruption of the Dutch *Oberlanders*. All now speak Dutch, have given up the tribal system, and form semi-civilized Christian communities, differing little from those of the other settled populations, from whom they will scarcely be distinguishable in a few generations.

The *Griquas*, called by the Dutch *Baastards*, are a cross between the early Boer settlers and their female Hottentot slaves. After forming a semi-independent state on the Roggeodde uplands about 1800, most of them were driven (1815) by the whites across the Orange to the district from them named Griqualand, now Griqualand West. Here they again set up for themselves till the discovery of diamonds, when the territorial rights of their chief, Waterboer, were surrendered to the Colonial Government for a sum of money and compensation elsewhere (1871). Thereupon the bulk of these western Griquas joined their eastern kindred in the district which was formerly known as Noman'sland, but took the name of Adam Kok's Land in 1862, when it was assigned by the British Government to this Griqua chief and his people, refugees from their Boer oppressors in the Orange Free State. Later Adam Kok's Land was incorporated in Cape Colony as a separate administrative division, and re-named Griqualand East to distinguish it from the diamantiferous Griqualand West, which had already been annexed to Cape Colony in 1880. The great majority of the Griquas are now settled in the eastern division, where they live in harmony with the surrounding Basuto and

[1] Dr R. Virchow, *Verhandl. Berl. Ges. f. Anthrop.* 1895, p. 59, and Dr Mies, *Centralbl. f. Anthrop.* 1896, p. 50. Of a Hottentot skull from a cave on the Orange-Transvaal frontier, Dr Mies states that "its form is orthodolichocephalic, as with the Wasandawi" (*ib.*).

[2] The dual fem. form *Damara* ("Two Dama Women"), whence the geographical term "Damaraland" (the *Hereroland* of the Germans), was due to a misapprehension, for which see A. H. Keane's *Africa*, vol. ii. p. 176.

white populations. Many, however, have sold their lands, and thus sunk to the position of proletariates.

The *Gonaquas*, *i.e.*, "Borderers," are descendants of a very old cross between the Hottentots and the Kaffres, which sprang up on the "ethnical divide" between the two races apparently before the advent of the whites. They have always been treated with contempt, and regarded as outcasts by the Ama-Xosa Bantus, and would have been exterminated during the Kaffre wars but for the intervention of the British. At present they live in settled communities under civil magistrates without any tribal organization, and in some districts could scarcely be distinguished from the other natives but for their broken Hottentot-Dutch-English speech.

All the other natives to whom the term Hottentot can be in any way applied are now dispersed throughout Cape Colony, where they find employment about the farmsteads and in the households in various menial services. They generally speak a Dutch jargon, which in some places is being replaced by an equally debased "pidgin English."

Houghton, Richard Monckton Milnes, 1st BARON (1809–1885), English poet and man of letters, son of Robert Pemberton Milnes, of Fryston Hall, Yorkshire, by the Hon. Henrietta Monckton, daughter of the fourth Lord Galway, was born in London, 19th June 1809. He was educated privately, and entered Trinity College, Cambridge, in 1827. There he was at once drawn into a literary set, and became a member of the famous "Apostles" Club, which then included Tennyson, Hallam, Trench, Blakesley, and other men of uncommon promise. He took his M.A. degree in 1831, and travelled abroad, spending some time at Bonn University. Thence he went to Italy and Greece, and published in 1834 a volume of *Memorials of a Tour in some Parts of Greece*, describing his experiences. He returned to London in 1837, and was in that year elected to Parliament as member for Pontefract. His parliamentary career was marked by much strenuous activity. He interested himself particularly in the question of copyright and the conditions of reformatory schools. He left Peel's party over the Corn Law controversy, and was afterwards identified with Palmerston's politics. Church matters had always a claim upon him: he wrote a striking tract in 1841, which was praised by Newman; and took part in the discussion about "Essays and Reviews." His literary career was industrious and cultured, without being exceptionally distinguished. He published two volumes of verse in 1838, *Memorials of Residence upon the Continent* and *Poems of Many Years*, *Poetry for the People* in 1840, and *Palm Leaves* in 1844. He also wrote a *Life and Letters of Keats* in 1848, and contributed largely to the reviews. His poetry is meditative and delicate; some of his ballads were among the most popular of their day, and all his work was marked by refinement. But his chief distinctions were his keen sense of literary merit in others, and the judgment and magnanimity with which he fostered it. He was surrounded by the most brilliant men of his time, many of whom he had been the first to acclaim. He secured a pension for Tennyson, pressed the claims of Emerson in Great Britain, and was one of the earliest champions of Mr Swinburne. He was, in the old sense of the word, a patron of letters, and one who never abused the privileges of his position. Milnes married in 1851 the Hon. Arabella Crewe (who died in 1874), and was made a peer in 1863. He died at Vichy on the 11th of August 1885, and was buried at Fryston. (A. WA.)

Houghton-le-Spring, a township in the Houghton-le-Spring parliamentary division of county Durham, England, 6 miles north-east of Durham city. St Michael's Church is ancient, of Early English and Decorated styles, and has been recently restored. St Andrew's, built in 1876, was enlarged in 1883. There are also a Roman Catholic and various Nonconformist chapels. Bernard Gilpin, "the Apostle of the North," was rector of this parish from 1556 to 1583, and the founder of the grammar-school. There are almshouses, church institutes, and a town-hall and market-place. The Durham to Sunderland main road here passes through a romantic limestone rock cutting 80 feet deep. The district affords frequent evidence of ice activity in the Glacial Period. The town is the radiating centre of a large projected scheme of electrical tramways. The population is mainly dependent on the neighbouring collieries, but limestone quarrying is carried on to some extent. Area of township (an urban district), 1551 acres. Population (1881), 6041; (1901), 7858.

Hounslow, a town of England, 12 miles west by south of St Paul's, London, in the Brentford parliamentary division of Middlesex; stations on the London and South-Western and the Metropolitan District Railways. The town has two parish churches, Holy Trinity (1835) and St Paul's (1874), and a district church, St Stephen's (1876). A Roman Catholic church was built in 1886; there are Congregational, Baptist, Methodist, and other places of worship. The town hall was built in 1857, and the Urban District Council offices in 1889. The Middlesex County Council has here a polytechnic institute (1892). Hounslow Hospital (1881) was enlarged in 1893. Hounslow is partly in Isleworth parish and partly in Heston. Population (1881), 10,459; (1901), 11,377.

Houston, capital of Harris county, Texas, U.S.A., on Buffalo Bayou, at the head of navigation, at an altitude of 53 feet. The site of the city, which is the second in size in the state, is level, and the plan fairly regular. With its navigable bayou, giving water communication with the Gulf of Mexico, and ten railways communicating with all parts of the state, it has a very large trade, especially in cotton, cotton-seed oil, and lumber. It is a commercial rather than a manufacturing city. In 1890 its manufactures had a capital of $3,509,434, employed 3009 hands, and produced goods valued at $6,832,943. The assessed valuation of real and personal property in 1900 (on a basis of assessment of about two-thirds of the full value) was $27,480,898; the tax-rate was $29·47 per $1000, and the net debt was $2,785,721. Population (1880), 16,513; (1890), 27,557; (1900), 44,633, of whom 4415 were foreign-born and 14,608 were negroes.

Hovas. See MADAGASCAR.

Hove. See BRIGHTON.

How, William Walsham (1823–1897), English bishop, son of a Shrewsbury solicitor, was born 13th December 1823, and was educated at Shrewsbury School and Wadham College, Oxford. He was ordained in 1846, and for upwards of thirty years was actively engaged in parish work. He refused preferment on several occasions, but his energy and success made him well known, and in 1879 he became a suffragan bishop in London, under the title of bishop of Bedford, his province being the East End. He became the inspiring influence of a revival of Church work in that district. He founded the East London Church Fund, and enlisted a large band of enthusiastic helpers, his popularity among all classes being immense. He was particularly fond of children, and was commonly called "the children's bishop." In 1888 he was

made bishop of Wakefield, and in the north of England he continued to do valuable work. His sermons were straightforward, earnest, and attractive; and besides publishing several volumes of these, he was a vigorous and elegant writer of hymns and other verses. In the movement for infusing new spiritual life into the Church services, especially among the poor, Bishop Walsham How was a great force, his tact and geniality being of particular value. He died 10th August 1897. He had married Miss Frances A. Douglas in 1849, and his wife was of much assistance to him in his work, but she died in 1887.

Howard, Oliver Otis (1830- ——), American soldier, was born in Leeds, Me., on 8th November 1830. He graduated at Bowdoin College in 1850, and at the U.S. Military Academy in 1854. Resigning from the regular army in 1861 to take command of the 3rd Maine Regiment, he became, in September 1861, a brigadier-general of volunteers, and major-general in November 1862. He was twice wounded at Fair Oaks, 1st June 1862, losing his right arm; fought in 1863 at Chancellorsville and Gettysburg, and, transferred to the west, served at Chattanooga and during Sherman's operations (1864–65). He became a brigadier in the United States army on the 21st December 1864, was major-general in 1886, and retired in 1894. Howard University, established at Washington for the education of the negro race, was named in his honour.

Howe, Julia Ward (1819- ——), American poet and reformer, daughter of Samuel Ward, was born in New York, 27th May 1819. In 1843 she married Dr Samuel Gridley Howe (1801–1876), a pioneer in the education of the blind and of blind deaf-mutes, whose success in the instruction of Laura Bridgman attracted the attention of Charles Dickens and of many philanthropists. Mrs Howe wrote several volumes of poems, her best-known piece being the "Battle-Hymn of the Republic," which, set to the music of "John Brown's body lies a-mouldering in the grave," had great vogue in the Northern States of America during the war of 1861–65. She has engaged actively in movements on behalf of the anti-slavery cause and of woman-suffrage. Her poems were published under the titles of *Passion Flowers* (1854), *Words for the Hour* (1856), and *Later Lyrics* (1866); and she has also written *Sex in Education* (1874), *Modern Society* (1880), and *Margaret Fuller* (1883).

Howells, William Dean (1837- ——), American novelist, was born at Martinsville, Ohio, 1st March 1837. His father, William Cooper Howells, a printer-journalist, moved in 1840 to Hamilton, Ohio, and here the boy's early life was spent successively as type-setter, reporter, and editor in the offices of various newspapers. In the midst of routine work he contrived to familiarize himself with a wide range of authors in several modern tongues, and to drill himself thoroughly in the use of good English. In 1861, as assistant editor of the leading republican newspaper in Ohio, he wrote—in connexion with the Presidential contest—the campaign life of Lincoln; and in the same year he was appointed consul at Venice, where he remained till 1865. On his return to America he joined the staff of the *Atlantic Monthly*, and from 1871 to 1881 he was its editor-in-chief. Since 1885 he has lived in New York. For a time he conducted for *Harper's Magazine* the department called "The Editor's Study," and in December 1900 he revived for the same periodical the department of "The Easy Chair," which had lapsed with the death of George William Curtis. Of Mr Howells's many novels, the following may be mentioned as specially noteworthy: *Their Wedding Journey*, 1871; *The Lady of the Aroostook*, 1879; *A Modern Instance*, 1882; *The Rise of Silas Lapham*, 1885; *The Minister's Charge*, 1886; *A Hazard of New Fortunes*, 1889; *The Quality of Mercy*, 1892; *The Landlord at Lion's Head*, 1897. Mr Howells is by general consent the foremost representative of the realistic school of indigenous American fiction. From the outset his aim has been to portray life with entire fidelity in all its commonplaceness, and yet to charm the reader into a liking for this commonplaceness and into reverence for what it conceals. Though in his earliest novels his method was not consistently realistic—he is at times almost as personal and as whimsical as Thackeray—yet his vivid impressionism and his choice of subjects, as well as an occasional explicit protest that "dulness is dear to

William Dean Howells
(From a photograph by C. F. Conby, Boston.)

him," already revealed unmistakably his realistic bias In *A Modern Instance* (1882) he gained complete command of his method, and began a series of studies of American life that are remarkable for their loyalty to fact, their truth of tone, and their power to reveal, despite their strictly objective method, both the inner springs of American character and the sociological forces that are shaping American civilization. Mr Howells's method, as finally developed in his more serious fiction, is noteworthy for its restraint and its conscientious impersonality. He refuses to over-sophisticate or to over-intellectualize his characters, and he is very sparing in his use of psychological analysis. He insists on seeing and portraying American life as it exists in and for itself, under its own skies and with its own atmosphere; he does not scrutinize it with foreign comparisons in mind, and thus try to find and to throw into relief unsuspected configurations of surface. He keeps his dialogue toned down to almost the pitch of everyday conversation, although he has shown in his comedy sketches how easy a master he is of adroit and witty talk. His style is in general transparent and rigorously plain, and his humour impersonal and dramatic. That he is at times the victim of a superstition for the commonplace even his warmest admirers can hardly deny. Life in America has, after all, greater charm of manner and greater intellectual and social refinement than he seems willing to admit. He has

the air of obstinately choosing sordid material, as if he were ambitious to outdo the gods themselves in creating beauty. Yet, on the other hand, he has been again and again justified of his ambition, and has compelled some apparently quite prosaic bit of life to exhale a quaint poetic fragrance or to reveal a poignant tragic quality. Taken altogether, his novels doubtless offer a more penetrating and comprehensive interpretation of American life than can be found in the works of any other writer of fiction.

Howitt, Mary (1799–1888), English writer, daughter of Samuel Betham, was born at Coleford, Gloucestershire, 12th March 1799. She began to write verse when quite young, and in 1821 married William Howitt (see *Ency. Brit.* vol. xii. p. 324). She and her husband collaborated throughout a long literary career, Mrs Howitt's own contributions being of a varied and voluminous description, consisting of poems, songs, stories, &c. A month after her husband's death in 1877, Mrs Howitt was given a Civil List pension of £100 a year. Mary Howitt died 30th January 1888. Brought up as a Quaker, she left the Society of Friends in 1847; and after passing through a stage of spiritualism, she joined the Church of Rome in 1882.

Howrah, a city and district of British India, in the Burdwan division of Bengal. The city is situated opposite Calcutta, with which it is connected by a floating bridge. The municipal area is about 11 square miles; the population in 1881 was 105,628, in 1891 it was 116,606, and in 1901 it was 157,847, showing an increase of 35 per cent. Howrah is the terminus of the East Indian Railway, and of the Bengal-Nagpur and East Coast lines. A project has been under consideration for carrying all these railways into Calcutta by a permanent bridge across the river. Howrah is also the centre of two steam tramways, which run for 29 and 19 miles into the country. Further, it is the headquarters of the jute-manufacturing industry, with many steam presses and steam mills, and there are four cotton mills (see Bengal). There is a paper mill, employing 1000 hands, with an annual out-turn valued at Rs.14,00,000; six flour mills, employing 300 hands, with a yearly out-turn valued at Rs.30,00,000; several foundries and iron-works, one of which alone employs more than 3000 hands, with an annual out-turn valued at Rs.24,00,000; two oil mills; two large ropeworks; and factories of safety matches and umbrellas. Sibpur Engineering College lies on the outskirts of the town. There is a hospital, with a department for Europeans. The District of Howrah extends southwards down the right bank of the Hooghly to the confluence of the river Damodar. For revenue purposes it is included within the district of Hooghly. Its area is 476 square miles; the population in 1881 was 635,381, in 1891 it was 721,211, giving an average density of 1515 persons per square mile. In 1901 the population was 852,008. The number of police was 667; the number of boys at school in 1896–97 was 31,777, being 55 per cent. of the male population of school-going age; the registered death-rate in 1897 was 29·32 per thousand. In addition to the two steam tramways and the East Indian Railway, the district is crossed by the high-level canal to Midnapur, which communicates with the Hooghly at Ulubaria. The manufacturing industries of Howrah extend beyond the town into the district. One or two systems of draining low-lying lands are maintained by the Government.

Höxter, a town of Prussia, province of Westphalia, on the Weser, 32 miles north of Cassel. The town-house dates from 1466 and 1613, and there are churches of the 11th and 14th centuries, as well as numerous houses of the 16th. The town possesses various industries—cement, paper, gutta-percha, &c.—and an architectural school. It grew out of a royal estate which dates from 823, and eventually became a free imperial town and a member of the Hanseatic League, with a mint and staple of its own. Population (1885), 6046; (1900), 7625. Close to Höxter is the abbey of Corvey, one of the most famous Benedictine monasteries in Germany, founded in 822 and secularized in 1803; the "castle" contains a valuable old library of some 55,000 volumes. Hoffmann von Fallersleben, who was librarian from 1860 to 1874, is buried behind the abbey church.

Huallaga. See Amazon.

Huancavelica, an interior department of Central Peru. It has an area of 10,814 square miles, and (1896) a population of 223,796, or 20 persons to the square mile. It contains the four provinces of Tayacaja, Huancavelica, Angaraes, and Castrovireyna. The capital, Huancavelica, has a population of 8000.

Huanuco, an interior department of Central Peru. It has an area of 14,023 square miles, and a population (1896) of 145,309, or 10 persons to the square mile. It is divided into the three provinces of Huamalies, Dos de Mayo, and Huanuco. Its capital, Huanuco, is 170 miles north-north-east of Lima.

Hubli, a town of British India, in the Dharwar district of Bombay, 15 miles south-east of Dharwar town. Population (1881), 36,677; (1891), 52,595; (1901), 58,149. It is a railway junction on the Southern Mahratta system, where the lines to Bangalore and Bezwara branch off south and west. It is an important centre of trade and of cotton and silk weaving, and has a cotton mill with 18,880 spindles, employing 725 hands, eleven factories for ginning and pressing cotton, and a printing-press, issuing a newspaper in vernacular and English.

Hübner, Joseph Alexander, Count (1811–1892), Austrian diplomatist, was born in Vienna on 26th November 1811. His real name was Hafenbredl, which he afterwards changed to Hübner. He began his public career in 1833 under Metternich, whose confidence he soon gained, and who sent him in 1837 as attaché to Paris. In 1841 he became secretary of embassy at Lisbon, and in 1844 Austrian consul-general at Leipzig. In 1848 he was sent to Milan to conduct the diplomatic correspondence of Archduke Rainer, viceroy of Lombardy. On the outbreak of the revolution he was seized as a hostage, and remained a prisoner for some months. Returning to Austria, he was entrusted with the compilation of the documents and proclamations relating to the abdication of the Emperor Ferdinand and the accession of Francis Joseph. His journal, an invaluable clue to the complicated intrigues of this period, was published in 1891 in French and German, under the title of *Une Année de ma Vie, 1848–1849*. In March 1849 he was sent on a special mission to Paris, and later in the same year was appointed Ambassador to France. To his influence was in large measure due the friendly attitude of Austria to the Allies in the Crimean War, at the close of which he represented Austria at the Congress of Paris in 1856. He allowed himself, however, to be taken by surprise by Napoleon's intervention on behalf of Italian unity, of which the first public intimation was given by the French Emperor's cold reception of Hübner on New Year's Day, 1859, with the famous words: "I regret that our relations with your Government are not so good as they have hitherto been." He did not return to Paris after the war, and after holding the ministry of police in the Goluchowski cabinet from August to October 1859,

lived in retirement till 1865, when he became ambassador at Rome. Quitting this post in 1867, he undertook extensive travels, his descriptions of which appeared as *Promenade autour du Monde, 1871* (1873; English translation by Lady Herbert, 1874), and *Through the British Empire* (1886). Written in a bright and entertaining style, and characterized by shrewd observation, they achieved considerable popularity in their time. A more serious effort was his *Sixte-Quint* (1870; translated into English by H. E. H. Jerningham under the title of *The Life and Times of Sixtus the Fifth*, 1872), an original contribution to the history of the period, based on unpublished documents at the Vatican, Simancas, and Venice. In 1879 he was made a life-member of the Austrian Upper House, where he sat as a Clerical and Conservative. He had received the rank of Baron (Freiherr) in 1854, and in 1888 was raised to the higher rank of Count (Graf). He died at Vienna on 30th July 1892. Though himself of middle-class origin, he was a profound admirer of the old aristocratic *régime*, and found his political ideals in his former chiefs, Metternich and Schwarzenberg. As the last survivor of the Metternich school, he became towards the close of his life more and more out of touch with the trend of modern politics, but remained a conspicuous figure in the Upper House and at the annual delegations. That he possessed the breadth of mind to appreciate the working of a system at total variance with his own school of thought was shown by his grasp of British colonial questions. It is interesting, in view of subsequent events, to note his emphatic belief in the loyalty of the British colonies—a belief not shared at that time by many statesmen with far greater experience of democratic institutions. With strange inconsistency, he refused to apply these conclusions to the internal politics of his own country. (H. SY.)

Huddersfield, a municipal, county (1888), and parliamentary borough and market town in the West Riding of Yorkshire, England, on the Colne, 190 miles by rail north-north-west of London. The municipal borough was extended in 1890, and is now distributed into 13 wards under a mayor, 15 aldermen, and 45 councillors. St Mark's Church was erected in 1887, and Longwood Grammar School (1731) reorganized in 1892. There are now 18 board schools (the college higher grade having been acquired by the school board in 1893), 22 national, and 2 Roman Catholic schools. The reservoirs of the waterworks will hold 1,159,000,000 gallons, and two other reservoirs, now in course of construction, about 460,000,000 gallons. These works have cost over a million sterling. A new theatre was built in 1881. In 1891, 6258 males and 4845 females were employed in the manufacture of woollen cloth, 1295 males and 2195 females in the manufacture of worsted stuff, and 1144 males and 1252 females in the manufacture of cotton goods. There are two daily newspapers. Area, 11,852 acres. Population (1881), 86,502; (1901), 95,008.

Hudson, a town of Middlesex county, Massachusetts, U.S.A., on the Boston and Maine and the Fitchburg Railways. It has an area of 13 square miles of hilly surface, containing a village of the same name, situated on the Assabet, at an altitude of 226 feet. Population (1880), 3739; (1890), 4670; (1900), 5454, of whom 1225 were foreign-born.

Hudson, capital of Columbia county, New York, U.S.A., on the east bank of the Hudson river. It has three railways—the Boston and Albany, the New York Central and Hudson River, and the Kinderhook and Hudson—as well as steamboat lines on the river connecting it with New York and Albany. It has manufactures of varied character. Population (1880), 8670; (1890), 9970; (1900), 9528, of whom 1155 were foreign-born and 424 were negroes.

Hué, capital of Annam, near the mouth of Hué river, on the coast of Cochin-China, French Indo-China. Formerly closed to Europeans, French enterprise is now active in its midst. The royal palace, once forbidden ground, is to-day open to foreigners, and the citadel is occupied by French troops. The palace of the French resident-general, opposite the citadel on the right bank of the Hué—the *Song-Huon-Giang*—is connected with the citadel by a stationary bridge 1150 feet in length. A glass factory has been established, and a frequent service of steam launches connects the town with the ports of Tuan-an and Tourane. The population (1901) includes twenty-three Europeans (exclusive of officials), 50,000 Annamese, and 300 Chinese. Important suburbs have gathered round the official town, the villages of Dông-Bo, Bo-vinh, Gia-Ho, and Kim-Long forming a sort of commercial belt about the governmental city. The apostolic vicariate of northern Cochin-China is established near Kim-Long. (J. M. A. DE L.)

Huehuetenango, a city of Guatemala, capital of a department of the same name. It is situated in a fertile plain, watered by the Chiapas, a tributary of the Rio Grijalva, 106 miles north-west of Guatemala. In the neighbourhood there are lead mines, and at a short distance from the city, on a terrace surrounded by ravines, are important remains of an ancient Indian capital. Population, 12,000.

Huelva, a maritime province of south-western Spain. The area is 4122 square miles, divided into six administrative districts and seventy-seven parishes. The means of communication have been very much improved. A broad-gauge railway, 68 miles in length, has been opened between Seville and Huelva, and another, 112 miles long, from Huelva to Zafra, and other lines are in course of construction. There are, besides, 135 miles of narrow-gauge lines, connecting Huelva with the mines of Rio Tinto, Tharsis, Buitron, and Zalamea, and minor branches from Tharsis to La Zarza, and Cuervo to Sotul mines. There are 98 miles of first-class state roads, and very many useful provincial second- and third-class roads. Apart from vines, which cover 23,500 acres, the agriculture of the province is not very important, though 45,500 acres were devoted in 1898 to the culture of wheat, 26,000 to oats, rye, barley, 56,000 acres to pod fruit, and 37,000 to olives. Orange groves yield a good crop. In some parts of the province are pine, cork trees, oaks, chestnuts, and beeches. In 1898 there were 7796 horses, 7963 mules, 13,650 asses, 11,897 cattle, 82,612 sheep, 55,125 goats, and 28,011 pigs. The local industries include 241 manufactories of brandy (*aguardiente*), 78 brickworks, 152 oil mills, 12 soapworks, 18 candle factories, and 360 flour mills. The fisheries also afford a thriving industry, and there are 27 establishments for salting. The principal industry, however, is mining, 307 mines being productive and 717 unproductive. The productive mines, which include 288 copper mines, employed, in 1898, 9108 hands (7875 in the copper mines), and the works connected therewith employed 5078 additional hands. The output included 70,814 tons of sulphur, 15,829 tons of iron ore, 2,229,595 tons of copper ore, 70,000 of iron pyrites, 101,861 of manganese, and 1494 of argentiferous lead. Population (1887), 254,831; (1897), 253,970.

Huelva, capital of the above province. It is a rising and important port, and, with Bilbao and Barcelona, has an increasing trade with Great Britain. There are

few buildings of artistic merit, and the most notable public works are the port improvements, the splendid piers and quays, a bull-ring, the stations, and one of the business offices. The river has a deep channel, but the sandbanks in the river and estuary are serious drawbacks. The shipping returns for 1898 show 1257 vessels of 806,439 tons, 615 of 557,356 tons being British. The export trade in ores is most prosperous, but the wine export has decreased since France raised her scale of duties, the figures for 1898 being 119,836,400 pints, chiefly shipped to France. Among the exports Great Britain took, in 1898, 512,911 tons of cupreous sulphur ore pyrites, 5820 tons of washed ore, 29,972 tons of precipitate of copper, 15,919 of copper mat, 44,924 of iron pyrites, 4179 of manganese, and a considerable amount of corks. Great Britain stands at the head of the imports of manufactured goods, machinery, and breadstuffs, and in 1898 sent 65,768 tons of coal and 13,454 tons of coke. The total of imports during 1899 was 96,508 tons (of 1000 kilos), of which 33 per cent. came from Great Britain, whilst the total of exports for the same period amounted to 1,490,869 tons, 635,431 tons (42 per cent.) being shipped to Great Britain. In 1900 the total of imports was 111,350 tons, 99,252 of which (89 per cent.) were imported from Great Britain. The total of exports amounted to 1,571,257 tons, the total shipped to Great Britain being 622,208 tons (39 per cent.). Population (1887), 18,195; (1897), 19,423.

Huércal-Overa, a town of south-east Spain, in the province of Almeria, not far from the coast. The streets are broad, and there are three fine squares. The parish church has a fine nave and handsome altars. Near Huércal-Overa is the important mining district of Sierra Almagrera. Apart from the product of the mines, the local trade is chiefly agricultural. Population (1887), 15,631; (1897), 16,266.

Huesca, a frontier province of north-east Spain. Its area is 7530 square miles, divided into 8 administrative districts and 362 parishes. The railway from Saragossa to Barcelona runs through the province, and has branches from Tarelimta to Huesca and from Seigna to Barbastro. The Central Pyrenean Railway starts from Zuera on the Saragossa-Barcelona line by the valley of the Gallego, and has been extended to Canfranc, from which it will run to the Somport, the site of the tunnel through the Pyrenees, when France and Spain are in a position to carry out this railway and the Catalonia, Noguera, Pallares, and Ariège line which they undertook to execute simultaneously in 1882. The province of Huesca has 128 miles of first-class roads, and some good provincial and parish roads kept up at local expense. Trade is most active with France, where are sent timber, millstones, cattle, leather, brandy, and, above all, wine. The vineyards were quickly developed from 1882 to 1892, in the heyday of the exports of common red wines to France, but have much declined since. The forests of the Pyrenean region afford one of the most flourishing local industries, pine, fir, oak, and beech forests giving annually £160,000 worth of excellent timber. In some districts irrigation fertilized many thousand acres. The mineral resources remain almost entirely undeveloped. In 1898 there were 4864 horses, 44,170 mules, 30,796 asses, 45,611 cattle, 443,517 sheep, 83,348 goats, and 43,868 pigs. Agriculture is progressing owing to the enterprising spirit of the inhabitants. No less than 352,000 acres were devoted in 1898 to wheat, 30,000 acres to rye, oats, barley, and maize, 14,000 acres to pod fruit, 141,000 acres to vines, and 39,000 acres to olives. There is some emigration. Population (1897), 247,317.

Huesca, the capital of the above province. Considerable attention is paid to public education, and there are not only several good primary schools, but normal schools for teachers, an institute, a seminary, an artistic and archæological museum, and an economical society. A few manufactures and an active trade in agricultural products and wines have kept up its importance, despite the decline of its population consequent on emigration to France. Population (1887), 13,043; (1897), 11,204.

Huet. See Busken-Huet.

Huggins, Sir William (1824– ——), English astronomer, was born in London on 7th February 1824, and was educated first at the City of London School and then under various private teachers. Having determined to apply himself to the study of astronomy, he built a private observatory for that purpose at Tulse Hill, in the south of London, about 1855. At first he occupied himself with routine work on the ordinary lines followed by astronomers of the day, but he was far from satisfied with the scope which this afforded, and therefore seized eagerly upon the opportunity for research in a new direction which was offered by Kirchhoff's discoveries in spectrum analysis. The chemical constitution of the stars was the problem to which he turned his attention, and his first results, obtained in conjunction with Professor W. A. Miller, were presented to the Royal Society in 1863, in a preliminary note on the "Lines of some of the fixed stars." At the same time, by making use of photography, he introduced into the methods of astronomy an innovation which was destined ultimately to exert as potent an influence on the progress of the science as spectroscopy itself. Wet collodion was, however, the only process at first available, and the difficulties involved in its application to astronomical purposes were so enormous that it was used only to a very limited extent; the real triumphs of photographic astronomy began about 1875 with the invention of the gelatine dry plate. This enabled the observer to make his exposures as long as he might desire, and, through the cumulative action of light on his extremely sensitive surfaces, to obtain permanent accurate pictures of celestial objects which are so faint as to be completely invisible to the eye, even when aided by the most powerful telescopes. In the last quarter of the 19th century spectroscopy and photography together worked a revolution in the science of observational astronomy, and in the utilization of both Huggins acted as pioneer. Besides these new methods, many results of great importance are associated with his name. Thus in 1864 the spectroscope yielded him evidence that the planetary nebula in Draco consists of luminous gas—a conclusion confirming the nebular hypothesis and supporting the belief that such nebulæ are surviving relics of the mass of glowing gas from which Laplace supposed the solar system to have been formed by condensation. Four years afterwards the same instrument enabled Huggins to prove the existence of carbon in comets; and about the same time he showed how by the application of Doppler's principle it can be used not only to detect the motion of stars moving in the line of vision, but even to measure its amount with more or less accuracy. Such data, which the astronomer can scarcely gain in any other way, are obviously indispensable to any adequate conception of the arrangement of the stars in space. In solar physics Huggins suggested a spectroscopic method by which the red prominences of the sun may be viewed at any time, even when it is not eclipsed, and one of his experiments went far towards settling a much-disputed question regarding the solar distribution of calcium. In the general solar spectrum

this element is represented by a large number of lines, but in the spectrum of the prominences and chromosphere only one pair of these can be detected. This circumstance has seemed so anomalous to some astronomers that they have doubted whether the pair of lines in question is due to calcium at all, but Sir William and Lady Huggins (who, after their marriage in 1875, actively assisted her husband in his scientific work) dispelled this doubt by demonstrating in the laboratory that calcium vapour, if at a sufficiently low pressure, gives under the influence of the electric discharge precisely these lines and no others. Sir William Huggins, who was made K.C.B. in 1897, has received many honours, academic and other. He presided over the meeting of the British Association in 1891, and in 1900 was chosen president of the Royal Society, from which he has at different times received a Royal, a Copley, and a Rumford medal. He is the author of many scientific papers and (with Lady Huggins) of a magnificent *Atlas of Representative Stellar Spectra*, published in 1900, which gained the Actonian prize of the Royal Institution.

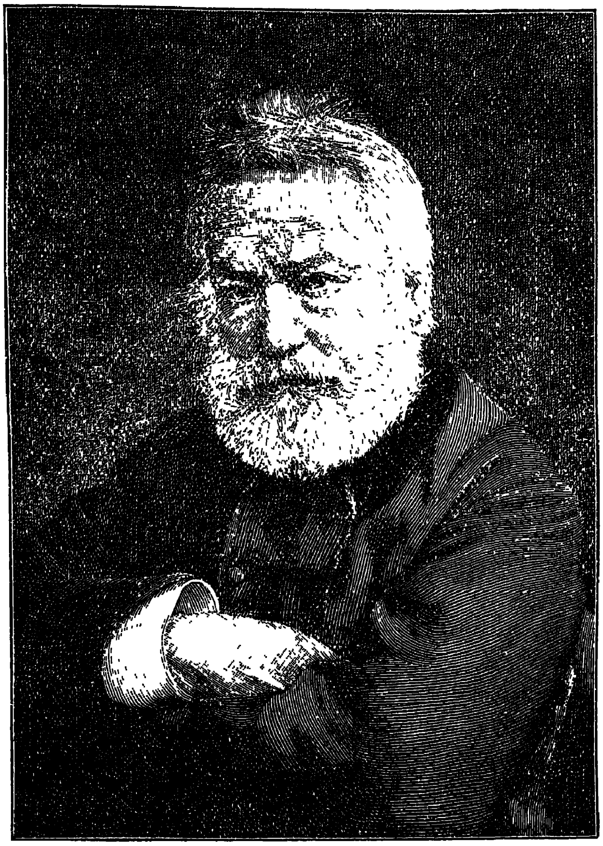
Hughes, David Edward (1831–1900), Anglo-American electrician, was born on 16th May 1831 in London, but the earlier part of his life was spent in America, whither his parents emigrated when he was about seven years old. In 1850 he became professor of music at the college of Bardstown, Kentucky, and soon afterwards his attainments in physical science procured his appointment as professor of natural philosophy at the same place. His professorial career, however, was brief, for in 1854 he removed to Louisville to supervise the manufacture of the type-printing telegraph instrument which he had been thinking out for some time, and which was destined to make both his name and his fortune. The patent for this machine was taken out in the United States in 1855, and its success was immediate. (For a description, see *Ency. Brit.* vol. xxiii. p. 121.) About the period when it was invented the Morse system, under the control of the American Telegraph Company, held the field in the United States, and the new instrument was promptly taken up as a means to fight what were regarded as the excessive rates charged by that company. After seeing it well established on one side of the Atlantic, Hughes in 1857 brought it over to his native country, where, however, the telegraph companies did not receive it with any favour. Two or three years afterwards he introduced it to the notice of the French Government, who, after submitting it to severe tests, ultimately adopted it, and in the succeeding ten years it came into extensive use all over Europe, gaining for its inventor numerous honours and prizes. In the development of telephony also Hughes had an important share, and the telephone has attained its present perfection largely as a result of his investigations. The carbon transmitters which in various forms are in almost universal use are modifications of a simple device which he called a microphone, and which consists essentially of two pieces of carbon, one resting lightly on the other. The arrangement constitutes a variable electrical resistance of the most delicate character; if it is included in an electric circuit with a battery and subjected to the influence of sonorous vibrations, its resistance varies in such a way as to produce an undulatory current which affords an exact representation of the sound waves as to height, length, and form. These results were published in 1878, but Hughes did much more work on the properties of such microphonic joints, of which he said nothing till many years afterwards. When towards the end of 1879 he found that they were also sensitive to "sudden electric impulses, whether given out to the atmosphere through the extra current from a coil or from a frictional machine," he in fact discovered the phenomena on which depends the action of the so-called "coherers" that form an indispensable adjunct to wireless telegraphy. But he went further and practised wireless telegraphy himself, surmising, moreover, that the agency he was employing consisted of true electric waves. Setting some source of the "sudden electric impulses" referred to above into operation in his house, he walked along the street carrying a telephone in circuit with a small battery and one of these microphonic joints, and found that the sounds remained audible in the telephone until he had traversed a distance of 500 yards. This experiment he showed to several English men of science, among others to Sir G. G. Stokes, to whom he broached the theory that the results were due to electric waves. That physicist, however, was not disposed to accept this explanation, considering that a sufficient one could be found in well-known electromagnetic induction effects, and Hughes was so discouraged at that high authority taking this view of the matter that he resolved to publish no account of his inquiry until further experiments had enabled him to prove the correctness of his own theory. These experiments were still in progress when Hertz settled the question by his researches on electric waves in 1887–89. Hughes, who is also known for his invention of the induction balance and for his contributions to the theory of magnetism, died in London on 22nd January 1900. As an investigator he was remarkable for the extraordinary simplicity of the apparatus which served his purposes, domestic articles like jam-pots, pins, &c., forming a large part of the equipment of his laboratory. His manner of life, too, was simple and frugal in the extreme. At his death he was possessed of property worth not much less than half a million sterling, and the whole of this immense sum, with the exception of some bequests to the Royal Society, the Paris Academy of Sciences, the Institution of Electrical Engineers, and the Paris Société Internationale des Électriciens, for the establishment of scholarships and prizes in physical science, was left to four London hospitals, subject only to the payment of life annuities to certain of his relatives. (H. M. R.)

Hughes, Thomas (1822–1896), English lawyer and author, second son of John Hughes of Donnington Priory, editor of *The Boscobel Tracts* (1830), was born at Uffington, Berks, on 20th October 1822. In February 1834 he went to Rugby School, to be under Dr Arnold, a contemporary of his father at Oriel. He rose steadily to the sixth form, where he came into contact with the headmaster whom he afterwards idealized; but he excelled rather in sports than in scholarship, and his school career culminated in a cricket match at Lord's. In 1842 he proceeded to Oriel, Oxford, and graduated B.A. in 1845. He was called to the bar in 1858, became Q.C. in 1869, a bencher in 1870, and was appointed to a county court judgeship in the Chester district in July 1882. While at Lincoln's Inn he came under the dominating influence of his life, that of Frederick Denison Maurice. In 1848 he joined the Christian Socialists, under Maurice's banner, among his closest allies being Charles Kingsley. In January 1854 he was one of the original promoters of the Working Men's College in Great Ormond Street, and whether he was speaking on sanitation, sparring, or singing his favourite ditty of "Little Billee," his work there continued one of his chief interests to the end of his life. After Maurice's death he held the principalship of the college. His *Manliness of Christ* (1879) grew out of a Bible-class which he held there. Hughes had been influenced mentally by Arnold, Carlyle, Thackeray, Lowell,

and Maurice, and had developed into a liberal churchman, extremely religious, with strong socialistic leanings; but the substratum was still and ever the manly country squire of old-fashioned, sport-loving England. In Parliament, where he sat for Lambeth (1865–68), and for Frome (1868–74), he reproduced some of the traits of Colonel Newcome. Thrice he visited America and received a warm welcome, less as a propagandist of social reform than as a friend of Lowell and of the North, and an author. In 1879, in a sanguine humour worthy of Mark Tapley, he planned a co-operative settlement, "Rugby," in Tennessee, over which he lost money. In 1848 Hughes had married Frances, niece of Richard Ford, of Spanish *Handbook* fame. They settled in 1853 at Wimbledon, and there was written his famous story, *Tom Brown's School Days*, "by an Old Boy" (dedicated to Mrs Arnold of Fox Howe), which came out in April 1857. It is probably impossible to depict the schoolboy in his natural state and in a realistic manner; it is extremely difficult to portray him at all in such a way as to interest the adult. Yet this last has certainly been achieved twice in English literature—by Dickens in *Nicholas Nickleby*, and by Hughes in *Tom Brown*. In both cases interest is concentrated upon the master, in the first a demon, in the second a demigod. *Tom Brown* did a great deal to fix the English concept of what a public school should be. Hughes also wrote *The Scouring of the White Horse* (1859), *Tom Brown at Oxford* (1861), *Religio Laici* (1868), and the *Memoir of a Brother*. The brother was George Hughes, who was in the main the original "Tom Brown," just as Dean Stanley was in the main the original of "Arthur." Hughes died at Brighton, on 22nd March 1896. He was English of the English, full of "muscular Christianity," straightforward and unsuspicious to a fault, yet attaching a somewhat exorbitant value to "earnestness"—a favourite expression of Doctor Arnold. (T. SE.)

Hugo, Victor Marie (1802–1885), the great French poet, dramatist, and romance-writer, was born at Besançon on the 26th of February 1802. The all but still-born child was only kept alive and reared by the indefatigable devotion of his mother, a royalist of La Vendée married to a general in the service of Napoleon. Educated first in Spain and afterwards in France, the boy whose infancy had followed the fortunes of the imperial camp grew up a royalist and a Catholic. His first work in poetry and in fiction was devoted to the passionate proclamation of his faith in these principles. The precocious eloquence and ardour of these early works made him famous before his time. The odes which he published at the age of twenty, admirable for their spontaneous fervour and fluency, might have been merely the work of a marvellous boy; the ballads which followed them two years later revealed him as a great poet, a natural master of lyric and creative song. In 1823, at the age of twenty-one, he married his cousin Adèle Foucher. In the same year his first romance, *Han d'Islande*, was given to the press; his second, *Bug-Jargal*, appeared three years later. In 1827 he published the great dramatic poem of *Cromwell*, a masterpiece at all points except that of fitness for the modern stage. Two years afterwards he published *Les Orientales*, a volume of poems so various in style, so noble in spirit, so perfect in workmanship, in music, and in form, that they might alone suffice for the foundation of an immortal fame. In the course of nine years, from 1831 to 1840, he published *Les Feuilles d'Automne*, *Les Chants du Crépuscule*, *Les Voix Intérieures*, and *Les Rayons et les Ombres*. That their author was one of the greatest elegiac and lyric poets ever born into the world, any one of these volumes would amply suffice to prove. That he was the greatest tragic and dramatic poet born since the age of Shakespeare, the appearance of *Hernani* in 1830 made evident for ever to all but the meanest and most perverse of dunces and malignants. The earlier and even greater tragedy of *Marion de Lorme* had been proscribed on the ground that it was impossible for royalty to tolerate the appearance of a play in which a king was represented as the puppet of a minister. In all the noble and glorious life of the greatest poet of his time there is nothing on record more chivalrous and characteristic than the fact that Victor Hugo refused to allow the play which had been prohibited by the Government of Charles X. to be instantly produced under the Government of his supersessor. *Le Roi s'amuse*, the next play which Hugo gave to the stage, was prohibited by order of Louis Philippe after a tumultuous first night—to reappear again fifty years later on the same day of the same month, under the eyes of its author, with atoning acclamation from a wider audience than the first. Terror and pity had never found word or expression on the stage which so exactly realized the ideal aim of tragic poetry among the countrymen of Æschylus and Sophocles since the time or since the passing of Shakespeare, of Marlowe, and of Webster. The tragedy of *Lucrèce Borgia*, coequal in beauty and power with its three precursors, followed them next year in the humbler garb of prose; but the prose of Victor Hugo stands higher on the record of poetry than the verse of any lesser dramatist or poet. *Marie Tudor*, his next play, was hardly more daring in its Shakespearean defiance of historic fact, and hardly more triumphant in its Shakespearean loyalty to the everlasting truth of human character and passion. *Angelo, Tyran de Padoue*, the last of the tragic triad to which their creator denied the transfiguration of tragic verse, is inferior to neither in power of imagination and of style, in skill of invention and construction, and in mastery over all natural and noble sources of pity and of terror. *La Esmeralda*, the libretto of an opera founded on his great tragic romance of *Notre-Dame de Paris*, is a miracle of lyric melody and of skilful adaptation. *Ruy Blas*, his next play, was written in verse, and in such verse as none but he could write. In command and in expression of passion and of pathos, of noble and of evil nature, it equals any other work of this great dramatic poet; in the lifelike fusion of high comedy with deep tragedy it excels them all. *Les Burgraves*, a tragic poem of transcendent beauty in execution and imaginative audacity in conception, found so little favour on the stage that the author refused to submit his subsequent plays to the verdict of a public audience. His first mature work in prose fiction, *Le Dernier Jour d'un Condamné*, had appeared thirteen years earlier. As a tragic monodrama it is incomparable for sustained power and terrible beauty. The story of *Claude Gueux*, published five years later, another fervent protest against the infliction of capital punishment, was followed by many other eloquent and passionate appeals to the same effect, written or spoken on various occasions which excited the pity or the indignation of the orator or the poet. In 1831 appeared the greatest of all tragic or historic or romantic poems in the form of prose narrative, *Notre-Dame de Paris*. Three years afterwards the author published, under the title of *Littérature et Philosophie mêlées*, a compilation or selection of notes and essays ranging and varying in date and in style from his earliest effusions of religious royalism to the magnificent essay on Mirabeau which represents at once the historical opinion and the critical capacity of Victor Hugo at the age of thirty-two. Next year he published *Le Rhin*, a series of letters from Germany, brilliant and vivid beyond all comparison, containing one of the most splendid stories for children ever written, and

followed by a political supplement rather pathetically unprophetic in its predictions. At the age of thirty-eight he honoured the French Academy by taking his place among its members; the speech delivered on the occasion was characteristically generous in its tribute to an undeserving memory, and significantly enthusiastic in its glorification of Napoleon. Idolatry of his father's hero and leader had now superseded the earlier superstition inculcated by his mother. In 1846 his first speech in the chamber of peers —Louis Philippe's House of Lords—was delivered on behalf of Poland; his second, on the subject of coast defence, is memorable for the evidence it bears of careful research and practical suggestion. His pleading on behalf of the exiled family of Bonaparte induced Louis Philippe to cancel the sentence which excluded its members from France. After the fall and flight of the house of Orleans, his parliamentary eloquence was never less generous in aim and always as fervent in its constancy to patriotic and progressive principle. When the conspiring forces of clerical venality and political prostitution had placed a putative Bonaparte in power attained by perjury after perjury, and supported by massacre after massacre, Victor Hugo, in common with all honourable men who had ever taken part in political or public life under the government superseded by force of treason and murder, was driven from his country into an exile of well-nigh twenty years. Next year he published *Napoléon le Petit;* twenty-five years afterwards, *Histoire d'un Crime.* In these two books his experience and his opinion of the tactics which founded the second French empire stand registered for all time. In the deathless volume of *Châtiments,* which appeared in 1853, his indignation, his genius, and his faith found such utterance and such expression as must recall to the student alternately the lyric inspiration of Coleridge and Shelley, the prophetic inspiration of Dante and Isaiah, the satiric inspiration of Juvenal and Dryden. Three years after *Les Châtiments,* a book written in lightning, appeared *Les Contemplations,* a book written in sunlight and starlight. Of the six parts into which it is divided, the first translates into many-sided music the joys and sorrows, the thoughts and fancies, the studies and ardours and speculations of youth; the second, as full of light and colour, grows gradually deeper in tone of thought and music; the third is yet riper and more various in form of melody and in fervour of meditation; the fourth is the noblest of all tributes ever paid by song to sorrow — a series of poems consecrated to the memory of the poet's eldest daughter, who was drowned together with her husband by the upsetting of a boat off the coast of Normandy, a few months after their wedding-day, in 1843; the fifth and the sixth books, written during his first four years of exile (all but one noble poem which bears date nine years earlier than its epilogue or postscript), contain more than a few poems unsurpassed and unsurpassable for depth and clarity and trenchancy of thought, for sublimity of inspiration, for intensity of faith, for loyalty in translation from nature, and for tenderness in devotion to truth; crowned and glorified and completed by their matchless dedication to the dead. Three years later again, in 1859, Victor Hugo gave to the world the first instalment of the greatest book published in the 19th century, *La Légende des Siècles.* Opening with a vision of Eve in Paradise which eclipses Milton's in beauty no less than in sublimity—a dream of the mother of mankind at the hour when she knew the first sense of dawning motherhood, it closes with a vision of the trumpet to be sounded on the day of judgment which transcends the imagination of Dante by right of a realized idea which was utterly impossible of conception to a believer in Dante's creed: the idea of real and final equity; the concept of absolute and abstract righteousness. Between this opening and this close the pageant of history and of legend, marshalled and vivified by the will and the hand of the poet, ranges through an infinite variety of action and passion, of light and darkness, of terror and pity, of lyric rapture and of tragic triumph. After yet another three years' space the author of *La Légende des Siècles* reappeared as the author of *Les Misérables,* the greatest epic and dramatic work of fiction ever created or conceived: the epic of a soul transfigured and redeemed, purified by heroism and glorified through suffering; the tragedy and the comedy of life at its darkest and its brightest, of humanity at its best and at its worst. Two years afterwards the greatest man born since the death of Shakespeare paid homage to the greatest of his predecessors in a volume of magnificent and discursive eloquence which bore the title of *William Shakespeare,* and might, as its author admitted and suggested, more properly have been entitled *À propos de Shakespeare.* It was undertaken with the simple design of furnishing a preface to his younger son's translation of Shakespeare; a monument of perfect scholarship, of indefatigable devotion, and of literary genius, which eclipses even Urquhart's Rabelais—its only possible competitor; and to which the translator's father prefixed a brief and admirable note of introduction in the year after the publication of the volume which had grown under his hand into the bulk and the magnificence of an epic poem in prose. In the same year *Les Chansons des Rues et des Bois* gave evidence of new power and fresh variety in the exercise and display of an unequalled skill and a subtle simplicity of metre and of style employed on the everlasting theme of lyric and idyllic fancy, and touched now and then with a fire more sublime than that of youth and love. Next year the exile of Guernsey published his third great romance, *Les Travailleurs de la*



VICTOR HUGO.
(*From a photograph by P. Nadar, Paris*)

Mer, a work unsurpassed even among the works of its author for splendour of imagination and of style, for pathos and sublimity of truth. Three years afterwards the same theme was rehandled with no less magnificent mastery in *L'Homme qui Rit;* the theme of human heroism confronted with the superhuman tyranny of blind and unimaginable chance, overpowered and unbroken, defeated and invincible. Between the dates of these two great books appeared *La Voix de Guernesey*, a noble and terrible poem on the massacre of Mentana which branded and commemorated for ever the papal and imperial infamy of the colleagues in that crime. In 1872 Victor Hugo published in imperishable verse his record of the year which followed the collapse of the empire, *L'Année Terrible.* All the poet and all the man spoke out and stood evident in the perfervid patriotism, the filial devotion, the fatherly tenderness, the indignation and the pity, which here find alternate expression in passionate and familiar and majestic song. In 1874 he published his last great romance, the tragic and historic poem in prose called *Quatrevingt-treize;* a work as rich in thought, in tenderness, in wisdom and in humour and in pathos, as ever was cast into the mould of poetry or of fiction. The introduction to his first volume of *Actes et Paroles*, ranging in date from 1841 to 1851, is dated in June 1875; it is one of his most earnest and most eloquent appeals to the conscience and intelligence of the student. The second volume contains the record of his deeds and words during the years of his exile; like the first and the third, it is headed by a memorable preface, as well worth the reverent study of those who may dissent from some of the writer's views as of those who may assent to all. The third and fourth volumes preserve the register of his deeds and words from 1870 to 1885; they contain, among other things memorable, the nobly reticent and pathetic tribute to the memory of the two sons he had lost since their common return from exile. In 1877 appeared the second series of *La Légende des Siècles;* and in the same year the author of that colossal work, treating no less of superhuman than of human things, gave us the loveliest and most various book of song on the loveliest and simplest of subjects ever given to man, *L'Art d'être Grandpère.* Next year he published *Le Pape*, a vision of the spirit of Christ in appeal against the spirit of Christianity, His ideal follower confronted and contrasted with His nominal vicar; next year again *La Pitié Suprême*, a plea for charity towards tyrants who know not what they do, perverted by omnipotence and degraded by adoration; two years later *Religions et Religion*, a poem which is at once a cry of faith and a protest against the creeds which deform and distort and leave it misshapen and envenomed and defiled; and in the same year *L'Âne*, a pæan of satiric invective against the past follies of learned ignorance, and lyric rapture of confidence in the future wisdom and the final conscience of the world. These four great poems, one in sublimity of spirit and in supremacy of style, were succeeded next year by a fourfold gift of even greater price, *Les Quatre Vents de l'Esprit:* the first book, that of satire, is as full of fiery truth and radiant reason as any of his previous work in that passionate and awful kind; the second or dramatic book is as full of fresh life and living nature, of tragic humour and of mortal pathos, as any other work of the one great modern dramatist's; the third or lyric book would suffice to reveal its author as incomparably and immeasurably the greatest poet of his age, and one great among the greatest of all time; the fourth or epic book is the sublimest and most terrible of historic poems—a visionary pageant of French history from the reign and the revelries of Henry IV. to the reign and the execution of Louis XVI. Next year the great tragic poem of *Torquemada* came forth to bear witness that the hand which wrote *Ruy Blas* had lost nothing of its godlike power and its matchless cunning, if the author of *Le Roi s'amuse* had ceased to care much about coherence of construction from the theatrical point of view as compared with the perfection of a tragedy designed for the devotion of students not unworthy or incapable of the study; that his command of pity and terror, his powers of intuition and invention, had never been more absolute and more sublime; and that his infinite and illimitable charity of imagination could transfigure even the most monstrous historic representative of Christian or Catholic diabolatry into the likeness of a terribly benevolent and a tragically magnificent monomaniac. Two years later Victor Hugo published the third and concluding series of *La Légende des Siècles.* On the 22nd of May 1885 he died. The first volume published of his posthumous works was the exquisite and splendid *Théâtre en Liberté*, a sequence if not a symphony of seven poems in dramatic form, tragic or comic or fanciful eclogues, incomparable with the work of any other man but the author of *The Tempest* and *The Winter's Tale* in combination and alternation of gayer and of graver harmonies. The unfinished poems, *Dieu* and *La Fin de Satan*, are full to overflowing of such magnificent work, such wise simplicity of noble thought, such heroic and pathetic imagination, such reverent and daring faith, as no other poet has ever cast into deathless words and set to deathless music. *Les Jumeaux*, an unfinished tragedy, would possibly have been the very greatest of his works if it had been completed on the same scale and on the same lines as it was begun and carried forward to the point at which it was cut short for ever. His reminiscences of "Things Seen" in the course of a strangely varied experience, and his notes of travel among the Alps and Pyrenees, in the north of France and in Belgium, in the south of France and in Burgundy, are all recorded by such a pen and registered by such a memory as no other man ever had at the service of his impressions or his thoughts. *Toute la Lyre*, his latest legacy to the world, would be enough, though no other evidence were left, to show that the author was one of the very greatest among poets and among men; unsurpassed in sublimity of spirit, in spontaneity of utterance, in variety of power, and in perfection of workmanship; infinite and profound beyond all reach of praise at once in thought and in sympathy, in perception and in passion; master of all the simplest as of all the subtlest melodies or symphonies of song that ever found expression in a Border ballad or a Pythian ode. (A. C. S.)

Hulke, John Whitaker (1830–1895), British surgeon and geologist, was born 6th November 1830, being the son of a well-known medical practitioner at Deal. He was educated at King's College School and Hospital (M.R.C.S. 1852, F.R.C.S. 1857). After the death of the duke of Wellington in 1854, young Hulke, who had attended with his father on the occasion, wrote the official description for the newspapers. In the Crimean War he volunteered, and was appointed assistant-surgeon at Smyrna, and subsequently at Sebastopol. On returning home he became medical tutor at his old hospital, and afterwards assistant-surgeon. Hulke was an excellent general surgeon, but made his special mark as an ophthalmologist, and as a geologist he had a European reputation. He was president of both the Geological and Pathological Societies in 1883, and president of the Royal College of Surgeons from 1893 until his death on 19th February 1895.

Hull, or Kingston-upon-Hull, a municipal borough (extended 1882 and 1897), city, county, and parliamentary

borough and seaport of Yorkshire, England, a county in itself, at the influx of the Hull into the estuary of the Humber, 174½ miles by rail north of London. The corporation consists of a mayor, 16 aldermen, and 48 councillors. There are also a high steward, a recorder, and a sheriff. In 1885 the parliamentary representation was increased from 2 to 3 members, and the municipal and the parliamentary boroughs were made co-extensive. In 1888 Hull became a county borough, and in 1891 the seat of a bishop-suffragan to the archdiocese of York. There are over 20 parish and district, and 4 Roman Catholic churches, and numerous Nonconformist chapels. Erections since 1881 include the pier (reconstructed), the new river wall, a promenade pier, a technical school, a municipal crematorium, 4 public libraries, a market hall, a dispensary, a sanatorium, a smallpox hospital, municipal almshouses, 2 theatres, Hymer's College, comprising classical, modern, and junior departments, and a grammar school. Among the many board schools are 3 of higher grade, one of them accommodating 600 boys and 520 girls. The West Park was opened in 1885, the East Park in 1887. There are 3 daily newspapers. In 1888 the ports of Hull and Goole were administratively combined, the Hull docks measuring about 186 acres, the Goole docks 30 acres. Docks more recently opened are the Alexandra dock (1883), with 53½ acres of water area, 160 acres of quayage, and 2 graving docks; St Andrew's (1883), the fish dock, since extended. The railway to near Barnsley (1885) gives Hull direct communication with the South Yorkshire coal-fields. The registered shipping in 1889 was 835 vessels of 220,923 tons; in 1899, 867 of 228,395 tons. Entrances in 1889 numbered 5414 vessels of 2,439,617 tons; clearances, 5224 vessels of 2,401,391 tons: entrances in 1899 numbered 6246 of 3,115,748 tons; clearances, 6086 vessels of 3,045,991 tons. Imports of foreign and colonial merchandise were valued in 1899 at £28,822,898, against £26,288,229 in 1889. Exports of the produce and manufactures of the United Kingdom were valued in 1899 at £16,648,793, against £16,768,144 in 1889. Area, 8172 acres. Population (1891), 200,472; (1901), 240,618.

Hull, a city (1875) and railway junction of Quebec, Canada, and the capital of Wright county, opposite the city of Ottawa. The Chaudière Falls of the Ottawa furnish magnificent water-power, which is utilized by the extensive saw-mills, pulp, paper, and match manufactories. Hull contains a convent, three churches, a court-house, and a town hall. Population (1881), 6890; (1901), 13,988.

Hullah, John Pyke (1812–1884), English composer and teacher of music, was born at Worcester, 27th June 1812. He was a pupil of William Horsley from 1829, and entered the Royal Academy of Music in 1833. He wrote an opera to words by Dickens, *The Village Coquettes*, produced in 1836; *The Barbers of Bassora* in 1837, and *The Outpost* in 1838, the last two at Covent Garden. From 1839, when he went to Paris to investigate various systems of teaching music to large masses of people, he identified himself with Wilhem's system of the "fixed Do," and his adaptation of that system was taught with enormous success from 1840 to 1860. In 1847 a large building in Long Acre, called St Martin's Hall, was built by subscription and presented to Hullah. It was inaugurated in 1850 and burnt to the ground in 1860, a blow from which Hullah was long in recovering. He had risked his all in the maintenance of the building, and had to begin the world again. A series of lectures was given at the Royal Institution in 1861, and in 1864 he lectured in Edinburgh, but in the following year was unsuccessful in his application for the Reid professorship. He conducted concerts in Edinburgh in 1866 and 1867, and the concerts of the Royal Academy of Music from 1870 to 1873; he had been elected to the committee of management in 1869. In 1872 he was appointed by the Council of Education musical inspector of training schools for the United Kingdom. In 1878 he went abroad to report on the condition of musical education in schools, and wrote a very valuable report, quoted in the memoir of him published by his wife in 1886. He was attacked by paralysis in 1880, and again in 1883. His compositions, which remained popular for some years after his death, consisted mainly of ballads of a fairly artistic order; but his importance in the history of music is owing to his exertions in popularizing musical education, and his persistent opposition to the Tonic Sol-Fa system, which had a success he could not foresee. His objections to it were partly grounded on the character of the music which was in common use among the early teachers of the system. While it cannot be doubted that Hullah would have won more success if he had not opposed the Tonic Sol-Fa movement so strenuously, it must be confessed that his work was of great value, for he kept constantly in view and impressed upon all who followed him or learnt from him the supreme necessity of maintaining the artistic standard of the music taught and studied, and of not allowing trumpery compositions to usurp the place of good music on account of the greater ease with which they could be read. (J. A. F. M.)

Humacao, a small city near the south-east corner of the island of Porto Rico, 31 miles south-east of San Juan. It is the capital of a province of the same name. Population, 4428.

Humbert, Ranieri Carlo Emanuele Giovanni Maria Ferdinando Eugenio, King of Italy (1844–1900), son of Victor Emmanuel II. and of Adelaide, archduchess of Austria, was born at Turin, capital of the kingdom of Sardinia, on 14th March 1844. His education was entrusted to the most eminent men of his time, amongst others to Massimo d'Azeglio and Pasquale Stanislao Mancini. Entering the army on 14th March 1858 with the rank of captain, he was present at the battle of Solferino in 1859, and in 1866 commanded a division at Custozza. Attacked by the Austrian cavalry near Villafranca, he formed his troops into squares and drove the assailants towards Sommacampagna, remaining himself throughout the action in the square most exposed to attack. With Bixio he covered the retreat of the Italian army, receiving the gold medal for valour. On 21st April 1868 he married his cousin, Margherita Teresa Giovanna, princess of Savoy, daughter of the duke of Genoa (born at Turin on 20th November 1851). On 11th November 1869 Margherita gave birth to Victor Emmanuel, prince of Naples, afterwards Victor Emmanuel III. of Italy. Ascending the throne on the death of his father (9th January 1878), Humbert adopted the style "Humbert I. of Italy" instead of Humbert IV., and consented that the remains of his father should be interred at Rome in the Pantheon, and not in the royal mausoleum of Superga. Accompanied by the premier, Cairoli, he began a tour of the provinces of his kingdom, but on entering Naples (17th November 1878), amid the acclamations of an immense crowd, was attacked by a fanatic named Passanante. The king warded off the blow with his sabre, but Cairoli, in attempting to defend him, was severely wounded in the thigh. The would-be assassin was condemned to death, but the sentence was by the king commuted to one of penal servitude for life. The occurrence upset for several years the health of Queen

Margherita. In 1881 King Humbert, again accompanied by Cairoli, resumed his interrupted tour, and visited Sicily and the southern Italian provinces. In 1882 he took a prominent part in the national mourning for Garibaldi, whose tomb at Caprera he repeatedly visited. When, in the autumn of 1882, Verona and Venetia were inundated, he hastened to the spot, directed salvage operations, and provided large sums of money for the destitute. Similarly, on 28th July 1883, he hurried to Ischia, where an earthquake had engulfed some 5000 persons. Countermanding

King Humbert.
(From a photograph by Giacomo Brogi, Florence.)

the order of the minister of public works to cover the ruins with quicklime, the king prosecuted salvage operations for five days longer, and personally saved many victims at the risk of his own life. In 1884 he visited Busca and Naples, where cholera was raging, helping with money and advice the numerous sufferers, and raising the spirit of the population. Compared with the reigns of his grandfather, Charles Albert, and of his father, Victor Emmanuel, the reign of Humbert was tranquil. Scrupulously observant of constitutional principles, he followed, as far as practicable, parliamentary indications in his choice of premiers, only one of whom—Rudinì—was drawn from the Conservative ranks. In foreign policy he approved of the conclusion of the Triple Alliance, and, in repeated visits to Vienna and Berlin, established and consolidated the pact. Towards Great Britain his attitude was invariably cordial, and he considered the Triple Alliance imperfect unless supplemented by an Anglo-Italian naval *entente*. Favourably disposed towards the policy of colonial expansion inaugurated in 1885 by the occupation of Massawa, he was suspected of aspiring to a vast empire in North-east Africa, a suspicion which tended somewhat to diminish his popularity after the disaster of Adowa on 1st March 1896. On the other hand, his popularity was enhanced by the firmness of his attitude towards the Vatican, as exemplified in his telegram declaring Rome "intangible" (20th September 1886), and affirming the permanence of the Italian possession of the Eternal City. Above all King Humbert was a soldier, jealous of the honour and prestige of the army to such a degree that he promoted a duel between his nephew, the count of Turin, and Prince Henry of Orleans (15th of August 1897) on account of the aspersions cast by the latter upon Italian arms. The claims of King Humbert upon popular gratitude and affection were enhanced by his extraordinary munificence, which was not merely displayed on public occasions, but directed to relieve innumerable private wants into which he had made personal inquiry. It has been calculated that at least £100,000 per annum was expended by the king in this way. The regard in which he was universally held was abundantly demonstrated on the occasion of the unsuccessful attempt upon his life made by the anarchist Acciarito near Rome on 22nd April 1897, and still more after his tragic assassination at Monza by the anarchist Bresci on the evening of 29th July 1900. Good-humoured, active, tender-hearted, somewhat fatalistic, but, above all, generous, he was spontaneously called "Humbert the Good." He was buried in the Pantheon in Rome, by the side of Victor Emmanuel II., on 9th August 1900. (H. W. S.)

Hungary (Magyarország), one of the two states constituting the monarchy of Austria-Hungary (*q.v.*). The kingdom includes Hungary proper and the province of Croatia-Slavonia, the latter enjoying to a large extent autonomy, granted by the so-called compromise of 1868, which regulated the legal relation of Croatia-Slavonia-Dalmatia to the mother-country. The town and district of Fiume, though united with Hungary proper in respect of administration, enjoys autonomy to a greater extent than the other cities endowed with municipal rights. In the present article the kingdom will be treated of mainly as a whole, as statistics of many of the subjects dealt with cannot be obtained for the separate divisions. In 1873 part of the "Military Frontier" mentioned in the ninth edition of the *Encyclopædia Britannica* was united with Hungary proper and part with Croatia-Slavonia. As Transylvania is a mere historical expression, it will always be included in the territory of Hungary proper, as will Fiume also.

Climate.—With only a very small strip of coast-line, Hungary has a continental climate—cold in winter, hot in summer. The rainfall is in general low, except in the mountainous districts. The following table gives the mean temperature (centigrade), relative humidity, and rainfall (including snow) at a series of meteorological stations during the years 1896–1900 :—

Stations.	Metres above Sea.	Mean Temperature. Annual.	January.	July.	Relative Humidity.	Rainfall in Millimetres.
Selmeczbánya	621	7·9	–2·3	18·2	79	905
Budapest	153	10·5	–0·7	20·4	76	616
Keszthely	133	11·4	–1·1	21·9	78	684
Zágráb	163	11·3	1·3	21·4	72	880
Fiume	5	13·8	6·4	22·6	75	1805
Debreczen	129	10·1	–1·9	21·1	79	571
Szeged	95	10·9	–0·5	21·7	80	656
Nagyszeben	414	9·4	–3·4	20·6	79	735

Except at Fiume, the temperature at all these stations in the winter is below freezing-point, and the mean rainfall below 900 millimetres. The mountain-stations, Selmeczbánya in the northern and Nagyszeben in the south-eastern Carpathians, enjoy a more humid and, in the summer, a more temperate climate than the large plain called Alföld,

of which Debreczen and Szeged may be regarded as representative towns.

Area and Population.—The area of the kingdom of Hungary is:

	English Square Miles.
Hungary proper	108,982
Croatia-Slavonia	16,420
Total	125,402

For administrative purposes the territories belonging to the Hungarian Crown (St Stephen's Crown) are divided into municipalities (counties) endowed with a certain amount of self-government. Hungary proper is now subdivided into sixty-three rural and—Fiume included—twenty-six urban municipalities, whereas in Croatia-Slavonia there are eight rural and four urban.

The population of the country at the censuses of 1881, 1891, and 1901 was:—

	1881.	1891.	1901.
Hungary proper	13,749,603	15,261,864	16,838,255
Croatia-Slavonia	1,892,499	2,201,927	2,416,304
Total	15,642,102	17,463,791	19,254,559

From 1870 to 1881 there was but little increase of population, owing to the great cholera epidemic of 1872–73, and to many epidemic diseases among children towards the end of the period. More normal conditions having prevailed from 1881 to 1891, the yearly increase rose from 0·13 per cent. to 1·09 per cent., declining in the decade 1891–1901 to 1·03.

If compared with the first general census of the country, decreed by Joseph II. in 1785, the population of the kingdom shows an increase of nearly 108 per cent. during these 116 years. Recent historical research, the results of which have been published by the Central Statistical Office, has ascertained that the country was densely peopled in the 15th century. Estimates, based on a census of the tax-paying peasantry in the years 1494 and 1495, give five millions of inhabitants, a very respectable number, which explains fully the predominant position of Hungary in the east of Europe at that epoch. The disastrous invasion of the Turks, incessant civil wars, and the devastation of the country by foreign armies and pestilence, caused a very heavy loss both of population and of prosperity. Several censuses in different counties of the country attest the enormous depopulation. In 1715 and 1720, when the land was again free from Turkish hordes and peace was restored, the population did not exceed three millions. Then immigration began to fill the deserted plains once more, and by 1785 the population had trebled itself. But as the immigrants were of very different foreign nationalities, the country became a collection of heterogeneous ethnical elements, amid which the ruling Magyar race, which had lost its best elements in the preceding wars, formed only a minority. Owing, however, to the mental gifts and political genius of the Magyars, their supremacy was never seriously disputed by any of the numerous nationalities of the country.

The density of population, according to the census of 1901, was 153·7 inhabitants to the square mile. The great Alföld and the western parts are the most densely populated, whereas the northern and eastern mountainous counties are but sparsely inhabited. But if the acreage of arable land, which yields much greater resources than the other kinds of land, and is capable of sustaining more hands, be taken as a basis of comparison, then it is found that the scanty average population of the northern and eastern mountainous counties is really denser than that of the western and middle counties. The one marked characteristic of all modern civilization—the agglomeration of population in towns—prevails in Hungary also, though there is but one really large city, Budapest, the political capital of the kingdom and the principal manufacturing town in the country. The population of the towns having in 1901 more than 40,000 inhabitants at three censuses is shown in the following table:—

Town.	1881.[1]	1891.	1901.
Budapest	360,531	505,823	732,322
Szeged	73,675	87,410	102,991
Szabadka (Maria-Theresiopel)	61,367	73,526	82,122
Debreczen	51,122	59,552	75,006
Pozsony (Pressburg)	48,006	56,048	65,867
Hódmezö-Vásárhely	52,424	55,626	60,883
Zágráb (Agram)	29,218	41,481	61,002
Kecskemét	44,887	50,600	57,812
Arad	35,556	43,682	56,260
Temesvár	33,694	43,738	53,033
Nagyvárad (Grosswardein)	31,324	70,750	50,177
Kolozsvár (Klausenburg)	30,363	37,957	49,295
Pécs (Fünfkirchen)	28,702	35,449	43,982
Miskolcz	24,319	32,288	43,096
Kassa	26,097	32,165	40,102

The number and aggregate population of all towns and boroughs in Hungary proper having in 1891 more than 10,000 inhabitants was at the censuses of 1881, 1891, and 1901:—

Census.	Towns.	Inhabitants.	Percentage of Total Population.
1881	93	2,191,878	15·94
1891	106	2,700,852	17·81
1901	122	3,525,377	21·58

Thus the relative increase of the population living in urban districts of more than 10,000 inhabitants amounted in 1901 to nearly 4 per cent. of the total population. In Croatia-Slavonia only 5·62 per cent. of the population was concentrated in such towns in 1901.

In the total population the two sexes were divided (1901) thus:—

	Males.	Females.	Females to 1000 Males.
Hungary proper (including Fiume)	8,372,839	8,465,416	1010·8
Croatia-Slavonia	1,209,333	1,206,971	998·0

The excess of females over males, which may be considered as a general feature of European civilization, is great in the western and northern counties of the kingdom, whereas in the eastern parts and in the province of Croatia-Slavonia there is a preponderance of males. Thus Hungary shows the transition from Western to Eastern distribution of sexes.

One of the prominent features of Hungary being the great complexity of the races residing in it, the census returns of 1881, 1891, and 1901, exhibiting the numerical strength of the different nationalities, are of great interest. Classifying the population according to the mother-tongue of each individual, there were, in the civil population of Hungary proper, including Fiume:—

Census.	Hungarians (*Magyars*).	Germans (*Német*).	Slovaks (*Tót*).	Rumanians (*Oláh*).	Ruthenians (*Ruthén*).	Croatians (*Horvát*).	Servians (*Szerb*).	Others.
1881	6,404,070	1,870.772	1,855,451	2,403,041	353,229	639,986		223,054
1891	7,357,936	1,990,084	1,896,665	2,589,079	379,786	194,412	495,133	259,893
1901	8,588,834	1,980,423	1,991,402	2,784,726	423,159	188,552	434,641	329,837
i.e., in percentages of the total population:								
1881	46·58	13·61	13·49	17·48	2·57	4·65		1·62
1891	48·53	13·12	12·51	17·08	2·50	1·28	3·27	1·71
1901	51·38	11·88	11 88	16·62	2·52	1·17	2 60	1·95

The results of the three censuses recorded show a decided tendency of change in favour of the dominating nationality, the Magyar. The relative importance of the other nationalities is decreasing from census to census. Thus the preponderance of the Magyars is growing. They reached an absolute majority in the decade 1891–1901. This is also shown by the data relating to the percentage of members of foreign nationalities speaking this language. This percentage was among the

Census.	Germans.	Slovaks.	Rumanians.	Ruthenians.	Croatians.	Servians.	Others.
1881	20·16	9·52	5·71	5·52	10·26		18·64
1891	25·15	12·00	6·95	7·33	16·51	11·12	21·39
1901	16·8						

No other means being used to diffuse the knowledge of the official language of the Hungarian state than elementary instruction, and

[1] For 1881 only the civil population can be given.

to some extent military service, the growth of the Hungarian-speaking elements shows the slow but steady advancement of general instruction and the effect of the internal migrations, which bring into contact with the Hungarian majority the isolated masses of foreign nationalities inhabiting the mountains in the north and east of the country. In the province of Croatia-Slavonia the language of instruction and administration being exclusively Croatian, the other races are converted to this nationality. The Hungarians form but 3·15 per cent., the Germans 5·37 per cent. of the population, according to the census of 1891.

Movement of the Population.—The following table shows the average number of marriages, births, and deaths in the kingdom per annum between 1881 and 1901:—

Year.	Marriages.	Births (Living).	Deaths.	Natural Increase (Surplus of Births).
HUNGARY PROPER.				
1881–85	142,391	626,488	467,621	158,867
1886–90	131,642	646,764	478,340	168,424
1891–95	139,064	648,300	492,753	155,547
1896	126,956	647,977	455,969	192,008
1897	131,045	651,667	453,715	197,952
1898	134,541	614,255	456,736	157,519
1899	147,912	644,577	448,756	195,821
1900	178,629	655,674	449,742	205,932
1896–1900	137,816	642,830	452,984	189,846
CROATIA-SLAVONIA.				
1881–85	21,960	87,578	61,971	25,607
1886–90	19,194	94,062	64,868	29,193
1891–95	20,893	95,009	75,433	19,576
1896	20,521	94,959	74,399	20,560
1897	20,131	96,397	75,252	21,145
1898	21,667	92,578	67,654	24,924
1899	22,914	98,695	65,528	33,117
1900	21,058	97,044	65,492	31,552
1896–1900	21,257	95,935	69,675	26,259

The marriage-rate per 1000 varied as follows:—

Division.	'81–85.	'86–90.	'91–95.	1896.	1897.	1898.	1899.	1900.	'96–1900.
Hungary proper	20·2	17·8	18·0	16·0	16·2	16·6	18·0	17·8	17·0
Croatia-Slavonia	22·4	18·0	18·8	18·0	17·4	18·6	18·4	17·6	18·2

Corresponding to the high marriage-rate, the average number of births per annum to 1000 living is also high. It was (exclusive of still-born):—

Division.	'81–85.	'86–90.	'91–95.	1896.	1897.	1898.	1899.	1900.	'96–1900.
Hungary proper	44·6	43·7	41·9	40·7	40·5	37·8	39·2	39·4	39·5
Croatia-Slavonia	44·7	44·0	42·7	41·6	41·8	39·8	42·0	40·7	41·2
Average .	44·6	43·7	42·0	40·8	40·6	38·0	39·6	39·6	39·7

The figures for 1898 were quite abnormal, and must be attributed to the complete failure of the crops in 1897 and the consequent low marriage-rate. The figures for 1900 were nearly the same as for 1899. The proportion of still-born children to 100 births was, in the fifteen years from 1881 to 1895, 1·92 per cent. There is an increase in recent years owing to more trustworthy statistics, the proportion reaching 2·20 per cent. in 1896–1900. The percentage of illegitimate births to the total number of living births was:—

1881–85.	1886–90.	1891–95.	1896.	1897.	1898.	1899.	1900.	1896–1900.
7·86	8·16	8·75	8·80	9·28	9·15	9·28	9·72	9·19

The most favourable feature in vital statistics for recent years is the constant decrease of the death-rate, shown by the following figures, for each 1000 of population per annum:—

Division.	'81–85.	'86–90.	'91–95.	1896.	1897.	1898.	1899.	1900.	'96–1900.
Hungary proper	33·3	32·3	31·8	28·6	28·1	28·0	27·3	27·0	27·8
Croatia-Slavonia	31·7	30·6	33·9	32·5	32·6	29·1	27·9	27·5	29·9
Average .	33·1	32·1	32·1	29·1	28·7	28·2	27·4	27·1	28·1

The improvement is most conspicuous in the case of Hungary proper, and is accounted for by the growth of economic prosperity as well as the advancement in sanitary administration. As a net result the natural increase per 1000 in the population was:—

Division.	'81–85.	'86–90.	'91–95.	1896.	1897.	1898.	1899.	1900.	'96–1900.
Hungary proper	11·3	11·4	10·1	12·1	12·4	9·8	11·9	12·4	11·7
Croatia-Slavonia	13·1	13·8	8·8	9·1	9·2	10·7	14·1	13·2	11·3

There is an excess of emigration over immigration. In the decades 1881–1891 and 1891–1901 for the whole kingdom it amounted to 182,000 and 185,000 persons respectively. Croatia-Slavonia alone has a surplus of immigration, owing to Hungarian emigration there. The main stream of emigration flows in the direction of the United States of America. The statistics of that country gave as the number of immigrants from Hungary:—

Yearly Average.					
1881–85.	1886–90.	1891–95.	1896.	1897.	1898.
10,111	17,201	23,827	25,879	13,791	20,920

The data collected at the German and Dutch emigration ports vary somewhat, but the averages for longer periods do not considerably differ. The emigration to America affects principally the mountainous counties of the north, and the majority of emigrants are of Slovak origin. Many of the emigrants return as well-to-do men, and the movement has caused a noteworthy increase of wages in these counties. From the south-eastern (once Transylvanian) counties there is an emigration to Rumania and the Balkan territories of 4000 to 5000 persons yearly.

Religion.—At the censuses of 1881, 1891, and 1901 the civil population in Hungary proper was divided as follows:—

Religion.	1881.	1891.	1901.
Roman Catholics . .	6,503,207	7,267,695	8,198,497
Greek Catholics . .	1,489,849	1,658,308	1,841,272
Greek Orientals . .	1,937,144	2,064,889	2,199,195
Evangelicals—			
Augsburg Confession [1]	1,107,608	1,180,714	1,258,860
Helvetian Confession [2]	2,023,360	2,212,761	2,427,232
Unitarians . . .	55,787	61,618	68,551
Jews	624,826	707,961	831,162
Others . . .	7,822	9,042	13,486

The corresponding percentages are as follows:—

Religion.	1881.	1891.	1901.
Roman Catholics	47·30	47·93	48·69
Greek Catholics	10·83	10·94	10·93
Greek Orientals	14·09	13·62	13·06
Evangelicals of Augsburg Confession	8·06	7·78	7·48
Evangelicals of Helvetian Confession	14·71	14·59	14·41
Unitarians	0·41	0·41	0·41
Jews	4·54	4·67	4·94
Others	0·06	0·06	0·08

The relative decrease in the number of those adhering to Protestant churches is caused by the low birth-rate among them, whereas the Greek Orientals suffer heavy loss by reason of the great mortality. The rapid growth in the number of Jews is owing partly to immigration, partly to economic prosperity, which latter is also manifest in the peculiarly low death-rate of the Jews (generally 18 per 1000).

Education.—Apart from the infant schools for children under six years of age (2570 in 1900), Hungary has a series of elementary schools of various kinds, numbering in 1900 (inclusive of those in Croatia-Slavonia) 18,455; Hungary proper possessed 17,048. Of this latter number 1631 were maintained by the state, 1747 by communes, and 13,357 by the different churches. The language employed in 60·6 per cent. of these schools was exclusively Hungarian, in 19·9 per cent. it was mixed. The number of teachers in the scholastic year 1899–1900, including those in the schools of Croatia-Slavonia, was 31,213; the total number of pupils was 3,255,982. The number of middle-class schools, called *gymnasia* (giving instruction in Latin and Greek), and of *real*-schools (without such courses), as well as the number of teachers and pupils, is shown by the following table for the year 1899–1900:—

Division.	Gymnasia.	Real-schools.	Teachers.	Pupils.
Hungary proper	165	32	3673	61,943
Croatia-Slavonia	19		401	6,575
Total . .	216		7074	68,518

The Hungarian language was exclusively used in 180, *i.e.*, in 91 per cent. of the 197 middle-class schools in Hungary proper. In

[1] Lutherans. [2] Helvetians, or Reformed.

9 instruction was given in the German tongue, in 5 in Rumanian. The mother-tongue of pupils was in 1891 and 1900 :—

Mother-tongue.	1891.		1900.	
	Total.	Per cent.	Total.	Per cent.
Hungarian . .	30,480	72·4	44,130	76·1
German . . .	6,213	14·7	7,066	12·1
Slovak . . .	1,577	3·7	1,853	3·2
Rumanian . .	2,704	6·4	3,482	6·0
Ruthenian . .	92	0·2	89	0·2
Croatian or Servian .	797	1·9	1,185	2·0

The increase in the number of Hungarian pupils is shown very clearly. These schools are maintained partly by the state—in 1900, 59 were so maintained in Hungary proper—and partly by ecclesiastical foundation, with or without a subsidy from the state. There are also a few *gymnasia* and *real*-schools, founded by communes and by private persons. The total expenditure on middle-class schools in 1899–1900 was 16,386,000 crowns (a crown=10d.). There are two universities in Hungary proper, one at Budapest and one at Kolozsvár; in Croatia-Slavonia there is a university at Zágráb. The latter has faculties of theology, law, and philosophy; the two former have in addition a faculty of medicine. The number of professors (ordinary and extraordinary), lecturers, and undergraduates in 1899–1900 is shown by the following table :—

University.	Professors.	Lecturers.	Undergraduates.
Budapest . .	119	182	5546
Kolozsvár . .	51	44	1210
Zágráb . . .	35	31	770

There are 10 high schools of law, called academies, with, in 1899–1900, 80 professors, 40 lecturers, and 1569 pupils. The number of high theological colleges in Hungary is 49—29 Roman Catholic, 5 Greek Catholic, 4 Greek Oriental, 10 Protestant, and 1 Jewish; in 1899–1900 there were 1599 pupils. The polytechnicum at Budapest, with 34 professors and 74 lecturers, had 1772 pupils in that year; the number of art-schools was 45, with 337 teachers and 5139 pupils. The percentage of illiterates (*analphabeta*), which was 59·7 in 1881, had by 1891 decreased to 57·8, and in 1901 to 50·4. The percentage for Hungary proper only is more favourable (in 1891, 55·5, and in 1901, 48·6 per cent.). Omitting children under six years of age, 55 per cent. of the population could read and write. In Croatia-Slavonia only 33·4 per cent. could do so. The average number of periodicals in 1881–85 was 672; in 1900 there were 1396. Of this latter number 938 appeared in Hungarian, and 209 were political papers.

Pauperism.—There is no government system of poor relief in Hungary. Private beneficence and ecclesiastical charity assist the poor, and if these sources fail the commune has to supplement them. Thus the total amount expended on the poor cannot be ascertained. But the XXI. Art. of 1898 assures to the sick gratuitous medical help and total maintenance to deserted children under seven years of age, and for these purposes a special tax, which cannot exceed 3 per cent. of the direct taxes, is levied.

Crime.—The Penal Code of 1878 divides criminal offences into two classes—the more and the less serious; there are also misdemeanours punishable by fines and imprisonment. The total number of convicted persons in each of these three categories was, in Hungary proper :—

Year.	Criminal Offences.		Misdemeanours.
	More Serious.	Less Serious.	
1894	10,198	75,846	299,501
1898	11,169	84,360	368,796
1900	4,035	64,641	335,231

Crimes of the gravest nature, those against life and property, are diminishing, but political misdemeanours increase rapidly, owing to new laws creating new offences. The only important change of a judicial character since 1871 has been the decentralization of the "Királyi itélötáblák" (1891). Their number now amounts, in Hungary proper, to eleven. For most cases they are the highest courts of appeal, but there is a still higher tribunal for cases of the first importance. The new Code of Procedure (XXXIII. Art. of 1896) and the Law on Juries (XXXIII. Art. of 1897) have been in force since 1st January 1900. These laws extended the jurisdiction of juries to the gravest crimes and introduced great reforms, conforming to modern principles of criminal procedure.

Constitution and Government.—There has been only one reform in the composition of parliament since 1867, namely, that regarding the House of Lords (*Förendiház*). Art. VII. of the year 1885 ordered that this House should consist of—(1) all the archdukes who have attained their majority (eighteen years); (2) hereditary peers (that is, princes, counts, and barons) above twenty-four years of age, provided that the title was in the family before 1885, and that the peer is personally charged with a land-tax of 3000 fl. (£250); (3) Hungarian peers obtaining this right by order of his Majesty; (4) other citizens named by the king, up to a maximum number of fifty; (5) members by virtue of office, *i.e.*, thirty-two archbishops and other dignitaries of the Roman Catholic Church, ten dignitaries of the Greek Church, thirteen representatives of the three Protestant confessions, a few state dignitaries, and five high judges; (6) three delegates of the Croatian-Slavonian Parliament. The total number of members in 1900 was 398. The number of electors to the House of Commons (*Képvislöház*) in 1879 was 824,602; in 1887, 847,216; in 1900, 989,009, or 2395 electors for one deputy. The percentage of electors to the total population was 6 per cent. in 1879 and 5·95 per cent. in 1900. A thorough reform of the local administration has been prepared by the Government.

Finance.—The total annual revenue and expenditure of the state—deducting merely transitory items of credit operations and conversions—were, in millions sterling :—

Year.	Revenue.	Expenditure.	Surplus.
1891–95	42·1	39·4	2·7
1896	43·2	43·0	0·2
1897	46·4	45·6	0·7
1898	43·8	43·7	0·2
1899	42·9	42·8	0·1
1900	45·4	45·2	0·2

The total debt at the end of each of the following years was, in millions sterling :—

1891.	1895.	1898.	1899.	1900.
171·9	181·3	184·3	184·6	192·8

The ordinary revenue of the state is derived chiefly from direct and indirect taxation, including monopolies. In 1900 direct taxes amounted to £9,410,000, indirect to £17,048,000. Among the indirect taxes, that on alcoholic drinks yielded £5,201,000, the monopoly of tobacco £4,767,000 (of which £2,565,000 is net revenue). State forests gave £795,000. The growth in the revenue derived from state railways is shown by the following table (amounts in millions sterling) :—

Year.	Total Receipts.	Expenditure.	Net Revenue.
1881	1·5	1·0	0·5
1890	3·5	2·1	1·4
1898	8·4	5·6	2·8
1899	8·5	5·6	2·9
1900	9·1	6·7	2·4

Already the net revenue corresponds to nearly 4 per cent. of the capital invested, and the prospects of increase may be regarded as very favourable.

Production and Industry.—Though the mineral resources of the country are very great, mining and smelting works only employed 70,476 persons in 1900. This, however, shows an increase compared with the average of 1881–85, which was 47,817, and with that of 1886–90, which was 49,178 persons, whereas the average of 1891–95 was 60,456. The principal products of mining are returned as follows :—

Mineral.	Yearly Average Quantities in Cwts.[1]				
	1881–85.	1886–90.	1891–95.	1896–99.	1900.
Gold[2] . .	32	38	42	61	64
Silver . .	325	333	390	438	397
Pig iron .	3,650,118	4,604,073	6,350,837	8,900,560	8,967,673
Coal . .	45,095,866	54,323,382	77,597,963	107,455,631	127,898,942

The growth in the production of iron and coal is shown more clearly if the quantities raised in the first and last years of the period are compared. The following are, then, the figures in English tons (1 metric ton=1000 kg.=0·984 Eng. ton) :—

Mineral.	1881.	1899.	1900.
Pig iron . .	161,376	478,941	462,952
Coal . .	1,929,774	6,098,412	6,602,913

Thus the production of iron, as well as that of coal, was trebled in nineteen years. There are excellent iron ores in the northern and south-eastern counties, but the quality of coal raised

[1] Calculated in this proportion: 1 metric centner equal to 100 kilograms = 220·5 lb av.

[2] Each kilogram having a value of £136·56; a metric centner is worth £13,656.

is rather unsatisfactory, the greater part of it being only brown coal, which cannot be transformed into coke. The number of blast-furnaces, which was 106 in 1881, only amounted to 68 in 1900.

Agriculture.—The pre-eminence of agriculture as the chief economic resource of Hungary is shown by the high percentage which the agricultural class forms of the total population. In 1891 this was 75·1 per cent. in Hungary proper and 85·2 per cent. in Croatia-Slavonia. The agricultural inquiry of 1895 showed an increase in the area of arable land, but a diminution in the area covered by vineyards, which had suffered greatly from the devastations of the phylloxera. The main varieties of land are distributed as follows:—

By Area in Acres.

Country.	Arable Land.	Gardens.	Meadows.	Vineyards.	Pastures.	Forests.	Marshes.
Hungary proper .	29,714,382	928,053	7,075,888	482,801	9,042,267	18,464,396	199,685
Croatia-Slavonia .	3,370,540	136,354	1,099,451	65,475	1,465,930	3,734,094	7,921

By Percentage of the Total Area.

Hungary proper .	42·81	1·34	10·19	0 69	13·03	26 60	0·28
Croatia-Slavonia .	32 26	1·31	10 52	0·63	14·03	35·74	0·08

The remainder, such as barren territory, devastated vineyards, water, and area of buildings, amounts to 5·1 per cent. of the total. The progress of agriculture is shown by the increase of arable land, the diminution of bare fallow land, and the growth of the average production, which may be regarded as a proof of increasing intensity, improvements, and technical progress. The chief agricultural products of Hungary are wheat, rye, barley, oats, and maize, and the annual crops of these for a period of nineteen years are shown in the following tables:—

Area in Acres in Hungary Proper.

Cereal.	Average per Annum.			1896.	1898.	1899.	1900.
	1881-85.	1886-90.	1891-95.				
Wheat .	6,483,876	7,014,891	7,551,584	7,751,566	6,866,390	7,798,000	8,142,303
Rye .	2,475,301	2,727,078	2,510,093	2,725,166	2,468,283	2,596,500	2,546,738
Barley .	2,420,393	2,491,422	2,407,469	2,375,105	2,336,353	2,508,200	2,485,117
Oats .	2,460,080	2,546,582	2,339,297	2,434,805	2,215,672	2,380,500	2,324,992
Maize .	4,567,186	4,681,376	5,222,538	5,098,213	4,909,809	5,257,600	5,469,050

Produce in Millions of Bushels.

Cereal.	Average per Annum.			1896.	1898.	1899.	1900.
	1881–85.	1886–90.	1891–95.				
Wheat	99·8	121·3	144·9	113 6	96·0	136·4	137·3
Rye .	41·8	42·1	46·5	33·6	30·0	44·0	39·2
Barley	46·2	43·7	53·6	36·6	34·4	52·7	49·7
Oats .	53·9	52·3	64·9	29·7	61·6	64·8	63·6
Maize .	92·4	86·4	118·0	91·6	89 1	108·0	121·7

In Croatia-Slavonia no crop statistics were compiled before 1885. Recent returns for maize and wheat show an increase both in the area cultivated and quantity yielded. The former is the principal product of this province. The number of live stock in Hungary proper in two different years is shown in the following table:—

Animal.	1884.	1895.
Horses . .	1,749,302	1,972,930
Cattle . .	4,879,334	5,829,483
Sheep . .	10,594,867	7,526,783
Pigs . .	4,803,777	6,447,134

In Croatia-Slavonia the live stock was numbered in 1895 at: horses, 309,098; cattle, 908,774; sheep, 595,898; pigs, 882,957. But the improved quality of the live stock is more worthy of notice than the growth in numbers. And the increasing area devoted to the cultivation of clover and nutritious grasses, the improvement in the breed of horses and cattle, procured by administrative measures and fiscal protection, the prizes and other encouragements offered, are all features which ensure a still further development in this important branch of production.

Industry.—The number of persons employed in the various manufacturing industries in 1891 was 831,172 in Hungary proper and 81,838 in Croatia-Slavonia. The total number of those dependent on manufacturing industries formed 13 per cent. of the population in Hungary proper and only 8·3 per cent. in Croatia-Slavonia. In 1891 there were in Hungary proper 1134 establishments employing more than twenty hands; in 1898 the number was 1626. Thus in seven years there was an increase of 43·4 per cent. The number of factories with more than 1000 workmen was 11 in 1891 and 27 in 1898. The industry in the highest state of development is that connected with mills. The number of steam-mills was 147 (about) in 1863, 492 in 1873, 910 in 1885, and 1723 in 1895, when the total horse-power of the steam-engines was 68,929. There are 2,952,000 English tons of wheat-flour produced annually. The number of breweries decreased down to 1890, when there were 95 in the whole kingdom. But production on a large scale survived the competition of the Austrian breweries, and the average annual production of beer increased from 11,019,280 gallons in the decade 1881–90 to 34,820,936 gallons in the years 1894–98. There were 99 breweries in 1900, and they produced 31,862,900 gallons of beer. The same tendency to production on a large scale prevails in the alcohol and sugar industries. But whereas in the former production is rather on the decline owing to the heavy taxes on alcohol, the sugar industry is advancing with rapid strides. The more equal rate of taxation, which made possible the competition of Hungarian with Austrian factories, though the latter had better raw material and more capital, increased the production in a few years. The growth is shown by the fact that the average annual weight of beet used increased sixfold from 1880–88 to 1896–98; in the last of these years 3,996,959 cwts. of sugar were produced, 20 large factories sharing in the yield. In the season of 1898–99 the produce increased to 4,857,897 cwts., in 1899–1900 to 4,936,419 cwts. The tobacco industry is a monopoly, and the factories are under the state. The increase in the annual production of cigars, cigarettes, snuff, and other kinds of tobacco ready for consumption is shown by the following table:—

Year .	1881–85.	1886–90.	1891–95.	1896–99.	1900.
Cwt. .	277,158	312,380	389,472	432,594	411,490

Having renewed with Austria treaties of commerce, which now constitute a customs union, Hungary cannot protect industry by duties. To encourage the investment of capital in industrial establishments, several Acts exempt from taxation new branches of manufactures and those factories provided with the best modern machinery. This has led to several factories being established with the aid of national and foreign—including English—capital.

Commerce.—The foreign trade of Hungary, including Croatia-Slavonia, is shown by the following table, in millions sterling:—

Year.	Imports.	Exports.
1886–90	37·3	37·5
1891–95	43·7	44·1
1896	45·6	45·3
1897	46·1	45·0
1898	49·7	46·0
1899	49·7	50·0
1900	46·3	55·3

Of the merchandise entering[1] the country, 75–80 per cent. comes from Austria, and exports go to the same country to the extent of 75 per cent. (in 1900 only 71·6 per cent.). Next comes Germany with about 10 per cent. of the value of total exports and 5 per cent. of that of imports. The neighbouring Balkan states—Rumania and Servia—follow, and the United Kingdom receives somewhat more than 2 per cent. of the exports, while supplying about 1·5 per cent. of the imports. The value of the principal articles of import and export is shown in the following tables, in thousands of pounds sterling:—

Imports.	1897.	1898.	1899.	1900.
Cotton goods . . .	5882	5941	6787	5933
Woollen manufactures .	3797	4200	4520	3730
Apparel, haberdashery, and linen . .	2398	2564	2780	2837
Silk manufactures . .	1832	2186	2437	2024
Leather, raw . . .	1361	1253	1277	1276
Leather manufactures .	1199	1274	1205	1048
Wine in barrels . .	1265	1236	...	1005

Exports.	1897.	1898.	1899.	1900.
Flour	6994	6906	6123	6526
Wheat	3081	2635	2925	3527
Beef	3176	3051	3589	3848
Barley	2602	2144	2544	2363
Pigs	1390	1590	2072	2478
Wine in barrels . .	1419	1265	1103	1347
Horses	1295	1182	1279	1192
Maize	1340	1166	1396	1322

[1] Merchandise passing the boundaries is subject to declaration; the respective values are stated by a special commission of experts residing in Budapest.

The above figures plainly show the prevailing agricultural character of the country, grain, flour, and animals, including dead meat, being the chief articles of export, whereas textile manufactures supply by far the most important item in the imports. But coal, of the value of nearly twenty millions of crowns, tobacco, rice, iron, and especially iron goods, are also imported in large quantities of great value.

Navigation.—The shipping of Fiume, the chief port of Hungary, shows great progress. The following table gives statistics of the vessels with cargoes which entered and cleared:—

Year.	Entered.		Cleared.	
	Vessels.	Tonnage.	Vessels.	Tonnage.
1881–85	2,505	401,714	3010	523,623
1891–95	5,091	721,456	4604	772,433
1896	6,336	912,338	6120	963,117
1897	9,620	1,151,194	9397	1,193,859
1898	9,893	1,283,425	9767	1,289,594
1899	10,006	1,291,531	9930	1,425,533
1900	10,739	1,681,151	10,733	1,684,329

At all ports in 1900 there entered 19,223 vessels of 2,223,302 tons; cleared, 19,218 vessels of 2,226,733 tons. The tonnage of British steamers amounted to somewhat more than 11 per cent. of the total tonnage of steamers entered and cleared.

Railways.—The total length in English miles of the railways open is shown in the following table:—

1875.	1885.	1895.	1896.	1897.	1898.	1899.	1900.
3985	5601	8644	9236	9778	10,161	10,513	10,624

The principal lines, extending to a length of 4756 miles, are owned by the Hungarian state, and important sections of private railway lines are also administered by the state, only 1835 miles being possessed and controlled in 1900 by private railway companies. The total capital invested amounted at the end of 1900 to £136,078,000, the state's share of which was no less than £91,106,000. The number of passengers conveyed yearly is shown in the following table:—

1886–90.	1891–95.	1896.	1897.	1898.	1899.	1900.
17,928,442	45,061,000	57,452,000	56,982,000	60,312,000	61,581,000	64,412,000

The receipts from passengers and from goods traffic amounted to—

Year.	Passengers.	Goods Traffic.	Total (including miscellaneous).
1880	£1,000,000	£3,300,000	£4,300,000
1890	1,600,000	5,400,000	7,100,000
1898	2,600,000	7,400,000	10,600,000
1899	2,700,000	7,600,000	10,800,000
1900	2,799,000	8,216,000	11,471,000

Thus the receipts from passengers nearly trebled during two decades, and those from the goods traffic increased 150 per cent., though the tariffs were much reduced. (See *Finance.*)

Post and Telegraphs.—The number of post-offices at the end of 1900 was 4923. The total number of letters, post-cards, newspapers and other papers delivered was (in millions)—

Average of	Millions.	Year.	Millions.
1886–90	230·4	1896	350·9
		1897	372·7
1891–95	284·5	1898	400·6
		1899	440·8
1896–1900	414·8	1900	508·7

The number of letters and cards only in 1900 was 260 millions; of newspapers only, 116 millions.

The total length of telegraph lines was, in 1900, 22,824 kilometres; of wires, 114,831 kilometres. The number of messages forwarded amounted in the same year to 7,573,200.

Banks.—The total number of joint-stock banks and others in Hungary proper is shown by the following table:—

Year.	1868.	1878.	1888.	1895.	1898.	1899.	1900.
Banks	156	663	1130	1841	2329	2363	2623

In 1900 Croatia-Slavonia had 253 banks. The value of deposits (savings included) in the whole kingdom at the end of 1900 was 2,088,500,000 crowns (24 crowns = £1). In the postal savings department 32,674,000 crowns were deposited.

AUTHORITIES.—The various statistical reports of the Central Statistical Office include all the material available. A summary of them is annually published under the title, *Magyar Statisztikai Évkönyv* (*Statistical Year-book of Hungary*).—MATLEKOVICS. *Magyarország Kozgazdasága és Közmüvelodés Ilapota ezeréves fenállásakor.* Budapest, 1897–98 (9 volumes, German edition 2 vols).—The Hungarian part of the *Az Osztrák-magyar monarchia írásban és képben.*—CHÉLARD. *La Hongrie millénaire.* Paris, 1896. (Z. R.)

RECENT HISTORY.[1]

The occupation in 1878 of Bosnia and Herzegovina by Austria-Hungary in accordance with article 23 of the Treaty of Berlin was from the first unfavourably viewed in the Hungarian kingdom. There were various reasons for this attitude on the part of the Hungarians; they were jealous of Austrian interference south of their own territory, partly out of fear of the encroachments of Pan-Germanism, and partly because of the friendly feelings they entertained for Turkey, which had welcomed their refugees in the revolution year of 1848. Moreover, the Hungarian finances, which at last, after many years of careful management, seemed to be established on a firm basis, would not, it was apprehended, stand the prolonged strain of a military intervention with all the concomitant hazards. In October 1878 the minister of finance, Koloman Szell (b. 1843), resigned, and the whole cabinet with him, but it was almost immediately modified and reconstituted under Tisza (*q.v.*). At the head of the strong Liberal party he succeeded in allaying the popular indignation, which had found vent in revolutionary meetings, and even excesses, and in persuading the chamber to vote the supplies and continue the military establishment for a further period of ten years. In return for these sacrifices Austria allowed Hungary a freer hand in her policy of Magyarization.

During the next few years various reforms were carried through; the municipal administration was reorganized, instruction in the Hungarian language was made obligatory in the popular and intermediate schools, and the reconstitution of the House of Magnates, which had long been a burning question, passed into law in 1885. In the lower house the period for which deputies were elected was extended from three to five years. The general state of unrest culminated in 1883 in anti-Jewish riots; but this was only a passing storm, and the national exhibition held in Budapest in 1885 concentrated the public mind upon the economic possibilities of the country and the potentialities of the capital city. In the ensuing year Tisza enunciated in parliament the Austro-Hungarian Balkan policy, declaring for the Treaty of Berlin and the independence of Bulgaria. His utterances, though welcomed in the sister state and in Europe at large as a weighty and valuable pronouncement and an earnest of peace, gave umbrage in Hungary itself. The increase in the military budget necessitated by the general state of disquietude in Europe, and a new Army Bill, providing for the reconstitution of the Landsturm, introduced in 1889, added to the public indignation, and rioting in Pesth and other large centres was only suppressed by military intervention. Tisza, however, firmly stood his ground, and again, as in 1878, asked the house to vote the Army Bill (*Wehrgesetz*), providing for the continuance of the military establishment at the same strength for a further period of ten years. Certain clauses of the Bill, rather than its general policy, aroused opposition, notably that requiring volunteers of one year's service to pass their examination in German. This clause was bitterly assailed as a retrograde movement and a menace to the Magyarization of the country. Tisza eventually carried his points, but he had to resort to all the devices of constitutional procedure open to him to compass his ends. Thwarted on the Army Bill, the Radical wing

[1] See also AUSTRIA-HUNGARY, *History*.

next turned its attention to the domicile law (*Heimathsgesetz*), demanding its amendment so as to permit of the return of Kossuth (*q.v.*), who by voluntary self-banishment for more than ten years had *ipso facto* ceased to be a Hungarian citizen. The cabinet, with the exception of Tisza, who favoured this step, declined to identify itself with the motion, and Tisza accordingly resigned (1890); yet the ex-minister, after taking this step, retained his seat in parliament, and was still regarded as the head of the party. The fifteen years (1875–90) during which Tisza held undisputed sway mark the creation of modern Hungary, and as long as his counsels were available the nation looked to him to direct its policy.

Count Julius Szapáry (b. 1832) undertook the presidency of a new ministry, and expressly declared that the Government would adhere to the lines of the policy pursued by Tisza, who, in his turn, loyally promised his support. One of the first acts of the new minister was to revive his predecessor's measure of administrative reform. This, the so-called *Verstaatlichung der Verwaltung*, was in effect the withdrawing from the countries of their elective and autonomous administration, and the substitution of a centralized or state administration. Introduced in 1892, the Bill, owing to the sustained obstruction of the Opposition, had to be abandoned. A short measure, accepting the principle of state organization, was substituted and carried, but the main measure remained in abeyance, the old provincial autonomy persisting in full force.

In this year (1892) new currency reforms were introduced, and a Bill establishing a gold standard became law. With the removal of the Calvinist Tisza, whom they regarded as their most dangerous enemy, the militant clerical element considered the opportunity favourable for entering an energetic protest against the measures of ecclesiastical reform which formed the Government programme. The Civil Marriage Bill, which, though a separate measure, formed part of this grand scheme of reform, was specially singled out for attack, and the remonstrances of the clergy culminated in a conference of bishops in the autumn, at which the pope's support of the clerical opposition was made known. Another *quæstio vexata* was that of the baptism of the children of mixed marriages. The law of 1868 provided that of the issue of such marriages the males should be brought up in the religion of the father and the females in that of the mother, and imposed upon the clergy baptizing a child not of their confession the duty of communicating the fact to the clergy of the other confession. This law, it was notorious, had for a long time past been evaded by the Roman Catholic clergy, who had been in the habit of claiming and baptizing all children of mixed marriages. The antagonism between the Government and the Catholic clergy now became so intense that, on the return of the old Liberal majority to power by the elections of the autumn of 1892, Alexander Wekerle (b. 1844), who had succeeded Szapáry as premier, at once laid before the Diet a sweeping scheme of reform, consisting of Bills for the introduction of civil marriage, civil registration, and the education of children of mixed marriages. The House of Magnates at first rejected the Civil Marriage Bill, but eventually all these Bills composing the scheme of ecclesiastical-political reform were carried through the two houses together.

In 1892 the Rumanian party in Transylvania had begun a serious agitation against the inequality with which they alleged they were treated, and they attempted in vain to go behind the Government and obtain personal redress from the king. At a Pan-Rumanian congress at Hermannstad in July 1893, a memorandum of their grievances was formulated, and Wekerle seized the opportunity to prosecute the leaders for treason. Twenty of them were sentenced (May 1894) to imprisonment; but the king was by no means satisfied either with Wekerle's action in this matter or with his encouragement of the popular demonstrations after Kossuth's death in March 1894, and in December 1894 Wekerle's ministry was dismissed. The year 1894 was remarkable for the jubilee of the literary career of Maurus Jókai (*q.v.*), and the celebrations held throughout the length and breadth of the land showed the strength and depth of the Magyar feeling of nationality.

In January 1895 Baron Desider Bánffy (b. 1843) formed a new Government, and began by completing two of Wekerle's measures, that sanctioning the Jewish religion and that establishing freedom of worship. In this he was successful in spite of the bitter opposition of the clericals backed by Mgr. Agliardi, the papal nuncio. The interference of the latter led to a serious disagreement between the premier and Count Kalnoky (the Federal minister for foreign affairs, *q.v.*), with the result that Kalnoky was forced into resignation. Bánffy's first great task was the renewal of the *Ausgleich* (see AUSTRIA-HUNGARY), and to this he addressed himself with vigour. It was owing to his conciliatory policy that the Austrian monarchy was won over to a complete recognition of the equality of Hungary; Hungarian state officials were appointed to the king's court on the monarch being resident in Hungary, and ministers of the imperial house became known by the title "imperial and royal" (*kaiserlich-königlich*). The millennium exhibition held at Budapest in the summer of 1896 was a complete success, being especially favoured by the royal house, which in its turn was loyally received by the Hungarian people and houses of legislature. In view of the enhanced prosperity of the country as evidenced by the exhibition, Austria now demanded that the Hungarian subvention to the common expenses (quota) should be considerably increased; the current saying in Austria being that "Hungary enjoys 70 per cent. of the power in the dual monarchy for 30 per cent. of the cost." But the proposal to raise the quota from 31½ per cent. to 34 per cent. met with much opposition, the Government being unwilling to make even this concession, and at the same time Badeni's endeavours to gain over the Czechs to the *Ausgleich* drove the Germans in the Austrian parliament to opposition, and the further discussion of the measure was accordingly postponed and parliament dissolved.

The new elections resulted in a magnificent triumph for the Government, but as it was impossible, owing to the shortness of the session, to renew the attempt to pass the *Ausgleich*, a provisional arrangement for a year was proposed. But the obstruction of the Germans in the Austrian parliament still continued and prevented the passing of the *Ausgleichs provisorium*, and the whole of the year 1897 was practically taken up with the discussion of this measure and that of the broad lines of the economic policy of the dual monarchy. It was not until January 1898 that the *Ausgleich* with Austria was, at the instance of the Hungarian Government and with the consent of the parliament, prolonged until the following May. The discussions in parliament gave Bánffy an opportunity of declaring his unalterable allegiance to the dual monarchy, and of enunciating the policy of his Government, which was not merely that of preserving the *status quo* with Austria, but of binding that country by still closer ties to the Hungarian kingdom. The emperor-king, grateful for these evidences of loyalty, gave his assent to a new law for the Magyarization of names of places in Transylvania. This gave rise to a vehement protest on the part of the various nationalities in those districts, especially the Saxon element, whose representatives, as a demonstration against this measure, withdrew from the ranks of the Liberal majority. Among other disquieting symptoms of trouble during the summer of

1898 was the spread of agrarian socialism in the country, which was intensified by a bill regulating the relations between landowners and their labourers. Meanwhile the discussion of the *Ausgleich* roused public feeling to a fever pitch. The assassination of the empress-queen in September 1898 had for the moment a sobering effect, and the proposal of the emperor-king to give the site in Ofen, occupied by the Hentzi monument, which had ever been an eyesore to patriotic Hungarians, for the monument to her memory to be erected by public subscription was enthusiastically received. But an order for the re-erection of the Hentzi statue in the barrack-yard of the cadet school gave rise to fresh obstruction, and led to stormy scenes in the chamber; and the mutual recriminations of parliamentarians resulted in a crop of duels, among which that between Bánffy and Horansky, the premier's bitterest assailant, was conspicuous. The new year (1899) brought no cessation of the obstruction, and it soon became evident that nothing less than the resignation of Bánffy would satisfy the obstructionist group, whose tactics threatened to be subversive of constitutional government in Hungary. In February the crisis culminated in the resignation of the Bánffy ministry, Koloman Szell being entrusted with the formation of a new cabinet.

Thus closed for Hungary a most momentous period in her modern political history. With the new premier's accession to power the parliamentary deadlock came to an end, and a compromise having been effected with the three opposite groups, the *Ausgleich*, embodied in a series of bills, was carried through both houses of legislature in July. Between then and the end of 1901, Hungarian politics was only disturbed by the periodical outbursts of anti-Magyar feeling in Austria, where the tension between the two countries as the outcome of commercial jealousy made itself acutely felt at times. Thus, with regard to the Bosnian railway question, the Hungarians, who had a monopoly of railway connexion with Bosnia, were accused of placing impediments in the way of the construction of the short lines intended to connect the Bosnian state railway with Croatia and Austria on the one side, and with the Dalmatian coast at Spalato on the other. Undoubtedly the feelings aroused in Austria were natural enough. As it was the ambition of the Magyars to make of their country a model industrial state, the Government left no stone unturned in its endeavour to attain this end. Austrian competition was successfully combated by a system of bounties to Hungarian manufactures which, while affording the necessary protection, ran counter to the spirit, if not to the letter, of the customs union. The result was that Austrian manufacturers and traders were attracted in large numbers to Hungary, while Austrian industries were dealt a correspondingly heavy blow. But in the distracted state of parliamentary politics in Austria (*q.v.*), no remedy for this was discernible.

The political situation between the years 1870 and 1902 was largely dominated by the conflict between the Catholic and Protestant interests. Beginning in 1867 with Deák, it found its culminating point in the ultra-Calvinist, Koloman Tisza, while in the last years of the century an extraordinary development took place. Tisza, with the Government party, endeavoured to realize Protestant aims, whilst an independent Protestant party became a thorn in the side of the Government. At the beginning of the 'nineties a Catholic reaction set in with Szapáry, but he, after a short term of office, was forced by Desider Szilágyi (*q.v.*), the relentless champion of Calvinism, to resign. His successor, Wekerle, was dismissed largely as a result of Catholic influence in Vienna. In Bánffy, again, is found a Protestant of extreme Calvinistic leanings, who carried on his high-handed policy by uniting the forces of Judaism and Protestantism, and whose questionable methods at the elections of 1897 left a blot upon the escutcheon of Hungarian statesmanship. After his fall, Szell, a Catholic, undertook the formation of a ministry, and this party, victorious in Hungary, occupied in 1902 the position formerly filled by the Protestant party.

Hungarian Literature.

The number of Magyar writers has since 1880 increased to an extent hardly expected by the reading public in Hungary itself. In 1830 there were only 10 Magyar periodical publications; in 1880 we find 368; in 1885 their number rose to 494; in 1890 to 636; and at the beginning of 1895 no less than 806 periodical publications, written in the Hungarian language, appeared in Hungary. Since that time (1895) the number of periodical as well as of non-periodical literary works has been constantly rising, although, as in all countries with a literature of rather recent origin, the periodical publications are, in proportion to the whole of the output, far more numerous than the non-periodical.[1]

This remarkable increase in the quantity of literary work was, on the whole, accompanied by a fair advance in literary quality. It cannot be said that a new literary generation had arisen, since many of the shining lights of the 'sixties and 'seventies still remained in the field in 1901. In lyrical poetry, among the poets who first came to the fore in the 'sixties several were still active between 1880 and 1901, such as Joseph Komócsy (d. 1894), whose *Szerelem Könyve* ("Book of Love") has become a popular classic; Victor Dalmady, who published in the 'nineties his *Hazafias Költemények* (Patriotic Poems); and Ladislas Arany, son of the great John. Among the prominent lyrists whose works, although partly published before 1880, belong largely to the later period, the following deserve special mention:—The poetry of Emil Ábrányi (born 1850) is filled with the ideas and ideals of Victor Hugo. Ábrányi excels also as a translator, more particularly of Byron. Julius Reviczky (1855–1899) also inclined to the Occidental rather than to the specifically Magyar type of poets; his lyrics are highly finished, aristocratic, and pessimistic (*Pán halála*, "The Death of Pan"). Count Géza Zichy (born 1849) published his lyrical poems in 1892. Joseph Kiss (born 1843) is especially felicitous in ballads taken from village and Jewish life, and in love-songs; Alexander Endrődi (born 1850), one of the most gifted modern lyrical poets of Hungary, has the charm of tenderness and delicacy together with that of a peculiar and original style, his *Kurucz nóták* being so far his most successful attempt at romantic lyrics. Louis Bartók (born 1851) is a remarkable satirist and epigrammatist (*Kárpáti emlékek*). Ödön Jakab (born 1850) leans towards the poetic manner of Tompa, with perhaps a greater power of expression than the author of the *Virágregék* ("Flower-fables"); Jakab wrote *Hangok az ifjuságból* ("Sounds of Youth"), *Nyár* ("Summer"), both collections of lyrical poems. Louis Pósa (born 1850) has made a sphere of his own in his charming poems for and about children, *Édes anyám* ("My dear Mother"). In Andor Kozma (born 1860), author of *A tegnap és a ma* ("Yesterday and To-day," 1889), *Versek* (Poems, 1893), &c., there is undoubted power of genuine satire and deep humour. Michael Szabolcska (born 1864), author of *Hangulatok* ("Moods," 1894), showed great promise; Julius Vargha (born 1853) cultivates the *népies* or folk-poetry as represented by Hungary's two greatest poets, Petőfi and Arany; Vargha has also published excellent translations of Schiller and Goethe. Perhaps scarcely less remarkable are the modern Magyar lyrists, such as, of the older set, John Bulla (born 1843), J. D.

[1] This will appear even more striking by a consideration of the number of periodical publications published in Hungary in languages other than Magyar. Thus, while of German periodicals appearing in Hungary there were in 1871 only 85, they increased in 1880 to 114, in 1885 to 141; and they were, at the beginning of 1895, still 128, in spite of the constant spread of that process of Magyarization which has, since 1880, considerably changed the linguistic habits of the people of Hungary.

Temérdek, Gustavus Csengey (born 1842), Paul Koroda (born 1854), E. Julius Kovács (born 1839, *Poems*, 1892), Ladislas Inczédi, Julius Nógrádi Pap, Julius Szávay (born 1860), John Dengi (born 1853); among the juniors, Anton Radó (also an excellent translator), Louis Palágyi (*Magányos úton*, "On Lonely Way," &c.), Géza Gárdonyi (born 1863, *Aprilis*, 1894), Zoltán Pap, Eugen Heltai (*Ignotus*), Julius Rudnyánszky (born 1860, *Szerelem*, "Love"; *Nyár*, "Summer"), Árpád Zemplényi, Julius Szentessy, Emil Makai (born 1870), Cornelius Gáspár, Julius Varsányi (born 1863, *Mulandóság*, "The Unstableness of Things"), Alexander Luby (*Vergődés*, "Striving"), Eugen V. Szászvárosi, Endre Szabó (born 1849), political satirist. In the most recent lyrics of Hungary there is a growing tendency to socialistic poetry, to the "poetry of misery" (*A nyomor költészete*). In epic poetry Josef Kiss's *Jehova* is the most popular work. Amongst rhymed novels—novels in verse form—the best is the *Délibábok hőse* ("The Hero of Mirages"), in which Ladislas Arany tells, in brilliantly humorous and captivating fashion, the story of a young Magyar nobleman who, at first full of great ideals and aspirations, finally ends as a commonplace country squire.

Among Hungarian novels we may distinguish four dominant *genres* or tendencies. The first is represented almost exclusively by Maurus Jókai, who has gratified his countless admirers, both in Hungary and abroad, with numerous new manifestations of his inexhaustible *verve* and genius. The national festivities instituted in Jókai's honour in 1894, culminating in his being made, in 1897, a member of the Hungarian House of Magnates (the House of Lords in Hungary), publicly recognized the obligation under which Jókai's works had laid the Magyar nation. Amongst Jókai's later novels are: *A kik kétszer halnak meg* ("Those who die Twice"); *Szeretve mind a vérpadig* ("Loving to the very Scaffold"); *A lőcsei fehér asszony* ("The White Lady of Locse"); *A Kis Királyok* ("The Little Kings"); *A tengerszemü hölgy* ("The Lady with the Sea-eyes"): *Fráter György* ("Frater George"); *De kár megvénulni* ("What a pity to grow old"); *Életemből* (Memoirs); poems, dramas, &c. To the school so perfectly represented by Jókai belong Árpád Kupa (*A napszámosok*, "The Labourers"; *Képzelt királyok*, "Imaginary Kings"); Robert Tábori (*Nagy játék*, "Great Game"; *A negyvenéves férfiu*, "The Man at Forty"); and Julius Werner (*Kendi Imre házassága*, "The Wedding of Emericus Kendi"; *Olga; Megvirrad még valaha*, "Dawn will come in the End"). The second class of Hungarian modern novelists is led by the well-known Koloman Mikszáth, a poet endowed with originality, a charming *naïveté*, and a freshness of observation from life. A close observer of the multifarious low life of Hungary, Mikszáth has, in his short stories, given a delightful yet instructive picture of all the minor varied phases of the peasant life of the Slavs, the *Palócok*, the Saxons, the town artisan. Amongst his numerous works may be mentioned *A jó palóczok* ("The Good Palóczok," Slav peasants); *Egy választás Magyarországon* ("An Election in Hungary"); *Pipacsok a búzában* ("Wild Poppies in the Wheatfield"); *A tekintetes vármegye* ("The Worshipful County"); *Ne okoskodj Pista* ("Don't reason, Pista"); *Szent Péter esernyője* ("St Peter's Umbrella," translated from the original into English by Miss B. W. Worswick), &c. Mikszáth has had considerable influence upon other writers. Such are Victor Rákosi (*Sipulus tárcái*, "The Essays of Sipulus"; *Rejtett fészkek*, "Hidden Nests"); Stephen Móra (*Atyánkfiai*, "Our Compatriots"); Alexius Benedek, the author of numerous distinctly sympathetic and truly Magyar tales, fables, and novels, one of the most gifted and deserving literary workers of modern Hungary (*Huszár Anna*, "Anna Huszar"; *Egy szalmaözvegy levelei*, "Letters of a grass-widow"; *A sziv könyve*, "The Book of the Heart"; *Katalin*, "Catherine"; *Csendes órák*, "Quiet Hours"; *Testamentum és hat levél*, "Last Will and Six Letters," translated into German by Dr W. Schönwald, &c.); Géza Gárdonyi (several novels containing the adventures, observations, &c., of Mr Gabriel Gőre; *A kékszemü Davidkáné*, "Blue-eyed Mrs Dávidka"; *A Kátsa*, scenes from gypsy life): Charles Murai (*Vig történetek*, "Jolly Stories"; *Bandi*, a collection of short tales): Stephen Bársony (*Csend*, "Silence"; *A Kaméleon-leány*, "The Chamæleon Girl, and other Stories"; *Erdőn-mezőn*, "In Wood and Field"). The third class of Magyar novelists comprises those cosmopolitan writers who take their method of work, their inspiration, and even many of their subjects from foreign authors, chiefly French, German, Russian, and also Norwegian. A people with an intense national sentiment, such as the Hungarians, do not as a rule incline towards permanent admiration of foreign-born or imported literary styles; and accordingly the work of this class of novelists has frequently met with very severe criticism on the part of various Magyar critics. Yet it can scarcely be denied that several of the "foreign" novelists have contributed a wholesome, if not quite Magyar, element of form or thought to literary narrative style in Hungary. Probably the foremost among them is Sigismund Justh, who died prematurely in the midst of his painful attempt at reconciling French "realistic" modes of thought with what he conceived to be Magyar simplicity (*A puszta könyve*, "The Book of the Puszta," prairie of Hungary; *A Pénz legendája*, "The Legend of Money"; *Gányó Julcsa*, "Juliet Gányó"; *Fuimus*). Other novelists belonging to this school are: Desiderius Malonyai (*Az utolsó*, "The Last"; *Judith könyve*, "The Book of Judith"; *Tanulmányfejek*, "Typical Heads"); Julius Pekár (*Dodo főhadnagy problémái*, "Lieutenant Dodo's Problems"; *Az aranykesztyűs kisasszony*, "The Maid with the Golden Gloves"; *A szoborszép asszony*, "The Lady as Beautiful as a Statue"; *Az esztendo legendája*, "The Legend of the Year"); Thomas Kobor (*Aszfalt*, "Asphalt"; *Ő akarta*, "He Wanted It"; *A csillagok felé*, "Towards the Stars"); Stephen Szomaházy (*Huszonnégy óra*, "Twenty-four Hours"; *A Clairette Keringő*, "The Clairette Valse"; *Páratlan szerdák*, "Incomparable Wednesdays"; *Nyári felhők*, "Clouds of Summer"); Zoltán Thury (*Ullrich főhadnagy és egyéb történetek*, "Lieutenant Ullrich and other Tales"; *Urak és parasztok*, "Gentlemen and Peasants"); also Desiderius Szomory, Ödon Gerő, Árpád Abonyi, Koloman Szántó, Edward Sas, Julius Vértesi, Tibor Dénes, Ákos Pintér, the Misses Janka and Stéphanie Wohl, Mrs Sigismund Gyarmathy, and others. In the fourth class may be grouped such of the latest Hungarian novelists as have tried, and on the whole succeeded, in clothing their ideas and characters in a style peculiar to themselves. Besides Stephen Petelei (*Jetti*, a name—"Henrietta"—*Felhők*, "Clouds") and Zoltán Ambrus (*Pókháló Kisasszony*, "Miss Cobweb"; *Gyanu*, "Suspicion"), must be mentioned especially Francis Herczeg, who has published a number of very interesting studies of Hungarian social life (*Simon Zsuzsa*, "Susanna Simon"; *Fenn és lenn*, "Above and Below"; *Egy leány története*, "The History of a Girl"; *Idegenek között*, "Amongst Strangers"); Alexander Bródy, who brings a delicate yet resolute analysis to unfold the mysterious and fascinating inner life of persons suffering from overwrought nerves or overstrung mind (*A kétlelkü asszony*, "The Double-Souled Lady"; *Don Quixote kisasszony*, "Miss Don Quixote"; *Faust orvos*, "Faust the Physician"; *Tündér Ilona*, *Rejtelmek*, "Mysteries"; *Az ezüst kecske*, "The Silver Goat");

and Edward Kabos, whose sombre and powerful genius has already produced works, not popular by any means, but full of great promise. In him we may trace the influence of Nietzsche's philosophy (*Koldusok*, "Beggars"; *Vándorok*, "Wanderers"). To this list we must add the short but incomparable *feuilletons* (*tárczalevelek*) of Dr Adolf Ágai (writing under the *nom de plume* of Porzó), whose influence on the formation of modern Hungarian literary prose is hardly less important than the unique *esprit* and charm of his writings.

Dramatic literature, liberally supported by the king and the government, and aided by magnificent theatres in the capital and also in the provinces (the finest provincial theatre is in Kolozsvár, in Transylvania), has developed remarkably. The Hungarians have the genuine dramatic gift in abundance; they have, moreover, actors and actresses of the first rank. In the modern drama three great and clearly differentiated groups may be distinguished. First the neo-romantic group, whose chief representatives are Eugen Rákosi, Louis Dóczi (born 1845), who, in addition to *Csók* ("The Kiss"), has written *Utolsó szerelem* ("Last Love"), *Széchy Mária* ("Maria Széchy"), *Vegyes Párok* ("Mixed Couples"). In these and other dramatic writings, more remarkable perhaps for poetic than for stage effects, Dóczi still maintains his brilliancy of diction and the delicacy of his poetic touch. To the same school belong Louis Bartók, Anton Váradi, and Alexander Somló. The next group of Hungarian dramatists is dominated by the master spirit of Gregor Csiky (1842–1891), who in his short but very active life furnished his country with a great number of society dramas, some gay, others semi-serious, but nearly all of them eminently dramatic, caustic, presenting real types of character in language incisive and moderate. In addition to his *Proletárok* (perhaps his masterpiece), Csiky wrote: *Czifra nyomorúság* ("Sham Splendour"), *A Stomfay-család* ("The Stomfay Family"), *Mukányi*, *Nora*, *Bozóti Márta*, *Jó Fülöp* ("Good Philip"), *A Kaviár*, *Két szerelem* ("Two Loves"), *Örök törvény* ("Eternal Law"), *Petneházy*, &c. Among Csiky's most promising disciples is Francis Herczeg (already mentioned as a novelist), author of the successful society comedy, *A Gyurkovics leányok* ("The Misses Gyurkovics"), *Három testőr* ("Three Guardsmen"), *Honty háza* ("The House of Honty"). Árpád Berczik's *Nézd meg az anyját* ("Look at her Mother"), *A protekczió* ("Patronizing"), also followed on the lines of Csiky. The third group of dramatic writers take their subjects, surroundings, and diction from the folk-life of the villages (*népszinmu*, "folk-drama"). The greatest of these dramatists has so far been Edward Tóth (*Toloncz*, "The Ousted Pauper"). Amongst his numerous followers, who have, however, sometimes vulgarized their figures and plots, may be mentioned Tihamér Almási (*Milimári*, *A Miniszterelnök bálja*, "The Ball of the Premier") and Alexander Somló.

In philosophy there has been a remarkable increase of activity, partly assimilative or eclectic, and partly original. Peter Bihari and Maurice Kármán have in various writings spread the ideas of Herbart. After the school of Comte, yet to a large extent original, is the *Az ember és világa* ("Man and his World") of Charles Böhm, who in 1881 started a philosophical review (*Magyar Filozofiai Szemle*), subsequently edited by Joseph Bokor, a vigorous thinker. Realism, more particularly of the Wundt type, is represented by Emericus Pauer, *Az ethikai determinismus* ("Ethical Determinism"), and Eugen Posch (*Az időről*, "On Time"). On a Thomistic basis John Kiss edits a philosophical review (*Bölcseleti Folyóirat*); on similar lines have been working Ákos Mihályfi, Répássy, Augustin Lubrich, and others. Neo-Hegelianism is cultivated by Eugen Schmitt, efficiently assisted by Joseph Alexander Simon (*Az egységes és reális természet filozofia alapvonalai*, "Outlines of a Uniform and Realistic Philosophy of Nature"). F. Medveczky (formerly a German author under the name of Fr. von Bärenbach) espouses Neo-Kantism (*Társadalmi elméletek és eszmények*, 1887, "Social Theories and Ideals"). The Hungarian scholar Samuel Brassai published, in 1896, *Az igazi pozitiv filozofia* ("The True Positive Philosophy"). Amongst the ablest and most zealous students of the history of philosophy are Bernhard Alexander, under whose editorship, aided by Joseph Bánoczi, a series of the works of the world's great thinkers has appeared; Andrew Domanovszky, author of an elaborate History of Philosophy; Julius Gyomlai, translator of Plato; Eugen Péterfy, likewise translator of philosophical works, &c.

Juristic literature has been stimulated by the activity in positive legislation. On 1st January 1900 a new criminal code, thoroughly modern in spirit, was put in force; and in 1901 a Civil Code Bill, to replace the old Hungarian customary system, was introduced. Among the newer writers on common and commercial law may be mentioned Wenczal, Zlinsky, Zögöd, Gustave Schwarz, Alexander Plósz, Francis Nagy, and Neumann; on constitutional law, Korbuly, Boncz, Stephen Kiss, Ernest Nagy, Kmety, Arthur Balogh, Ferdinandy, Bela Grünwald, Julius Andrássy, and Emeric Hajnik; on administration, George Fésüs, Kmety, and Csiky; on finance, Mariska, Exner, and László. Among the later writers on statistics, moreover, have been Konek, Keleti, Láng, Földes, Jekelfalussy, Vorgha, Körösy, Ráth, and Vizaknai.

On subjects of politics, amongst the more important works are the various monographs of Gustavus Beksics on the Dualism of Austria-Hungary, on the "New Foundations of Magyar Politics" (*A magyar politika uj alapjai*, 1899), on the Rumanian question, &c.; the writings of Emericus Bálint, Ákos Beöthy, Victor Concha (systematic politics), L. Ecsery, Géza Ferdinandy (historical and systematic politics), Árpád Zigány, Béla Földes (political economy), Julius Mandello (political economy), Alexander Matlekovics (Hungary's administrative service; *Államháztartás*, 3 vols.), J. Pólya (agrarian politics), M. Somogyi (sociology), and the late Augustus Pulszky.

In history there has been great activity. The millennial festivities in 1896 gave rise to the publication of what was then the most extensive history of the Hungarian nation (*A magyar nemzet története*, 1895–1901), ten large and splendidly illustrated volumes, edited by Alexander Szilágyi, with the collaboration of the best specialists of modern Hungary, Robert Fröhlich, B. Kuzsinszky, Géza Nagy, H. Marczali, Anton Pór, Schönherr, V. Fraknói, Árpád Károlyi, David Angyal, Coloman Thaly, Géza Ballagi.

Literary criticism is actively pursued. Among the more authoritative writers Paul Gyulai and Zsolt Beöthy represent the conservative school; younger critics, like Béla Lázár, Alexander Hevesi, H. Lenkei, Zoltan Ferenczy, Aladár Ballagi, Ladislas Négyessy, have shown themselves somewhat too ready to follow the latest Norwegian or Parisian sensation.

Hunstanton, a seaside resort of England, on the east shore of the Wash, in Norfolk, 15 miles by rail north by east from King's Lynn. It has a good beach, a golf-course, a fine Decorated 14th-century church, the (Tudor)

hall of the L'Estrange family, a convalescent home (1871), a pier, and a lighthouse, 109 feet high, casting its beams 16 miles. Nine miles to the south is Sandringham, the country seat of King Edward VII. when prince of Wales. Population (1901), 1893.

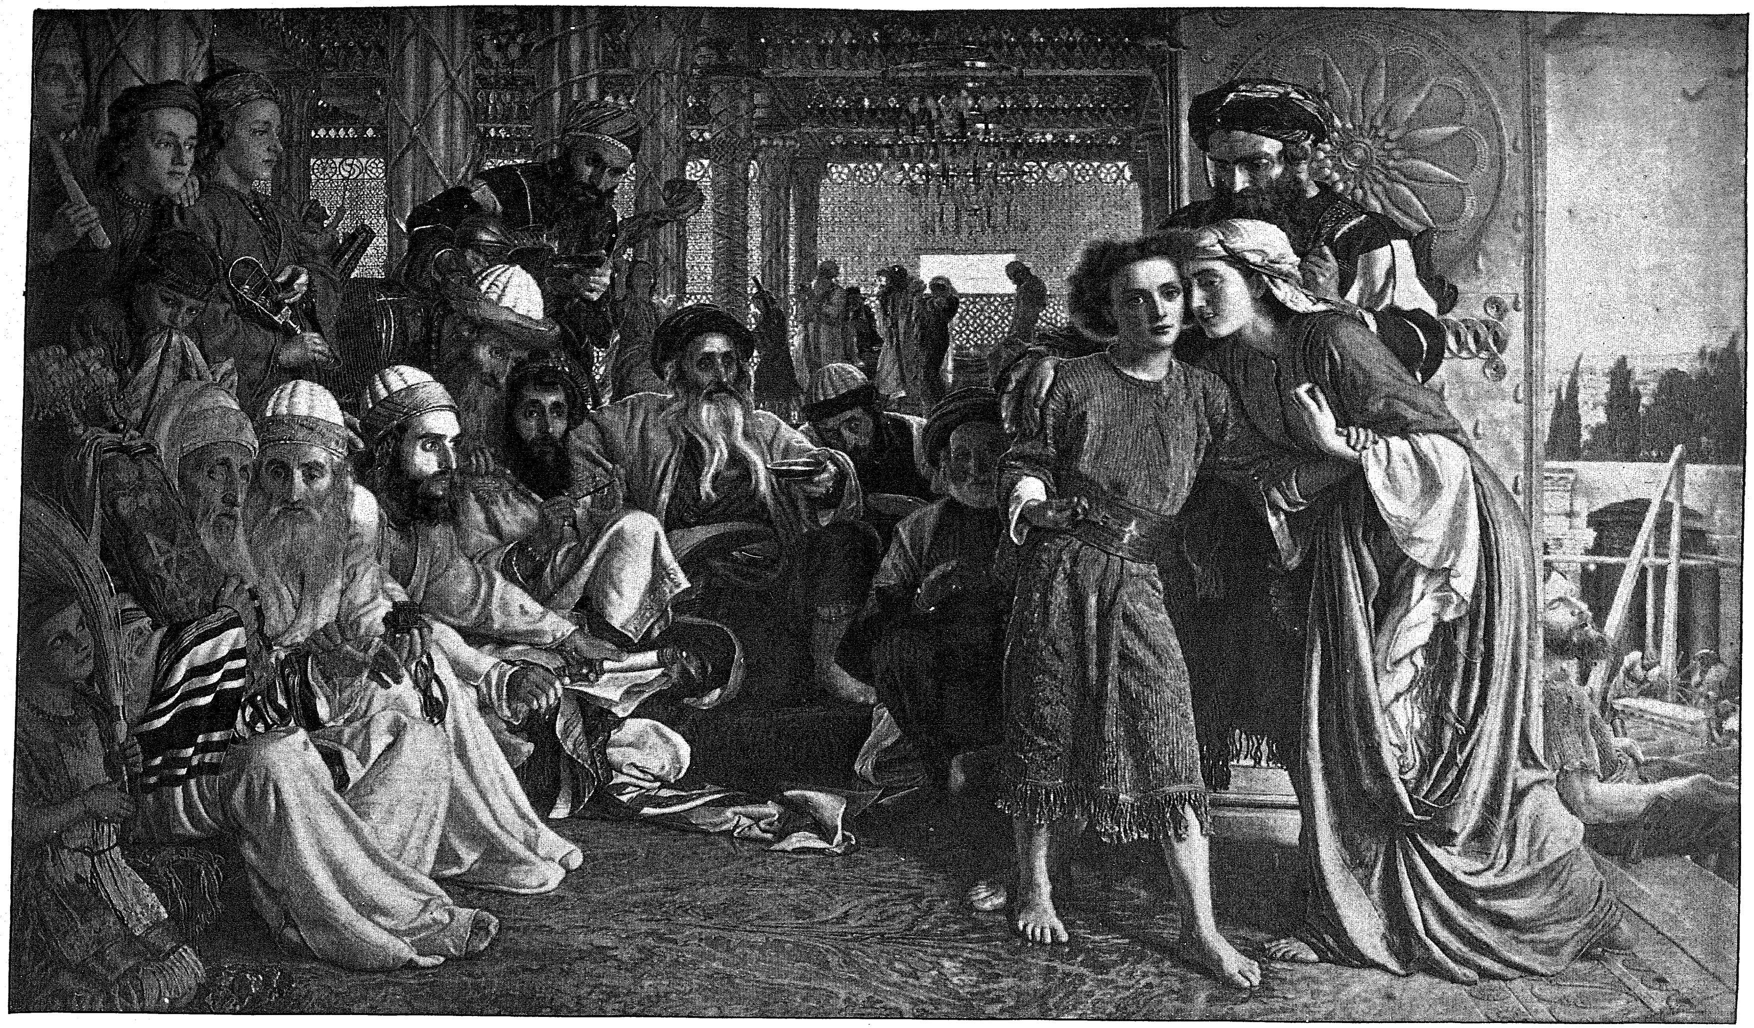
Hunt, Alfred William (1830–1896), English painter, son of Andrew Hunt, a landscape painter, was born at Liverpool in 1830. He began to paint while he was still a boy at the Liverpool Collegiate School; but as the idea of adopting the artist's profession was not favoured by his father, he went in 1848 to Corpus Christi College, Oxford. His career there was distinguished; he won the Newdigate Prize in 1851, and became a Fellow of Corpus in 1858. He did not, however, abandon his artistic practice, for, encouraged by Ruskin, he exhibited at the Royal Academy in 1854, and thenceforward regularly contributed landscapes in oil and water-colour to the London and provincial exhibitions. In 1861 he married, gave up his Fellowship, and was elected an Associate of the Royal Society of Painters in Water-Colours, receiving full membership three years later. His work is distinguished mainly by its exquisite quality and a poetic rendering of atmosphere. Hunt died on 3rd May 1896. Mrs A. W. Hunt (*née* Margaret Raine) is the writer of several works of fiction; and one of her daughters, Miss Violet Hunt, has also won distinction as a novelist.

See FREDERICK WEDMORE. "Alfred Hunt," *Magazine of Art*, 1891; *Exhibition of Drawings in Water Colour by Alfred William Hunt*, Burlington Fine Arts Club (1897).

Hunt, Henry Jackson (1819–1889), American artillerist, was born in Detroit, Mich., on 14th September 1819, graduated at the U.S. Military Academy in 1839, and became an expert in light artillery. When he was promoted to the rank of major, in May 1861, he was made chief of artillery in the Washington defences, and commanded the artillery reserve in the Virginia operations (1862–65), his services at Gettysburg being of the utmost value. He rose to be major-general of volunteers. By writing reports and papers and serving on various boards he was the foremost contributor to the effective use of artillery during the Civil War. He retired in 1883, and served as governor of the Soldiers' Home, Washington, D.C., until his death, on 11th February 1889.

Hunt, Richard Morris (1828–1895), American architect, was born in Brattleboro, Vermont, 28th October 1828. He studied in Europe (1843–1854), mainly in the École des Beaux Arts at Paris. In 1854 he was appointed on the architectural staff of the Louvre, and under Hector Lefuel designed the Pavillon de la Bibliothèque, opposite the Palais Royal. Next year he returned to New York, where he followed his profession until his death. In 1855 he was employed on the extension of the Capitol at Washington. He built the Lenox Library, the Stuyvesant and the *Tribune* buildings in New York. For the Administration Building at the World's Columbian Exposition at Chicago in 1893 he received the gold medal of the Institute of British Architects. Among the most noteworthy of his domestic buildings are the residences of Mr W. K. Vanderbilt and Mr Henry G. Marquand in New York City; Mr George W. Vanderbilt's palatial residence at Biltmore, North Carolina; and Mr Cornelius Vanderbilt's "The Breakers" at Newport, R.I. He was one of three foreign members of the Italian Society of St Luke's, an honorary and corresponding member of the Académie des Beaux Arts and of the Royal Institute of British Architects, and a Chevalier of the Legion of Honour. He was the first to command respect in foreign countries for American architecture, and was the leader of a school that has established in the United States the manner and the traditions of the Beaux Arts. He took a prominent part in the founding of the American Institute of Architects. His talent was eminently practical; and he was almost equally successful in the ornate style of the early Renaissance in France, in the picturesque style of his comfortable villas, and the monumental style of the Lenox Library. He died 31st July 1895.

Hunt, William Holman (1827–——), English artist, was born in London on 2nd April 1827. An ancestor on his father's side bore arms against Charles I., and went over to Holland, where he fought in the Protestant cause. He returned with William III., but the family failed to recover their property. Holman Hunt's father was the manager of a City warehouse, with tastes superior to his position in life. He loved books and pictures, and encouraged his son to pursue art as an amusement, but not as a profession. At the age of twelve and a half young Holman Hunt was placed in a City office, but he employed his leisure in reading, drawing, and painting, and at the age of sixteen began an independent career as an artist. When he was between seventeen and eighteen he entered the Royal Academy schools, where he soon made acquaintance with his lifelong friend John Everett Millais, then a boy of fifteen. In 1846 Holman Hunt sent to the Royal Academy his first picture ("Hark!"), which was followed by "Dr Rochecliffe performing Divine Service in the Cottage of Joceline Joliffe at Woodstock," in 1847, and "The Flight of Madeline and Porphyrio" (from Keats's *Eve of St Agnes*) in 1848. In this year he and Millais, with the co-operation of Dante Gabriel Rossetti and others, initiated the famous Pre-Raphaelite movement in art, which aimed at the exact imitation of nature and perfect sincerity of workmanship. Typical examples of the new creed were furnished in the next year's Academy by Millais's "Isabella" and Holman Hunt's "Rienzi vowing to obtain Justice for the Death of his Young Brother." This last pathetic picture was sold to Mr Gibbons for £105, and was succeeded in 1850 by "A Converted British Family sheltering a Christian Missionary from the Persecution of the Druids" (bought by Mr Combe, of the Clarendon Press, Oxford, for £150), and in 1851 by "Valentine protecting Sylvia from Proteus." This scene from *The Two Gentlemen of Verona* was very warmly praised by Ruskin (in letters to *The Times*), who declared that as studies both of drapery and of every minor detail there had been nothing in art so earnest and complete since the days of Albert Dürer. It gained a prize at Liverpool, and is reckoned as the finest of his earlier works. In 1852 he exhibited "A Hireling Shepherd," a picture of an English "hireling" sporting with a pretty country girl in a sunny meadow while the sheep break into the corn. "Claudio and Isabella," from *Measure for Measure*, and a brilliant study of the Downs near Hastings, called in the catalogue "Our English Coasts, 1852" (since generally known as "Strayed Sheep"), were exhibited in 1853. For three of his works he was awarded prizes of £50 and £60 at Liverpool and Birmingham, but in 1851 he had been so much discouraged by the difficulty of selling his pictures, that he had resolved to give up art and learn farming with a view to emigration. In 1854 he achieved his first great success by the famous picture of "The Light of the World," an allegorical representation of Christ knocking at the door of the human soul. This work produced what was perhaps the greatest effect of any religious painting of the century. "For the first time in England," wrote William Bell Scott, "a picture became



"The Finding of our Saviour in the Temple." By W. Holman Hunt.

(By permission of Corporation of Birmingham.)

a subject of conversation and general interest from one end of the island to the other, and indeed continued so for many years." "The Awakening Conscience," exhibited at the same time, depicted a tragic moment in a life of sin, when a girl, stricken with memories of her innocent childhood, rises suddenly from the knees of her paramour. The inner meaning of both these pictures was explained by Ruskin in letters to *The Times* in May 1854. "The Light of the World" was purchased by Mr Combe, and was given by his wife to Keble College.

In January 1854 Holman Hunt left England for Syria and Palestine with the desire to revivify on canvas the facts of Scripture history "surrounded by the very people and circumstances of the life in Judæa of old days." The first fruit of this idea, which may be said to have dominated the artist's life, was "The Scapegoat," a solitary outcast animal standing alone on the salt-encrusted shores of the Dead Sea, with the mountains of Edom in the distance, seen under a gorgeous effect of purple evening light. It was exhibited at the Royal Academy in 1856, together with three Eastern landscapes. His next picture (1860), one of the most elaborate and most successful of his works, was "The Finding of our Saviour in the Temple" (see Plate). Like all his important pictures, it was the work of years. Many causes contributed to the delay in its completion, including a sentence of what was tantamount to excommunication (afterwards revoked) passed on all Jews acting as models. Thousands crowded to see this picture, which was exhibited in London and in many other of the principal towns of England. It was purchased by a dealer named Gambart for £5500, and was engraved in line by Monsieur Blanchard. It is now in the Art Gallery at Birmingham, the gift of Mr Middlemore, M.P. Holman Hunt's next great religious picture was "The Shadow of Death" (exhibited separately in 1873), an imaginary incident in the life of our Lord, who, lifting His arms with weariness after labour in His workshop, throws a shadow on the wall as of a man crucified, which is perceived by His mother. This work was presented to Manchester by Sir William Agnew. Meanwhile there had appeared at the Royal Academy in 1861 "A Street in Cairo: The Lanternmaker's Courtship," and in 1863 "The King of Hearts," and a portrait of the Right Hon. Stephen Lushington, D.C.L. In 1866 came "Isabella and the Pot of Basil," "London Bridge on the Night of the Marriage of the Prince of Wales," and "The Afterglow," which were exhibited together in a private gallery and drew great attention. In 1867 Holman Hunt sent a charming head of "A Tuscan Girl" to the Grosvenor Gallery and two pictures to the Royal Academy. These were "Il dolce far niente" and a lifelike study of pigeons in rain called "The Festival of St Swithin," now in the Taylor Building, Oxford, with many others of this artist's works. After two years' absence Holman Hunt returned to Jerusalem in 1875, where he was engaged upon his great picture of "The Triumph of the Innocents," which proved to be the most serious labour of his life. The subject is an imaginary episode of the flight into Egypt, in which the Holy Family are attended by a procession of the Holy Innocents, marching along the waters of life and illuminated with unearthly light. Its execution was delayed by an extraordinary chapter of accidents. For months he waited in vain for the arrival of his materials, and at last he unfortunately began on an unsuitable piece of linen procured in despair at Jerusalem. Other troubles supervened, and when he arrived in England he found his picture in such a state that he was compelled to abandon it and begin again. The new version of the work, which is somewhat larger and changed in several points, was not completed till 1885. In the meanwhile the old picture was relined and so skilfully treated that the artist was able to complete it satisfactorily; so that now there are two pictures of "The Triumph of the Innocents," one of which is in the Art Gallery at Liverpool and the other in that at Birmingham. The pictures exhibited between 1875 and 1885 included "The Ship," a realistic picture of the deck of a passenger ship by night (1878), and portraits of his son (1880), Sir Richard Owen (1881), and Dante Gabriel Rossetti (1884). All of these were exhibited at the Grosvenor Gallery, where they were followed by "The Bride of Bethlehem" (1885), "Amaryllis," and a portrait of his son (tracing a drawing on a window) in 1886. In 1880 Holman Hunt delivered a lecture at the Society of Arts on the preparation of artists' materials, and in 1886 a collection of thirty-two of his works was exhibited at the Fine Art Society. His most important later work is "May-Day, Magdalen Tower," a record of the service of song which has been held on the tower of Magdalen, Oxford, at sunrise on May-Day from time immemorial. The subject had

William Holman Hunt.
(From a photograph by Elliott and Fry, London.)

interested the artist for a great many years, and, after "The Triumph of the Innocents" was completed, he worked at it with his usual devotion, climbing up the tower for weeks together in the early morning to study the sunrise from the top. This radiant poem of the simplest and purest devotion was exhibited at the Gainsborough Gallery in Old Bond Street in 1891. He continued to send occasional contributions to the exhibitions of the Royal Water-Colour Society, to the New Gallery, and to the New English Art Club. One of the most remarkable of his later works (New Gallery, 1899) is "The Miracle of Sacred Fire in the Church of the Sepulchre, Jerusalem," which takes place on the morning of the Greek Easter Eve, in a rotunda round the shrine. The picture is crowded with pilgrims, who, wild with religious excitement, improvise scenes from the Passion while waiting for the miraculous burst of flame.

By his strong and constant individuality, no less than by his peculiar methods of work, Mr Holman Hunt holds a somewhat isolated position among artists. He remained entirely unaffected by all the various movements in the art-world after 1850, without budging one iota from his early principles and practice. His ambition was always "to serve as high priest and expounder of the excellence of the works of the Creator." The list of his works is a short

one; he spent too much labour on each work to complete many; but perhaps no painter of the 19th century has produced so great an impression by a few pictures as the painter of "The Light of the World," "The Scapegoat," "The Finding of our Saviour in the Temple," and "The Triumph of the Innocents." In 1856 he executed six designs for the illustrated edition of Tennyson's poems, and has made many illustrations for other works. As a writer Mr Holman Hunt is known by articles in the *Contemporary Review* on "The Pre-Raphaelite Brotherhood," another on "The Proper Mode and Study of Drawing" in the *Magazine of Art*, and one on "Pre-Raphaelitism" in *Chambers's Encyclopædia*. He was engaged in 1901 on a *History of Pre-Raphaelitism*.

Hunter, William Alexander (1844–1898), Scottish jurist and politician, was born in Aberdeen, 8th May 1844, and educated at the local grammar school and university, where he carried off the highest honours and many prizes. He entered the Middle Temple, and was called to the English bar in 1867, but then was occupied mainly with teaching. In 1869 he was appointed Professor of Roman Law at University College, London, and in 1878 Professor of Jurisprudence, resigning that chair in 1882. His name became well known during this period as the author of a standard work on Roman law, together with a smaller introductory volume for students. After 1882, however, Hunter took up politics, in which he held Radical views. He was elected to Parliament for Aberdeen in 1885, and in the House of Commons was a prominent supporter of Charles Bradlaugh. He was the first to advocate old age pensions, and in 1890 carried a proposal to free elementary education in Scotland. In 1895, however, his health broke down; he retired from Parliament in 1896, and died 21st July 1898.

Hunter, Sir William Wilson (1840–1900), British publicist, son of Andrew Galloway Hunter, a Glasgow manufacturer, was born at Glasgow on 15th July 1840. He was educated at Glasgow University (B.A. 1860), Paris, and Bonn, acquiring a knowledge of Sanscrit, and passing first in the competition for the Indian Civil Service in 1861. Posted in the remote district of Birthum, in the lower provinces of Bengal, he began collecting local traditions and records, which formed the materials for his novel and suggestive publication, entitled *The Annals of Rural Bengal*, a book which did much to stimulate public interest in the details of Indian administration. He also compiled *A Comparative Dictionary of the Non-Aryan Languages of India*, a glossary of dialects based mainly upon the collections of Brian Houghton Hodgson, which testifies to the industry of the writer but contains much immature philological speculation. In 1872 he brought out two attractive volumes on the province of Orissa and its far-famed temple of Jagannath. In 1869 Lord Mayo asked Hunter to submit a scheme for a comprehensive statistical survey of the Indian empire. The work involved the compilation of a number of local gazetteers, in various stages of progress, and their consolidation in a condensed form upon a single and uniform plan. The conception was worthy of the gigantic projects formed by Arthur Young and Sir John Sinclair at the close of the 18th century, and the fact that it was successfully carried through between 1869 and 1881 was owing mainly to the energy and determination of Hunter. The early period of his undertaking was devoted by Hunter to a series of tours which took him into every corner of the peninsula and put him into direct communication with the local officials. He himself undertook the supervision of the statistical accounts of Bengal (20 vols. 1875–77) and of Assam (2 vols. 1879). The various statistical accounts, when completed, comprised no fewer than 128 volumes. The immense task of condensing this mass of material proceeded concurrently with their compilation, an administrative feat which enabled *The Imperial Gazetteer of India* to appear in 9 volumes in 1881 (second edition in 14 volumes, 1885–87). Hunter adopted a transliteration of vernacular place-names, by which means the correct pronunciation is ordinarily indicated; but hardly sufficient allowance was made for old spellings consecrated by history and long usage. Hunter's own article on India was published in 1880 as *A Brief History of the Indian Peoples*, and has been widely translated and utilized in Indian schools. A revised form was reissued in 1895, under the title of *The Indian Empire: its People, History, and Products.* In 1882 Hunter, as a member of the Governor-General's council, presided over the Commission on Indian Education; in 1886 he was elected Vice-Chancellor of the University of Calcutta. In 1887 he retired from the service, was created K.C.S.I., and settled at Oaken Holt, near Oxford. He arranged with the Clarendon Press to publish a series of *Rulers of India*, to which he himself contributed volumes on Dalhousie (1890) and Mayo (1892). He had previously, in 1875, written an official *Life of Lord Mayo*, in two volumes. He also wrote a weekly article on Indian affairs for *The Times*. But the great task to which he applied himself on his settlement in England was a history upon a large scale of the *British Dominion in India*, two volumes of which only had appeared when he died, carrying the reader barely down to 1700. He was much hindered by the confused state of his materials, a portion of which he arranged and published in 1894 as *Bengal Manuscript Records*, in three volumes. A delightful story, *The Old Missionary* (1895), and *The Thackerays in India* (1897), a gossipy volume which appeals to all readers of *The Newcomes*, may be regarded as the relaxations of an Anglo-Indian amid the stress of severer studies. In the winter of 1898–99, in consequence of the fatigue incurred in a journey to the Caspian and back, on a visit to the sick-bed of one of his two sons, Hunter was stricken down by a severe attack of influenza, which affected his heart. He died at Oaken Holt on 6th February 1900. (T. SE.)

Hunting.—When railways were first started in England, dismal prophecies were made that the end of hunting would speedily be brought about. The result on the whole has been the reverse. In some counties, of course, the sport has suffered. On the other hand, townsmen who formerly would have been too far from a meet can now secure transport for themselves and their horses in all directions; and as a consequence, meets of certain packs are not advertised because of the number of strangers who would be induced to attend. The sport has never been so vigorously pursued as it is at the beginning of the 20th century, 19 packs of staghounds being kept in England and 4 in Ireland, 162 packs of foxhounds in England, 10 in Scotland, and 23 in Ireland, with packs of harriers and beagles too numerous to be counted. The chase of the wild stag is now carried on in the west country by the Devon and Somerset hounds, which hunt three or four days a week from kennels at Dunster; by Sir J. Amory, Bart.; by the Quantock; and by a fourth pack started in 1902. The other staghound packs

Packs.

are devoted to the capture of the carted deer, a business which is more or less of a parody on the genuine sport, but is popular for the reason that whereas with foxhounds men may have a blank day, they are practically sure of a gallop when a deer is taken out in a cart to be enlarged before the hounds are laid on. Complaints are often raised about the cruelty of what is called tame stag hunting, and it was a special subject of criticism that a pack should be kept at the Royal kennels at Ascot (abolished in 1901) and hunted by the Master of the Buckhounds; but it is the constant endeavour of all masters and hunt servants to prevent the infliction of any injury on the deer. Their efforts in this direction are seldom unsuccessful; and it appears to be a fact that stags which are hunted season after season come to understand that they are in no grave danger. Packs of foxhounds vary, from large establishments in the "Shires," the meets of which are attended by hundreds of horsemen, some of whom keep large stables of hunters in constant work—for though a man at Melton, for instance, may see a great deal of sport with half-a-dozen well-seasoned animals, the number is not sufficient if he is anxious to be at all times well mounted—to small kennels in the north of England, where the field follow on foot. The "Shires" is a recognized term, but is nevertheless somewhat vague. The three counties included in the expression are Leicestershire, Rutlandshire, and Northamptonshire. Several packs which hunt within these limits are not supposed, however, to belong to the "Shires," whereas a district of the Belvoir country is in Lincolnshire, and to hunt with the Belvoir is certainly understood to be hunting in the "Shires." The Shire hounds include the Belvoir, the Cottesmore, the Quorn, and the Pytchleys; for besides the Pytchley proper, there is a pack distinguished as the Woodland. It is generally considered that the cream of the sport lies here, but with many of the packs which are generally described as "Provincial" equally good hunting may be obtained. Round about London a man who is bent on the pursuit of fox or stag may gratify his desire in many directions. The Essex and the Essex Union, the Surrey and the Surrey Union, the Old Berkeley, the West Kent, the Burstow, the Hertfordshire, the Crawley and Horsham, the Puckeridge, as regards foxhounds; the Berkhampstead, the Enfield Chase, Lord Rothschild's, the Surrey, the West Surrey, and the Warnham, as regards staghounds, as well as the Bucks and Berks, which was substituted for the Royal Buckhounds, under the mastership of Sir R. Wilmot, Bart., are within easy reach of town.

Modern horses and hounds.

Questions are constantly raised as to whether horse and hounds have improved or deteriorated of recent years. It is probable that the introduction of scientific agriculture has brought about an increase of pace. Hounds hunt as well as ever they did, are probably faster on the whole, and in the principal hunts more thoroughbred horses are employed. For pace and endurance no hunter approaches the English thoroughbred; and for a bold man who "means going," a steeplechase horse is often the best animal that could be obtained, for when he has become too slow to win races "between the flags," he can always gallop much faster, and usually lasts much longer, than animals which have not his advantage of blood. The quondam "'chaser" is, however, usually apt to be somewhat impetuous at his fences. But it must by no means be supposed that every man who goes out hunting desires to gallop at a great pace and to jump formidable obstacles, or indeed any obstacles at all. A large proportion of men who follow hounds are quite content to do so passively through gates and gaps, with a canter along the road whenever one is available. A few of the principal packs hunt five days a week, and sometimes even six, and for such an establishment not fewer than seventy-five couples of hounds are requisite. A pack which hunts four days a week will be well supplied with anything between fifty and sixty couples, and for two days a week from twenty-five to thirty will suffice. The young hound begins cub-hunting when he is some eighteen months old, and as a rule is found to improve until his third or fourth season, though some last longer than this. Often, however, when a hound is five or six years old he begins to lack speed. Exceptional animals naturally do exceptional things, and a famous hound called Potentate is recorded by the eighth Duke of Beaufort to have done notable service in the hunting field for eleven seasons.

Hunt servants.

Servants necessary for a pack include the huntsman, the duties of whose office a master sometimes fulfils himself; two whippers-in, an earth-stopper, and often a kennel huntsman is also employed, though Lord Willoughby de Broke, an unimpeachable authority, lays it down that "the man who hunts the hounds should always feed them." In all but the largest establishments the kennel huntsman is generally called the "feeder." It is his business to look after the pack which is not hunting, to walk them out, to prepare the food for the hunting pack so that it is ready when they return, and in the spring to attend to the wants of the matrons and whelps. A kennel huntsman proper may be described as the man who does duty when the master hunts his own hounds, undertaking all the responsibilities of the huntsman except actually hunting the pack. It may be said that the first duty of a huntsman is to obtain the confidence of his hounds, to understand them and to make himself understood; and the intelligence of hounds is remarkable. If, for example, it is the habit of the huntsman to give a single note on his horn when hounds are drawing a covert, and a double note when a fox is found, the pack speedily understand the significance. The mysteries of scent are certainly no better comprehended now than they were more than a hundred years ago when Peter Beckford wrote his admirable book, *Thoughts on Hunting*, a work from which a student of the sport may still learn practically all that is to be learnt. The subject of scent is full of mysteries. The great authority already quoted, the eighth Duke of Beaufort, noted as a very extraordinary but well-known fact, for example, "that in nine cases out of ten if a fox is coursed by a dog during a run all scent ceases afterwards, even when you get your hounds to the line of the fox beyond where the dog has been." This is one of many phenomena which have always remained inexplicable. The duties of the whipper-in are to a great extent explained by his title. Whilst the huntsman is drawing the cover the whipper-in is stationed at the spot from which he can best see what is going on, in order to view the fox away, and it is his business to keep the hounds together when they have found and got away after the fox. There are many ways in which a whipper-in who is not intelligent and alert may spoil sport; indeed, the Duke of Beaufort actually went so far as to declare that "in his experience, with very few exceptions, nine days out of ten that the whipper-in goes out hunting, he does more harm than good." In woodland countries, however, a good whipper-in is really of almost as much importance as the huntsman himself; if he is not alert the hounds are likely to divide, as when running a little wide they are apt to put up a fresh fox. The earth-stopper "stops out" and "puts to"—the first expression signifying blocking, during the night, earths and drains to which foxes resort, the second performing the same duties in the morning so as to prevent the fox from getting to ground when he has

been found. In the interests of humanity care should be taken that the earth-stopper always has with him a small terrier, as it is often necessary to "stop-out" permanently; and unless a dog is run through the drain some unfortunate creature in it, a fox, cat, or rabbit, may be imprisoned and starved to death. This business is frequently performed by a gamekeeper, a *douceur* being paid him for any litter of cubs or fox found on his beat.

Cost of hunting.

With regard to the expenses of hunting, it is calculated that a master of hounds should be prepared to spend at the rate of £500 a year for every day in the week that his hounds are supposed to hunt. Taking one thing with another, this is probably rather under than over the mark, and the cost of hunting three days a week, if the thing be really properly done, will most likely be nearer £2000 than £1500. The expenses to the individual naturally vary so much that no figures can be given. As long ago as 1826 twenty-seven hunters and hacks were sold for 7500 guineas, an average of over £290; and when Lord Stamford ceased to hunt the Quorn in 1853, seventy-three of his horses fetched at auction an average of close on £200. Early in the 19th century, when on the whole horses were much cheaper than they are at present, 700 and 800 guineas are prices recorded as having been occasionally paid for hunters of special repute. A man may see some sport on an animal that cost him £40; others may consider it necessary to keep an expensive establishment at Melton Mowbray or elsewhere in the Shires, with a dozen or more 500-guinea hunters, some covert-hacks, and a corresponding staff of servants. Few people realize what enormous sums of money are annually distributed in connexion with hunting. Horses must be fed; the wages of grooms and helpers be paid; saddlery, clothing, shoeing, &c., are items; farmers, innkeepers, railway companies, fly-men, and others benefit more or less directly. (A. E. T. W.)

Huntingdon, a municipal borough and market town of England, capital of the county of Huntingdon, on the Ouse, and on the Great Northern, Great Eastern, and Midland Railways, 59 miles north from London. The recent buildings include the Montagu Institute (1897), in which are held the county council technical education classes, and which also shelters a working men's club. A new red-brick building, in the Elizabethan style, was erected in 1890 to accommodate the Archdeaconry Library (founded in 1716). The town and county hospital was enlarged in 1897, and an isolation hospital built in 1898. The large Early Decorated Trinity Union church (1868) serves both Baptists and Congregationalists. There are also a Wesleyan chapel (1878) and Salvation Army barracks. Amongst the industries should be mentioned the manufacture of carriages and perforated bricks. The town is governed by a mayor, 4 aldermen, and 12 councillors. Population (1901), 4261.

Huntingdon, capital of Huntingdon county, Pennsylvania, U.S.A., on the Juniata river, the Pennsylvania canal, and the Pennsylvania and the Huntingdon and Broad Top Mountain Railways, at an altitude of 621 feet. It contains car works and varied manufactures. Population (1880), 4125; (1890), 5729; (1900), 6053, of whom 225 were foreign-born and 122 were negroes.

Huntingdonshire, one of the south midland counties of England, bounded on the N. by Northampton, on the W. by Northampton and Bedford, and on the remaining sides by Cambridge.

Area and Population.—In 1891 the area of the ancient (geographical) county was 234,218 acres, and the population 57,761, of whom 28,419 were males and 29,342 females, showing a decrease of 1730, or at the rate of 2·9 per cent., since 1881 (59,491), as compared with a decrease at the rate of 6·6 per cent. in the ten years 1871–81; and in 1901, 57,773, or an increase of 12 since 1891. The returns of 1891 give 0·25 persons to an acre and 4·05 acres to a person. In 1891 the area of the registration county was 207,569 acres, and the population 50,289, of whom 24,750 were males and 25,539 females.

Particulars of the birth-rate, death-rate, and illegitimacy-rate, and the number of persons married per 1000 inhabitants are given in the subjoined table:—

	1871-80.	1881-90.	1889-98.	1899.
Birth-rate	31·6	27·9	26·0	25·4
Death-rate	18·5	16·4	16·0	16·6
Illegitimacy-rate (per 1000 births)	52	50	52	61
Marriage-rate	13·3	12·6	13·1	14·2

In 1891 the county contained 129 persons of Scottish birth, 140 of Irish birth, and 48 foreigners. At the same date there were 45 blind, 19 deaf and dumb, and 68 insane.

Administration, &c.—For parliamentary purposes the ancient county is divided into two divisions (Southern or Huntingdon and Northern or Ramsey), each returning one member, and part of the parliamentary borough of Peterborough (Northamptonshire). The administrative county includes the three municipal boroughs of Godmanchester, Huntingdon, and St Ives. There are one court of quarter sessions and five petty sessional divisions. The administrative county contains 99 entire civil parishes and parts of 8 others. The ancient county contains 79 ecclesiastical parishes or districts and parts of 8 others, most of them in the diocese of Ely. It is also traversed by the London and North-Western Railway.

Education.—The number of elementary schools in the county on 31st August 1900 was 88, of which 24 were board schools and 64 voluntary schools, these latter embracing 60 national Church of England schools, 1 Wesleyan school, and 3 British and other schools. The total school board receipts for the year ending 29th September 1900 amounted to £6262, inclusive of £548 income under the Agricultural Rates Act.

Agriculture.—There has been a large decrease in the areas of corn crops and of fallow since 1880, and an increase in both the permanent grass and the meadow land. The area of orchards was nearly doubled between 1885 and 1900, and the area of market gardens more than trebled between 1885 and 1895. In 1889 168,575 acres were farmed by tenants and 41,966 acres by the owners; the corresponding figures for 1895 being 177,238 and 33,412 acres, and for 1900, 179,890 and 28,461 acres respectively. Good drinking water is deficient in many parts of the county. Willows are the commonest trees.

The following table shows the areas under the different kinds of crops at the periods named:—

Year.	Area in Cultivation.	Area under Corn Crops.	Area under Green Crops.	Area of Bare Fallow.	Area under Permanent Grass.
1880	209,262	95,806	20,223	15,757	
1885	210,628	88,503	21,326	15,689	65,462
1890	210,821	81,946	19,905	13,535	76,562
1895	210,650	71,413	20,173	11,863	86,043
1900	208,351	74,359	20,410	8,902	84,151

The next table shows the number of live stock at the periods named:—

Year.	Cows and Heifers.	Other Cattle.	Total Cattle.	Horses.	Sheep.	Pigs.
1880	7499	20,814	28,313	10,969	155,059	17,475
1885	7268	22,817	30,085	10,139	131,128	19,816
1890	7895	24,056	31,951	11,004	118,208	20,997
1895	7124	20,862	27,986	11,393	101,110	21,728
1900	7642	23,104	30,746	11,027	96,459	17,443

Huntington, capital of Huntington county, Indiana, U.S.A., on the Little river, on the Wabash and Erie canal, and on the Wabash and the Erie Railways, at an altitude of 743 feet. It has water-works, natural gas, the car works of the Erie Railway, and manufactures of

wooden ware. Population (1880), 3863; (1890), 7328; (1900), 9491, of whom 621 were foreign-born.

Huntington, capital of Cabell county, West Virginia, U.S.A., on the south bank of the Ohio river, just below the mouth of the Guyandot, on the Chesapeake and Ohio and the Ohio River Railways, at an altitude of 567 feet. It possesses a level site and a regular plan. It is the division headquarters of the Chesapeake and Ohio Railway, has car and machine works, and a large trade in coal, iron ore, and lumber. Population (1880), 3174; (1890), 10,108; (1900), 11,983, of whom 242 were foreign-born and 1212 were negroes.

Huntington, Daniel (1816- ——), American artist, was born in New York, 14th October 1816. In 1835 he studied with S. F. B. Morse, and produced "A Bar-Room Politician" and "A Toper Asleep." Subsequently he painted some landscapes on the river Hudson, and in 1839 went to Rome. On his return to America he painted portraits and began the illustration of *The Pilgrim's Progress*, but his eyesight failed, and in 1844 he went back to Rome. Returning to New York in 1846, he devoted his time chiefly to portrait-painting, although he has painted many *genre*, religious, and historical subjects. He was president of the National Academy from 1862 to 1869, and was re-elected in 1877. Among his principal works are: "The Florentine Girl," "Early Christian Prisoners," "The Shepherd Boy of the Campagna," "The Roman Penitents," "Christiana and Her Children," "Queen Mary signing the Death-Warrant of Lady Jane Grey," and "Feckenham in the Tower" (1850), "Chocura" (1860), "Republican Court in the Time of Washington," containing sixty-four careful portraits (1861), "Sowing the Word" (1869), "St Jerome," "Juliet on the Balcony" (1870), "The Narrows, Lake George" (1871), "Titian," "Clement VII. and Charles V. at Bologna," "Philosophy and Christian Art" (1878), "Goldsmith's Daughter" (1884). His principal portraits are: President Lincoln, in Union League Club, New York; Chancellor Ferris of New York University; Sir Charles Eastlake and the Earl of Carlyle, the property of the New York Historical Society; President Van Buren, in the State Library at Albany; James Lenox, in the Lenox Library; Louis Agassiz (1856–57), William Cullen Bryant (1866), John A. Dix (1880), and John Sherman (1881).

Huntly, a police burgh and burgh of barony of Aberdeenshire, Scotland, at the confluence of the rivers Deveron and Bogie. It is a market town and the centre of a large agricultural district, 40¾ miles north-west of Aberdeen by rail. Its industries are agricultural implement-making, hosiery weaving, weaving of woollen cloth, and the manufacture of lamps and of boots. There are an ancient castle, a public hall, a hospital for aged persons, a public library, and a cottage hospital. The public schools have a secondary department. Population (1881), 3519; (1901), 4136.

Huntsville, capital of Madison county, Alabama, U.S.A., on a plain 10 miles north of the Tennessee river, on the Nashville, Chattanooga, and St Louis, and the Southern Railways, at an altitude of 617 feet. It contains several institutions for higher education, also railway works and cotton mills. Population (1880), 4977; (1890), 7995; (1900), 8068, of whom 143 were foreign-born and 3709 were negroes.

Hunza. See GILGIT.

Hurlford and Crookedholm, a mining town of Ayrshire, Scotland, on the river Irvine, 2 miles east-south-east of Kilmarnock by rail. It has extensive ironworks and fireclay works. There is an institute, with a hall and reading-room. Two public schools had an average attendance of 685 in 1898–99, and a Roman Catholic school, 77. Population (1881), 4385; (1891), 4205; (1901), 5246.

Huşi (*Husch* or *Hushi*), chief town of the district of Falciŭ, Rumania, on the right bank of the river Pruth, about 40 miles south-east of Jassy. It is the seat of a court of first instance, and residence of a bishop. The principal commerce is in wine. A fair is held on the 14th of September. The town is said to have been founded by the Hussites in the 15th century. The cathedral (Biserica Domnesca) was built in 1491 by Stephen the Great. The Treaty of the Pruth between Russia and Turkey was signed at Huşi in 1711. Population, 15,404, of whom about one-fourth are Jews.

Husum, a small seaport town of Prussia, province of Schleswig-Holstein, near the coast of the North Sea, the port for the North Frisian Islands, 99 miles by rail north-north-west of Hamburg. In 1898 a bronze bust of Theodor Storm, who was born in this "grey town by the sea" in 1817 and died in 1888, was unveiled in the park. Husum has large cattle markets, especially for fat cattle. Population (1885), 6267; (1900), 8268.

Hutchinson, Jonathan (1828——), English surgeon and pathologist, was born 23rd July 1828 at Selby, Yorkshire, his parents belonging to the Society of Friends. He entered St Bartholomew's Hospital, and became a member of the Royal College of Surgeons in 1850 (F.R.C.S. 1862), and rapidly came to the front as a skilful operator and a scientific inquirer. He was president of the Hunterian Society in 1869 and 1870, professor of surgery and pathology at the College of Surgeons from 1877 to 1882, president of the Pathological Society, 1879–80, of the Ophthalmological Society, 1883, of the Neurological Society, 1887, of the Medical Society, 1890, and of the Royal Medical and Chirurgical in 1894–96. In 1889 he was president of the Royal College of Surgeons. He was a member of two Royal Commissions, that of 1881 to inquire into the provision for smallpox and fever cases in the London hospitals, and that of 1889–96 on vaccination and leprosy. He also acted as honorary secretary to the Sydenham Society. A progressive and a reformer, his activity in the cause of scientific surgery and in advancing the study of the natural sciences was unwearying. His lectures on neuropathogenesis, gout, leprosy, diseases of the tongue, &c., were full of original observation; but his principal work was connected with the study of syphilis, on which he became the first living authority. He was the founder of the London Polyclinic or Postgraduate School of Medicine; and both in his native town of Selby and at Haslemere, where he acquired a good deal of land and built several houses, he started (about 1890) educational museums for popular instruction in natural history. He has published several volumes on his own subjects, was editor of the quarterly *Archives of Surgery*, and holds the Hon. LL.D. degree of both Glasgow and Cambridge.

Hutchinson, capital of Reno county, Kansas, U.S.A., in the broad bottom-land of the Arkansas river, on the north side, at an altitude of 1533 feet. It is on four railways—the Atchison, Topeka and Santa Fé, the Missouri Pacific, the Chicago, Rock Island and Pacific, and the Hutchinson and Southern. Its site is level, the plan of the city regular, and the water-supply excellent. Near by is a large deposit of rock-salt, and the chief industry is mining and shipping this commodity. Popula-

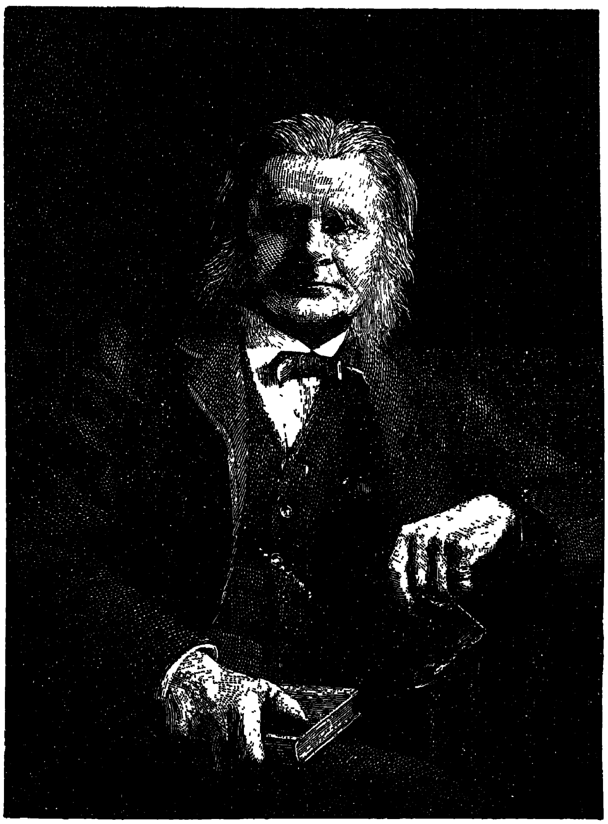
tion (1880), 1540; (1890), 8682; (1900), 9379, of whom 414 were foreign-born and 442 were negroes.

Hutton, Richard Holt (1826–1897), English writer and theologian, son of Joseph Hutton, Unitarian minister at Leeds, was born at Leeds on 2nd June 1826. His family removed to London in 1835, and he was educated at University College School and University College, where he began a life-long friendship with Walter Bagehot, of whose works he afterwards was the editor; he took his degree in 1845, being awarded the gold medal for philosophy. Meanwhile he had also studied for short periods at Heidelberg and Berlin, and in 1847 he entered Manchester New College with the idea of becoming a minister like his father, and studied there under Martineau. He did not, however, succeed in obtaining a "call" to any ministry, and for some little time his future was unsettled. He married in 1851 his cousin, Anne Roscoe, and became joint-editor with J. L. Sanford of the *Inquirer*, the principal Unitarian organ. But his innovations and his unconventional views about stereotyped Unitarian doctrines caused alarm, and in 1853 he resigned. His health had broken down, and he visited the West Indies, where his wife died of yellow fever before he returned. In 1855 Hutton and Bagehot became joint-editors of the *National Review*, a new monthly, and conducted it for ten years. During this time Hutton's theological views, influenced largely by Coleridge, and more directly by F. W. Robertson and F. D. Maurice, gradually approached more and more to those of the Church of England, which he ultimately joined. His interest in theology was profound, and he brought to it a spirituality of outlook and an aptitude for metaphysical inquiry and exposition which added a singular attraction to his writings. In 1861 he joined Mr Meredith Townsend as joint-editor and part proprietor of the *Spectator*, then a well-known Liberal weekly, which, however, was not remunerative from the business point of view. Hutton took charge of the literary side of the paper, and by degrees his own articles became and remained up to the last one of the best-known features of serious and thoughtful English journalism. The *Spectator*, which gradually became a prosperous property, was his pulpit, in which unweariyingly he gave expression to his views, particularly on literary, religious, and philosophical subjects, in opposition to the agnostic and rationalistic opinions then so current in intellectual circles, as popularized by Huxley. A man of fearless honesty, quick and catholic sympathies, broad culture, and many friends in intellectual and religious circles, he became one of the most influential journalists of the day, his fine character and conscience earning universal respect and confidence. He was an original member of the Metaphysical Society (1869). He was an anti-vivisectionist, and a member of the Royal Commission (1875) on that subject. In 1858 he had married again, his second wife, Eliza Roscoe, being a cousin of his first; she died early in 1897, and Hutton's own death followed quickly, on 9th September of the same year. Among his other publications may be mentioned *Essays, Theological and Literary* (1871; revised 1888), and *Criticisms on Contemporary Thought and Thinkers* (1894); and his opinions may be studied compendiously in the selections from his *Spectator* articles published in 1899 under the title of *Aspects of Religious and Scientific Thought*. (H. CH.)

Huxley, Thomas Henry (1825–1895), the most distinguished English biologist (if in a different field we except Charles Darwin) of the 19th century, was born on the 4th of May 1825 at Ealing, where his father, George Huxley, was senior assistant-master in the school of Dr Nicholas. This was an establishment of repute, and is at any rate remarkable for having produced two men with so little in common in after life as Huxley and Cardinal Newman. The cardinal's brother, Francis William, had been "captain" of the school in 1821. Huxley was a seventh child (as his father had also been), and the youngest who survived infancy. Of Huxley's ancestry no more is ascertainable than in the case of most middle-class families. He himself thought it sprang from the Cheshire Huxleys of Huxley Hall. Different branches migrated south, one, now extinct, reaching London, where its members were apparently engaged in commerce. They established themselves for four generations at Wyre Hall, near Edmonton, and one was knighted by Charles II. Huxley describes his paternal race as "mainly Iberian mongrels, with a good dash of Norman and a little Saxon."[1] From his father he thought he derived little except a quick temper and the artistic faculty which proved of great service to him and reappeared in an even more striking degree in his daughter, the Hon. Mrs Collier. "Mentally and physically," he wrote, "I am a piece of my mother." Her maiden name was Rachel Withers. "She came of Wiltshire people," he adds, and describes her as "a typical example of the Iberian variety." He tells us that "her most distinguishing characteristic was rapidity of thought. . . . That peculiarity has been passed on to me in full strength" (*Essays*, i. 4). One of the not least striking facts in Huxley's life is that of education in the formal sense he received none. "I had two years of a pandemonium of a school (between eight and ten), and after that neither help nor sympathy in any intellectual direction till I reached manhood" (*Life*, ii. 145). After the death of Dr Nicholas the Ealing school broke up, and Huxley's father returned about 1835 to his native town, Coventry, where he had obtained a small appointment. Huxley was left to his own devices; few histories of boyhood could offer any parallel. At twelve he was sitting up in bed to read Hutton's *Geology*. His great desire was to be a mechanical engineer; it ended in his devotion to "the mechanical engineering of living machines." His curiosity in this direction was nearly fatal; a *post-mortem* he was taken to between thirteen and fourteen was followed by an illness which seems to have been the starting-point of the ill-health which pursued him all through life. At fifteen he devoured Sir William Hamilton's *Logic*, and thus acquired the taste for metaphysics, which he cultivated to the end. At seventeen he came under the influence of Carlyle's writings. Fifty years later he wrote: "To make things clear and get rid of cant and shows of all sorts. This was the lesson I learnt from Carlyle's books when I was a boy, and it has stuck by me all my life" (*Life*, ii. 268). Incidentally they led him to begin to learn German; he had already acquired French. At seventeen Huxley, with his elder brother James, commenced regular medical studies at Charing Cross Hospital, where they had both obtained scholarships. He studied under Wharton Jones, a physiologist who never seems to have attained the reputation he deserved. Huxley said of him: "I do not know that I ever felt so much respect for a teacher before or since" (*Life*, i. 20). At twenty he passed his first M.B. examination at the University of London, winning the gold medal for anatomy and physiology; Ransom, the well-known Nottingham physician, obtaining the exhibition. In 1845 he published, at the suggestion of Wharton Jones, his first scientific paper, demonstrating the existence of a hitherto unrecognized layer in the inner sheath of hairs, a layer that has been known since as "Huxley's layer."

[1] *Nature*, lxiii. 127.

Something had to be done for a livelihood, and at the suggestion of a fellow-student, Mr (afterwards Sir Joseph) Fayrer, he applied for an appointment in the navy. He passed the necessary examination, and at the same time obtained the qualification of the Royal College of Surgeons. He was "entered on the books of Nelson's old ship, the *Victory*, for duty at Haslar Hospital." Its chief, Sir John Richardson, who was a well-known Arctic explorer and naturalist, recognized Huxley's ability, and procured for him the post of surgeon to H.M.S. *Rattlesnake*, about to start for surveying work in Torres Strait. The commander, Captain Owen Stanley, was a son of the bishop of Norwich and brother of Dean Stanley, and wished for an officer with some scientific knowledge. Besides Huxley the *Rattlesnake* also carried a naturalist by profession, John Macgillivray, who, however, beyond a dull narrative of the expedition, accomplished nothing. Huxley's future life-long friend, Sir Joseph Hooker, might have been his shipmate, but was tied by other plans. The *Rattlesnake* left England on 3rd December 1846, and was ordered home after the lamented death of Captain Stanley at Sydney, to be paid off at Chatham on 9th November 1850. The tropical seas teem with delicate surface-life, and to the study of this Huxley devoted himself with unremitting devotion. At that time no known methods existed by which it could be preserved for study in museums at home. He gathered a magnificent harvest in the almost unreaped field, and the conclusions he drew from it were the beginning of the revolution in zoological science which he lived to see accomplished.



THOMAS HENRY HUXLEY.
(From a photograph by Elliott and Fry, London.)

Cuvier (1769–1832), whose classification still held its ground, had divided the animal kingdom into four great *embranchements*. Each of these corresponded to an independent archetype, of which the "idea" had existed in the mind of the Creator. There was no other connexion between these classes, and the "ideas" which animated them were, as far as one can see, arbitrary. Cuvier's groups, without their theoretical basis, were accepted by Von Baer (1792–1876). The "idea" of the group, or archetype, admitted of endless variation within it; but this was subordinate to essential conformity with the archetype, and hence Cuvier deduced the important principle of the "correlation of parts," of which he made such conspicuous use in palæontological reconstruction. Meanwhile the "natur-philosophen," with Goethe (1749–1832) and Oken (1779–1851), had in effect grasped the underlying principle of correlation, and so far anticipated evolution by asserting the possibility of deriving specialized from simpler structures. Though they were still hampered by idealistic conceptions, they established Morphology. Cuvier's four great groups were Vertebrata, Mollusca, Articulata, and Radiata. It was amongst the members of the last class that Huxley found most material ready to his hand in the seas of the tropics. It included organisms of the most varied kind, with nothing more in common than that their parts were more or less distributed round a centre. Huxley sent home "communication after communication to the Linnean Society," then a somewhat somnolent body, "with the same result as that obtained by Noah when he sent the raven out of the ark" (*Essays*, i. 13). His important paper, *On the Anatomy and the Affinities of the Family of Medusæ*, met with a better fate. It was communicated by the bishop of Norwich to the Royal Society, and printed by it in the *Philosophical Transactions* in 1849. Huxley united, with the Medusæ, the Hydroid and Sertularian polyps, to form a class to which he subsequently gave the name of Hydrozoa. This alone was no inconsiderable feat for a young surgeon who had only had the training of a medical school. But the ground on which it was done has led to far-reaching theoretical developments. Huxley realized that something more than superficial characters were necessary in determining the affinities of animal organisms. He found that all the members of the class consisted of two membranes enclosing a central cavity or stomach. This is characteristic of what are now called the Cœlenterata. All animals higher than these have been termed Cœlemeta; they possess a distinct body-cavity in addition to the stomach. Huxley went farther than this, and the most profound suggestion in his paper is the comparison of the two layers with those which appear in the germ of the higher animals. The consequences which have flowed from this prophetic generalization of the *ectoderm* and *endoderm* are familiar to every student of evolution. The conclusion was the more remarkable as at the time he was not merely free from any evolutionary belief, but actually rejected it. The value of Huxley's work was immediately recognized. On returning to England in 1850 he was elected a Fellow of the Royal Society. In the following year, at the age of 26, he not merely received the Royal medal, but was elected on the council. With absolutely no aid from any one he had placed himself in the front rank of English scientific men. He secured the friendship of Hooker and Tyndall, who remained his life-long friends. The Admiralty retained him as a nominal assistant-surgeon, in order that he might work up the observations he had made during the voyage of the *Rattlesnake*. He was thus enabled to produce various important memoirs, especially those on certain Ascidians, in which he solved the problem of *Appendicularia*—an organism whose place in the animal kingdom Johannes Müller had found himself wholly unable to assign—and on the morphology of the Cephalous Mollusca.

Owen, who was then the leading comparative anatomist in Great Britain, was a disciple of Cuvier, and adopted largely from him the deductive explanation of anatomical

fact from idealistic conceptions. He superadded the evolutionary theories of Oken, which were equally idealistic, but were altogether repugnant to Cuvier. Huxley would have none of either. Imbued with the methods of Von Baer and Johannes Müller, his methods were purely inductive. He would not hazard any statement beyond what the facts revealed. He retained, however, as has been done by his successors, the use of archetypes, though they no longer represented fundamental "ideas" but generalizations of the essential points of structure common to the individuals of each class. He had not wholly freed himself, however, from archetypal trammels. "The doctrine," he says, "that every natural group is organized after a definite archetype . . . seems to me as important for zoology as the doctrine of definite proportions for chemistry." This was in 1853. He further stated:—"There is no progression from a lower to a higher type, but merely a more or less complete evolution of one type" (*Phil. Trans.* 1853, 63). As Chalmers Mitchell points out, this statement is of great historical interest. Huxley definitely uses the word "evolution," and admits its existence *within* the great groups. He had not, however, rid himself of the notion that the archetype was a property inherent in the group. Herbert Spencer, whose acquaintance he made in 1852, was unable to convert him to evolution (*Life*, i. 168). He could not bring himself to acceptance of the theory—owing, no doubt, to his rooted aversion from *à priori* reasoning—without a mechanical conception of its mode of operation. In his first interview with Darwin, which seems to have been about the same time, he expressed his belief "in the sharpness of the lines of demarcation between natural groups," and was received with a humorous smile (*Life*, i. 169).

The naval medical service exists for practical purposes. It is not surprising, therefore, that after his three years' nominal employment Huxley was ordered on active service. Though without private means of any kind, he resigned. The navy, however, retains the credit of having started his scientific career as well as that of Hooker and Darwin. Huxley was now thrown on his own resources, the immediate prospects of which were slender enough. As a matter of fact, he had not to wait many months. His friend Edward Forbes was appointed to the chair of Natural History in Edinburgh, and in July 1854 he succeeded him as lecturer at the School of Mines and as naturalist to the Geological Survey in the following year. The latter post he hesitated at first to accept, as he "did not care for fossils" (*Essays*, i. 15). In 1855 he married Miss H. A. Heathorn, whose acquaintance he had made in Sydney. They were engaged when Huxley could offer nothing but the future promise of his ability. The confidence of his devoted helpmate was not misplaced, and her affection sustained him to the end, after she had seen him the recipient of every honour which English science could bestow. His most important research belonging to this period was the Croonian Lecture delivered before the Royal Society in 1858 on "The Theory of the Vertebrate Skull." In this he completely and finally demolished, by applying as before the inductive method, the idealistic, if in some degree evolutionary, views of its origin which Owen had derived from Goethe and Oken. This finally disposed of the "archetype," and may be said once for all to have liberated the English anatomical school from the deductive method.

In 1859 *The Origin of Species* was published. This was a momentous event in the history of science, and not least for Huxley. Hitherto he hrd turned a deaf ear to evolution. "I took my star," he says, "upon two grounds: firstly, that . . . the evidence in favour of transmutation was wholly insufficient; and secondly, that no suggestion respecting the causes of the transmutation assumed, which had been made, was in any way adequate to explain the phenomena" (*Life*, i. 168). Huxley had studied Lamarck "attentively," but to no purpose. Lyell "was the chief agent in smoothing the road for Darwin. For consistent uniformitarianism postulates evolution as much in the organic as in the inorganic world" (*l.c.*); and Huxley found in Darwin what he had failed to find in Lamarck, an intelligible hypothesis good enough as a working basis. Yet with the transparent candour which was characteristic of him, he never to the end of his life concealed the fact that he thought it wanting in rigorous proof. Darwin, however, was a naturalist; Huxley was not. He says:—"I am afraid there is very little of the genuine naturalist in me. I never collected anything, and species-work was always a burden to me; what I cared for was the architectural and engineering part of the business" (*Essays*, i. 7). But the solution of the problem of organic evolution must work upwards from the initial stages, and it is precisely for the study of these that "species-work" is necessary. Darwin, by observing the peculiarities in the distribution of the plants which he had collected in the Galapagos, was started on the path that led to his theory. Anatomical research had only so far led to transcendental hypothesis, though in Huxley's hands it had cleared the decks of that lumber. He quotes with approval Darwin's remark that "no one has a right to examine the question of species who has not minutely described many" (*Essays*, ii. 283). The rigorous proof which Huxley demanded was the production of species sterile to one another by selective breeding (*Life*, i. 193). But this was a misconception of the question. Sterility is a physiological character, and the specific differences which the theory undertook to account for are morphological; there is no necessary nexus between the two. Huxley, however, felt that he had at last a secure grip of evolution. He warned Darwin:—"I will stop at no point as long as clear reasoning will carry me farther" (*Life*, i. 172). Owen, who had some evolutionary tendencies, was at first favourably disposed to Darwin's theory, and even claimed that he had to some extent anticipated it in his own writings. But Darwin, though he did not thrust it into the foreground, never flinched from recognizing that man could not be excluded from his theory. "Light will be thrown on the origin of man and his history" (*Origin*, ed. i., 488). Owen could not face the wrath of fashionable orthodoxy. In his Rede Lecture he endeavoured to save the position by asserting that man was clearly marked off from all other animals by the anatomical structure of his brain. This was actually inconsistent with known facts, and was effectually refuted by Huxley in various papers and lectures, summed up in 1863 in *Man's Place in Nature*. This "monkey damnification" of mankind was too much even for the "veracity" of Carlyle, who is said to have never forgiven it. Huxley had not the smallest respect for authority as a basis for belief, scientific or otherwise. He held that scientific men were morally bound "to try all things and hold fast to that which is good" (*Life*, ii. 161). Called upon in 1862, in the absence of the president, to deliver the presidential address to the Geological Society, he disposed once for all of one of the principles accepted by geologists, that similar fossils in distinct regions indicated that the strata containing them were contemporary. All that could be concluded, he pointed out, was that the general order of succession was the same. In 1854 Huxley had refused the post of palæontologist to the Geological Survey; but the fossils for which he then said that he "did not care" soon acquired importance in his eyes as supplying evidence for the support of the

evolutionary theory. The thirty-one years during which he occupied the chair of Natural History at the School of Mines were largely occupied with palæontological research. Numerous memoirs on fossil fishes established many far-reaching morphological facts. The study of fossil reptiles led to his demonstrating, in the course of lectures delivered at the College of Surgeons in 1867, on birds, the fundamental affinity of the two groups which he united under the title of Sauropsida. An incidental result of the same course was his proposed rearrangement of the zoological regions into which Sclater had divided the world in 1857. Huxley anticipated, to a large extent, the results at which botanists have since arrived: he proposed as primary divisions, Arctogæa—to include the land areas of the northern hemisphere—and Notogæa for the remainder. Successive waves of life originated in and spread from the northern area, the survivors of the more ancient types finding successively a refuge in the south. Though Huxley had accepted the Darwinian theory as a working hypothesis, he never succeeded in firmly grasping it in detail. He thought "evolution might conceivably have taken place without the development of groups possessing the characters of species" (*Essays*, v. 41). His palæontological researches ultimately led him to dispense with Darwin. In 1892 he wrote:—"The doctrine of evolution is no speculation, but a generalization of certain facts . . . classed by biologists under the heads of Embryology and of Palæontology" (*Essays*, v. 42). Earlier in 1881 he had asserted even more emphatically that if the hypothesis of evolution "had not existed, the palæontologist would have had to invent it" (*Essays*, iv. 44).

From 1870 onwards he was more and more drawn away from scientific research by the claims of public duty. Some men yield the more readily to such demands, as their fulfilment is not unaccompanied by public esteem. But he felt, as he himself said of Priestley, "that he was a man and a citizen before he was a philosopher, and that the duties of the two former positions are at least as imperative as those of the latter" (*Essays*, iii. 13). From 1862 to 1884 he served on no less than ten Royal Commissions, dealing in every case with subjects of great importance, and in many with matters of the gravest moment to the community. He held and filled with invariable dignity and distinction more public positions than have perhaps ever fallen to the lot of a scientific man in England. From 1871 to 1880 he was a secretary of the Royal Society. From 1883 to 1885 he was president. For honours he cared little, though they were within his reach; it is said that he might have received a peerage. He accepted, however, in 1892, a Privy Councillorship, at once the most democratic and the most aristocratic honour accessible to an English citizen. In 1870 Huxley was president of the British Association at Liverpool, and in the same year was elected a member of the newly constituted London School Board. He resigned the latter position in 1872, but in the brief period during which he acted, probably more than any man, he left his mark on the foundations of national elementary education. He made war on the scholastic methods which wearied the mind in merely taxing the memory; the children were to be prepared to take their place worthily in the community. Physical training was the basis; domestic economy, at any rate for girls, was insisted upon, and for all some development of the æsthetic sense by means of drawing and singing. Reading, writing, and arithmetic were the indispensable tools for acquiring knowledge, and intellectual discipline was to be gained through the rudiments of physical science. He insisted on the teaching of the Bible partly as a great literary heritage, partly because he was "seriously perplexed to know by what practical measures the religious feeling, which is the essential basis of conduct, was to be kept up, in the present utterly chaotic state of opinion in these matters, without its use" (*Essays*, iii. 397). In 1872 the School of Mines was moved to South Kensington, and Huxley had, for the first time after eighteen years, those appliances for teaching beyond the lecture room, which to the lasting injury of the interests of the biological science of Great Britain had been withheld from him by the short-sightedness of Government. Huxley had only been able to bring his influence to bear upon his pupils by oral teaching, and had had no opportunity by personal intercourse in the laboratory of forming a school. He was now able to organize a system of instruction for classes of elementary teachers in the general principles of biology, which indirectly affected the teaching of the subject throughout the country.

The first symptoms of physical failure to meet the strain of the scientific and public duties demanded of him made some rest imperative, and he took a long holiday in Egypt. He still continued for some years to occupy himself mainly with vertebrate morphology. But he seemed to find more interest and the necessary mental stimulus to exertion in lectures, public addresses, and more or less controversial writings. His health, which had for a time been fairly restored, completely broke down again in 1885. In 1890 he removed from London to Eastbourne, where after a painful illness he died on 29th June 1895.

The latter years of Huxley's life were mainly occupied with contributions to periodical literature on subjects connected with philosophy and theology. The effect produced by these on popular opinion was profound. This was partly due to his position as a man of science, partly to his obvious earnestness and sincerity, but in the main to his strenuous and attractive method of exposition. Such studies were not wholly new to him, as they had more or less engaged his thoughts from his earliest days. That his views exhibit some process of development and are not wholly consistent was, therefore, to be expected, and for this reason it is not easy to summarize them as a connected body of teaching. They may be found perhaps in their most systematic form in the volume on *Hume* published in 1879.

Huxley's general attitude to the problems of theology and philosophy was technically that of scepticism. "I am," he wrote, "too much of a sceptic to deny the possibility of anything" (*Life*, ii. 127). "Doubt is a beneficent demon" (*Essays*, ix. 56). He was anxious, nevertheless, to avoid the accusation of Pyrrhonism (*Life*, ii. 280), but the Agnosticism which he defined to express his position in 1869 suggests the Pyrrhonist *Aphasia*. The only approach to certainty which he admitted lay in the order of nature. "The conception of the constancy of the order of nature has become the dominant idea of modern thought. . . . Whatever may be man's speculative doctrines, it is quite certain that every intelligent person guides his life and risks his fortune upon the belief that the order of nature is constant, and that the chain of natural causation is never broken." He adds, however, that "it by no means necessarily follows that we are justified in expanding this generalization into the infinite past" (*Essays*, iv. 47, 48). This was little more than a pious reservation, as evolution implies the principle of continuity (*l.c.* p. 55). Later he stated his belief even more absolutely: "If there is anything in the world which I do firmly believe in, it is the universal validity of the law of causation, but that universality cannot be proved by any amount of experience" (*Essays*, ix. 121). The assertion that "There is only one method by which intellectual truth can be reached, whether the subject-matter of investigation belongs to the world of physics or to the world of consciousness" (*Essays*, ix. 126) laid him open to the charge of materialism, which he vigorously repelled. His defence, when he rested it on the imperfection of the physical analysis of matter and force (*l.c.* p. 131), was irrelevant; he was on sounder ground when he contended with Berkeley "that our certain knowledge does not extend beyond our states of consciousness" (*l.c.* p. 130). "Legitimate materialism, that is, the extension of the conceptions and of the methods of physical science to the highest as well as to the lowest phenomena of vitality, is neither more nor less than a sort of shorthand idealism" (*Essays*, i. 194). While "the substance of matter is a metaphysical unknown quality of the existence of which there is no proof . . . the non-existence of a substance of

mind is equally arguable; . . the result . . . is the reduction of the All to co-existences and sequences of phenomena beneath and beyond which there is nothing cognoscible" (*Essays*, ix. 66). Hume had defined a miracle as a "violation of the laws of nature." Huxley refused to accept this. While, on the one hand, he insists that "the whole fabric of practical life is built upon our faith in its continuity" (*Hume*, p. 129), on the other "nobody can presume to say what the order of nature must be"; this "knocks the bottom out of all *à priori* objections either to ordinary 'miracles' or to the efficacy of prayer" (*Essays*, v. 133). "If by the term miracles we mean only extremely wonderful events, there can be no just ground for denying the possibility of their occurrence" (*Hume*, p. 134). Assuming the chemical elements to be aggregates of uniform primitive matter, he saw no more theoretical difficulty in water being turned into alcohol in the miracle at Cana, than in sugar undergoing a similar conversion (*Essays*, v. 81). The credibility of miracles with Huxley is a question of evidence. It may be remarked that a scientific explanation is destructive of the supernatural character of a miracle, and that the demand for evidence may be so framed as to preclude the credibility of any historical event. Throughout his life theology had a strong attraction, not without elements of repulsion, for Huxley. The circumstances of his early training, when Paley was the "most interesting Sunday reading allowed him when a boy" (*Life*, ii. 57), probably had something to do with both. In 1860 his beliefs were apparently theistic: "Science seems to me to teach in the highest and strongest manner the great truth which is embodied in the Christian conception of entire surrender to the will of God" (*Life*, i. 219). In 1885 he formulates "the perfect ideal of religion" in a passage which has become almost famous: "In the 8th century B.C., in the heart of a world of idolatrous polytheists, the Hebrew prophets put forth a conception of religion which appears to be as wonderful an inspiration of genius as the art of Pheidias or the science of Aristotle. 'And what doth the Lord require of thee, but to do justly, and to love mercy, and to walk humbly with thy God'" (*Essays*, iv. 161). Two years later he was writing: "That there is no evidence of the existence of such a being as the God of the theologians is true enough" (*Life*, ii. 162). He insisted, however, that "atheism is on purely philosophical grounds untenable" (*l.c.*). His theism never really advanced beyond the recognition of "the passionless impersonality of the unknown and unknowable, which science shows everywhere underlying the thin veil of phenomena" (*Life*, i. 239). In other respects his personal creed was a kind of scientific Calvinism. There is an interesting passage in an essay written in 1892, "An Apologetic Eirenicon," which has not been republished, which illustrates this: "It is the secret of the superiority of the best theological teachers to the majority of their opponents that they substantially recognize these realities of things, however strange the forms in which they clothe their conceptions. The doctrines of predestination, of original sin, of the innate depravity of man and the evil fate of the greater part of the race, of the primacy of Satan in this world, of the essential vileness of matter, of a malevolent Demiurgus subordinate to a benevolent Almighty, who has only lately revealed himself, faulty as they are, appear to me to be vastly nearer the truth than the 'liberal' popular illusions that babies are all born good, and that the example of a corrupt society is responsible for their failure to remain so; that it is given to everybody to reach the ethical ideal if he will only try; that all partial evil is universal good, and other optimistic figments, such as that which represents 'Providence' under the guise of a paternal philanthropist, and bids us believe that everything will come right (according to our notions) at last." But his "slender definite creed," R. H. Hutton, who was associated with him in the Metaphysical Society, thought—and no doubt rightly—in no respect "represented the cravings of his larger nature."

From 1880 onwards till the very end of his life, Huxley was continuously occupied in a controversial campaign against orthodox beliefs. As Professor Weldon justly says of his earlier polemics:—"They were certainly among the principal agents in winning a larger measure of toleration for the critical examination of fundamental beliefs, and for the free expression of honest reverent doubt." He threw Christianity overboard bodily and with little appreciation of its historic effect as a civilizing agency. He thought that "the exact nature of the teachings and the convictions of Jesus is extremely uncertain" (*Essays*, v. 348). "What we are usually pleased to call religion nowadays is, for the most part, Hellenized Judaism" (*Essays*, iv. 162). His final analysis of what "since the second century, has assumed to itself the title of Orthodox Christianity" is a "varying compound of some of the best and some of the worst elements of Paganism and Judaism, moulded in practice by the innate character of certain people of the Western world" (*Essays*, v. 142). He concludes "That this Christianity is doomed to fall is, to my mind, beyond a doubt; but its fall will neither be sudden nor speedy" (*l.c.*). He did not omit, however, to do justice to "the bright side of Christianity," and was deeply impressed with the life of Catherine of Siena. Failing Christianity, he thought that some other "hypostasis of men's hopes" will arise (*Essays*, v. 254). His latest speculations on ethical problems are perhaps the least satisfactory of his writings. In 1892 he wrote:—"The moral sense is a very complex affair—dependent in part upon associations of pleasure and pain, approbation and disapprobation, formed by education in early youth, but in part also on an innate sense of moral beauty and ugliness (how originated need not be discussed), which is possessed by some people in great strength, while some are totally devoid of it" (*Life*, ii. 305). This is an intuitional theory, and he compares the moral with the æsthetic sense, which he repeatedly declares to be intuitive; thus:—"All the understanding in the world will neither increase nor diminish the force of the intuition that this is beautiful and this is ugly" (*Essays*, ix. 80). In the Romanes Lecture delivered in 1894, in which this passage occurs, he defines "law and morals" to be "restraints upon the struggle for existence between men in society." It follows that "the ethical process is in opposition to the cosmic process," to which the struggle for existence belongs (*Essays*, ix. 31). Apparently he thought that the moral sense in its origin was intuitional and in its development utilitarian. "Morality commenced with society" (*Essays*, v. 52). The "ethical process" is the "gradual strengthening of the social bond" (*Essays*, ix. 35). "The cosmic process has no sort of relation to moral ends" (*l.c.* p. 83); "of moral purpose I see no trace in nature. That is an article of exclusive human manufacture" (*Life*, ii. 268). The cosmic process Huxley identified with evil, and the ethical process with good; the two are in necessary conflict. "The reality at the bottom of the doctrine of original sin" is the "innate tendency to self-assertion" inherited by man from the cosmic order (*Essays*, ix. 27). "The actions we call sinful are part and parcel of the struggle for existence" (*Life*, ii. 282). "The prospect of attaining untroubled happiness" is "an illusion" (*Essays*, ix. 44), and the cosmic process in the long run will get the best of the contest, and "resume its sway" when evolution enters on its downward course (*l.c.* p. 45). This approaches pure pessimism, and though in Huxley's view the "pessimism of Schopenhauer is a nightmare" (*Essays*, ix. 200), his own philosophy of life is not distinguishable, and is often expressed in the same language. The cosmic order is obviously non-moral (*Essays*, ix. 197). That it is, as has been said, immoral is really meaningless. Pain and suffering are affections which imply a complex nervous organization, and we are not justified in projecting them into nature external to ourselves. Darwin and Wallace disagreed with Huxley in seeing rather the joyous than the suffering side of nature. Nor can it be assumed that the descending scale of evolution will reproduce the ascent, or that man will ever be conscious of his doom.

As has been said, Huxley never thoroughly grasped the Darwinian principle. He thought "transmutation may take place without transition" (*Life*, i. 173). In other words, that evolution may be accomplished by leaps and not by the accumulation of small variations. He recognized that the "struggle for existence" had not the gradual adjustment of the organism to its environment which is implied in "natural selection." In highly civilized societies he thought that the former was at an end (*Essays*, ix. 36) and had been replaced by the "struggle for enjoyment" (*l.c.* p. 40). But a consideration of the stationary population of France might have shown him that the effect in the one case may be as restrictive as in the other. So far from natural selection being in abeyance under modern social conditions, "it is," as Professor Karl Pearson points out, "something we run up against at once, almost as soon as we examine a mortality table" (*Biometrika*, i. 76). The inevitable conclusion, whether we like it or not, is that the future evolution of humanity is as much a part of the cosmic process as its past history, and Huxley's attempt to shut the door on it cannot be maintained scientifically.

Huy, a town of Belgium, in the province and 21 miles south-west of the town of Liége by rail. It is in the chief vine-growing district of the country, and the town does an important trade in wine and corn. Population (1900), 14,644.

Hwang Ho, or HOANG HO, the second largest river in China. It is known to foreigners as the Yellow river—a name which is a literal translation of the Chinese. It rises on the eastern slopes of the Kuen-lun mountains in Central

Asia, its head-waters being in close proximity to those of the Yangtse. It has a total length of about 2400 miles, and drains an area of approximately 400,000 square miles. The main stream has its source in two lakes named Charing-nor and Oring-nor, in 34° 60′ N. lat. and 98° E. long., and after flowing a south-easterly course it bends sharply to the north-west and north, entering China in the province of Kansu in lat. 36°. After passing Lanchau-fu, the capital of this province, the river takes an immense sweep to the north and north-east, until it encounters the rugged barrier ranges that here run north and south through the provinces of Shansi and Chihli. By these ranges it is bent back on its course and forced due south for 500 miles, forming the boundary between the provinces of Shansi and Shensi, until it finds an outlet eastwards at Tung Kwan—a pass which for centuries has been renowned as the gate of Asia, being indeed the sole commercial passage between central China and the West. At Tung Kwan the river is joined by its only considerable affluent in China proper, the Wei, which drains the whole of the large province of Shensi, and the combined volume of water continues its way nearly due east across the great plain to the sea. The quantity of water discharged varies very greatly at different times of the year. At low water in the winter season the discharge is only about 36,000 cubic feet per second, whereas during the summer flood it reaches 116,000 feet or more. The amount of sediment carried down is very large, though no accurate observations have been made. In the account of Lord Macartney's embassy, which crossed the Yellow river in 1792, it was calculated to be 17,520 million cubic feet a year, but this is considered to be very much over the mark. Two reasons, however, combine to render it probable that the sedimentary matter is very large in proportion to the volume of water: the first being the great fall, and the consequently rapid current over two-thirds of the river's course; the second that the drainage area is nearly all covered with deposits of loess, which, being very friable, readily gives way before the rainfall and is washed down in large quantity. The ubiquity of this loess or yellow earth, as the Chinese call it, has in fact given its name both to the river which carries it in solution and to the sea (the Yellow Sea) into which it is discharged. It is calculated by Dr Guppy (*Journal of China Branch of Royal Asiatic Society*, vol. xvi.) that the sediment brought down by the three northern rivers of China, viz., the Yangtse, the Yellow river, and the Peiho, is 24,000 million cubic feet per annum, and is sufficient to fill up the whole of the Yellow Sea and the Gulf of Pechili in the space of about 36,000 years.

Unlike the Yangtse, the Yellow river is of no practical value for navigation. The silt and sand form banks and bars at the mouth, the water is too shallow in winter and the current is too strong in summer, and, further, the bed of the river itself is continually shifting. It is this last feature which has given the Yellow river the notoriety it has unhappily obtained, and earned for it the name "China's sorrow." As the silt-laden waters debouch from the rocky bed of the upper reaches on to the plains, the current slackens, and the coarser detritus settles on the bottom. By degrees the bed rises, and the people build embankments to prevent the river from overflowing. As the bed rises the embankments must be raised too, until the stream is flowing many feet above the level of the surrounding country. As time goes on the situation becomes more and more dangerous; finally, a breach occurs, and the whole river pours over the country, carrying destruction and ruin in its wake. If the breach cannot be repaired the river leaves its old channel entirely, and finds a new exit to the sea along the line of least resistance. Such in brief has been the story of the Yellow river since the dawn of Chinese history. At various times it has discharged its waters alternately on one side or the other of the great mass of mountains forming the promontory of Shantung, and by mouths as far apart from each other as 500 miles. At each change it has worked havoc and disaster by covering the cultivated fields with two or three feet of sand and mud. Ruthless as it may seem, the river is only completing the geological task which nature has set it to do, viz., building up the great plain by adding a few feet here and there whenever it gets a chance. But the swarming inhabitants, driven from their homes for the time being, set to work to repair the disaster, and confine the giant river in its new course by new embankments. The waters dry up, the fields are again cultivated, until in the next cycle the like causes produce the like results.

The most recent great change in the river's course occurred in 1851, when a breach was made in the north embankment near Kaifungfu in Honan. At this point the river bed was some 25 feet above the plain; the water consequently forsook the old channel entirely and poured over the level country, finally seizing on the bed of a small river called the Tsing, and thereby finding an exit to the sea. Since that time the new channel thus carved out has remained the proper course of the river, the old or southerly channel being left quite dry. It required some fifteen or more years to repair damages from this outbreak, and to confine the stream by new embankments. After that there was for a time comparative immunity from inundations, but in 1882 fresh outbursts again began. The most serious of all took place in 1887, when it appeared probable that there would be again a permanent change in the river's course. By dint of great exertions, however, the Government succeeded in closing the breach, though not till January 1889, and not until there had been immense destruction of life and property. The outbreak on this occasion occurred, as all the more serious outbreaks have done, in Honan, a few miles west of the city of Kaifungfu. The stream poured itself over the level and fertile country to the southwards, sweeping whole villages before it, and converting the plain into one vast lake. The area affected was not less than 50,000 square miles, and the loss of life was computed at over one million. Since 1887 there have been a series of smaller outbreaks mostly at points lower down and in the neighbourhood of Tsinanfu, the capital of Shantung. These perpetually occurring disasters entail a heavy expense on the Government; and from the mere pecuniary point of view it would well repay them to call in the best foreign engineering skill available, an expedient, however, which has not yet recommended itself to the Chinese authorities. (G. J.)

Hybridism.—Professor Romanes represented contemporary opinion well by making his article on HYBRIDISM, in the ninth edition of this Encyclopædia, an annotated summary of Darwin's views. Darwin had shown that there was no foundation in nature for the supposed fixed law that hybrids were infertile. Some mongrels are infertile or sterile; some crosses are quite fertile; there are many curious phenomena connected with the susceptibility of the reproductive functions which make it probable that the common intersterility of species is an accidental result; as domestic animals must often have been chosen on account of a relative stability of their reproductive capacities, it is not surprising that domestic varieties should be fertile so frequently; there is no reason to suppose that natural hybridism has played any considerable part in the evolution of new species. Romanes afterwards developed his theory of *physiological selection*, in which he supposed that the appearance of differential fertility within a species was the starting-point of new species; certain individuals by becoming fertile only *inter se* proceeded along lines of modification diverging from the lines followed by the other members of the species, and thus mutual infertility was the starting-point, not the result, of specific modification. Romanes, however, did not associate his interesting theory with a sufficient number of facts, and it has left little mark in the development of the subject. A. R. Wallace, on the other hand, has argued that sterility between incipient species may have been increased by natural selection in the same fashion as other favourable variations are supposed to have been accumulated. He supposed that some "slight degree of infertility was a not infrequent accompaniment of the external differences which always arise in a state of nature between varieties and incipient species."

There are many new records as to the production of hybrids. Horticulturists have been extremely active and successful in their attempts to produce new flowers

or new varieties of vegetables by seminal or graft-hybrids, and any florist's catalogue or the account of any special plant, such as is to be found in Foster-Melliar's *Book of the Rose*, is in great part a history of successful hybridization. Much special experimental work has been done by botanists, notably by de Vries, to the result of whose experiments we shall recur. Experiments show clearly that the obtaining of hybrids is in many cases merely a matter of taking sufficient trouble, and the successful crossing of genera is not infrequent.

Focke, for instance, cites cases where hybrids were obtained between *Brassica* and *Raphanus*, *Galium* and *Asperula*, *Campanula* and *Phyteuma*, *Verbascum* and *Celsia*. Among animals, new records and new experiments are almost equally numerous. Boveri has crossed *Echinus microtuberculatus* with *Sphærechinus granularis*. Morgan even obtained hybrids between *Asterias*, a Starfish, and *Arbacia*, a Sea-urchin, a cross as remote as would be that between a fish and a mammal. Vernon got many hybrids by fertilizing the eggs of *Strongylocentrotus lividus* with the sperm of *Sphærechinus granularis*. Standfuss has carried on an enormous series of experiments with Lepidopterous insects, and has obtained a very large series of hybrids, of which he has kept careful record. Lepidopterists generally begin to suspect that many curious forms offered by dealers as new species are products got by crossing known species. Apellö has succeeded with Teleostean fish; Gebhardt and others with Amphibia. Elliot and Suchetet have studied carefully the question of hybridization occurring normally among birds, and have got together a very large body of evidence. Among the cases cited by Elliot the most striking are that of the hybrid between *Colaptes cafer* and *C. auratus*, which occurs over a very wide area of North America and is known as *C. hybridus*, and the hybrid between *Euplocamus lineatus* and *E. horsfieldi*, which appears to be common in Assam. Among Mammals the most noteworthy results have been obtained by Professor Cossar Ewart, who has bred nine zebra hybrids by crossing mares of various sizes with a zebra stallion, and who has studied in addition three hybrids out of zebra mares, one sired by a donkey, the others by ponies.

The causes militating against the production of hybrids have also received considerable attention. Delage, discussing the question, states that there is a general proportion between sexual attraction and zoological affinity, and in many cases hybrids are not naturally produced simply from absence of the stimulus to sexual mating, or because of preferential mating within the species or variety. In addition to differences of habit, temperament, time of maturity, and so forth, gross structural differences may make mating impossible. Thus Escherick contends that among insects the peculiar structure of the genital appendages makes cross-impregnation impossible, and there is reason to believe that the specific peculiarities of the modified sexual palps in male spiders have a similar result.

The difficulties, however, may not exist, or may be overcome by experiment, and frequently it is only careful management that is required to produce crossing. Thus it has been found that when the pollen of one species does not succeed in fertilizing the ovules of another species, yet the reciprocal cross may be successful; that is to say, the pollen of the second species may fertilize the ovules of the first. Vernon, working with Sea-urchins, found that the obtaining of hybrids depended on the relative maturity of the sexual products. The difficulties in crossing apparently may extend to the chemiotaxic processes of the actual sexual cells. Thus when the spermatozoa of an Urchin were placed in a drop of sea-water containing ripe eggs of an Urchin and of a Starfish, the former eggs became surrounded by clusters of the male cells, while the latter appeared to exert little attraction for the alien germ-cells. Finally, when the actual impregnation of the egg is possible naturally, or has been secured by artificial means, the development of the hybrid may stop at an early stage. Thus hybrids between the Urchin and the Starfish, animals belonging to different classes, reached only the stage of the pluteus larva. Apellö, experimenting with Teleostean fish, found that very often impregnation and segmentation occurred, but that the development broke down immediately afterwards. Gebhardt, crossing *Rana esculenta* with *R. arvalis*, found that the cleavage of the ovum was normal, but that abnormality began with the gastrula, and that development soon stopped. In a very general fashion there appears to be a parallel between the zoological affinity and the extent to which the incomplete development of the hybrid proceeds.

As to the sterility of hybrids *inter se*, or with either of the parent forms, information is still wanted. Delage, summing up the evidence in a general way, states that mongrels are more fertile and stronger than their parents, while hybrids are at least equally hardy but less fertile. While many of the hybrid products of horticulturists are certainly infertile, others appear to be indefinitely fertile.

Focke, it is true, states that the hybrids between *Primula auricula* and *P. hirsuta* are fertile for many generations, but not indefinitely so; but, while this may be true for the particular case, there seems no reason to doubt that many plant hybrids are quite fertile. In the case of animals the evidence is rather against fertility. Standfuss, who has made experiments lasting over many years, and who has dealt with many genera of Lepidoptera, obtained no fertile hybrid females, although he found that hybrid males paired readily and successfully with pure-bred females of the parent races. Elliot, dealing with birds, concluded that no hybrids were fertile with one another beyond the second generation, but thought that they were fertile with members of the parent races. Wallace, on the other hand, cites from Quatrefages the case of hybrids between the moths *Bombyx cynthia* and *B. arrindia*, which were stated to be fertile *inter se* for eight generations. He also states that hybrids between the sheep and goat have a limited fertility *inter se*. Cornevin and Lesbre state that in 1873 an Arab mule was fertilized in Africa by a stallion, and gave birth to female offspring which she suckled. All three were brought to the Jardin d'Acclimatation in Paris, and there the mule had a second female colt to the same father, and subsequently two male colts in succession to an ass and to a stallion. The female progeny were fertilized, but their offspring were feeble and died at birth. Cossar Ewart gives an account of a recent Indian case in which a female mule gave birth to a male colt. He points out, however, that many mistakes have been made about the breeding of hybrids, and is not altogether inclined to accept this supposed case. Very little has been published with regard to the most important question, as to the actual condition of the sexual organs and cells in hybrids. There does not appear to be gross anatomical defect to account for the infertility of hybrids, but microscopical examination in a large number of cases is wanted. Cossar Ewart, to whom indeed much of the most interesting recent work on hybrids is due, states that in male zebra-hybrids the sexual cells were immature, the tails of the spermatozoa being much shorter than those of the similar cells in stallions and zebras. He adds, however, that the male hybrids he examined were young, and might not have been sexually mature. He examined microscopically the ovary of a female zebra-hybrid and found one large and several small Graafian follicles, in all respects similar to those in a normal mare or female zebra. A careful study of the sexual organs in animal and plant hybrids is very much to be desired, but it may be said that so far as our present knowledge goes there is not to be expected any obvious microscopical cause of the relative infertility of hybrids.

The relative variability of hybrids has received considerable attention from many writers. Horticulturists, as Bateson has written, are "aware of the great and striking variations which occur in so many orders of plants when hybridization is effected." The phrase has been used "breaking the constitution of a plant" to indicate the effect produced in the offspring of a hybrid union, and the device is frequently used by those who are seeking for novelties to introduce on the market. It may be said generally that hybrids are variable, and that the products of hybrids are still more variable. Delage states that in reciprocal crosses there is always a marked tendency for the offspring to resemble the male parents; he quotes from Huxley that the mule, whose male parent is an ass, is more like the ass, and that the hinny, whose male parent is a horse, is more like the horse. Standfuss found among Lepidoptera that males were produced much more often than females, and that these males paired readily. The freshly-hatched larvæ closely resembled the larvæ of the female parent, but in the course of growth the resemblance to the male increased, the extent of the final approximation to the male depending on the relative phylogenetic age of the two parents, the parent of the older species being prepotent. In reciprocal pairing, he found that the male was able to transmit the characters of the parent in a higher degree. Cossar Ewart, in

relation to zebra hybrids, has discussed the matter of resemblance to parents in very great detail, and fuller information must be sought in his writings. He shows that the wild parent is not necessarily prepotent, although many writers have urged that view. He described three hybrids bred out of a zebra mare by different horses, and found in all cases that the resemblance to the male or horse parent was more profound. Similarly, zebra-donkey hybrids out of zebra mares bred in France and in Australia were in characters and disposition far more like the donkey parents. The results which he obtained in the hybrids which he bred from a zebra stallion and different mothers were more variable, but there was rather a balance in favour of zebra disposition and against zebra shape and marking.

"Of the nine zebra-horse hybrids I have bred," he says, "only two in their make and disposition take decidedly after the wild parent. As explained fully below, all the hybrids differ profoundly in the plan of their markings from the zebra, while in their ground colour they take after their respective dams or the ancestors of their dams far more than after the zebra—the hybrid out of the yellow and white Iceland pony, *e.g.*, instead of being light in colour, as I anticipated, is for the most part of a dark dun colour, with but indistinct stripes. The hoofs, mane, and tail of the hybrids are at the most intermediate, but this is perhaps partly owing to reversion towards the ancestors of these respective dams. In their disposition and habits they all undoubtedly agree more with the wild sire."

Ewart's experiments and his discussion of them also throw important light on the general relation of hybrids to their parents. He found that the colouration and pattern of his zebra hybrids resembled far more those of the Somali or Grévy's zebra than those of their sire —a Burchell's zebra. In a general discussion of the stripings of horses, asses, and zebras, he came to the conclusion that the Somali zebra represented the older type, and that therefore his zebra hybrids furnished important evidence of the effect of crossing in producing reversion to ancestral type. The same subject has of course been discussed at length by Darwin, in relation to the cross-breeding of varieties of pigeons.

Other writers, in particular Weismann, Bateson, and de Vries, have discussed the phenomena of hybridism for their bearing on the general questions of inheritance, and of the nature of characters and of variations. Gaertner and Naegeli had declared that the farther apart the parents, the more definite and intermediate the hybrids; the nearer the parents, the more variable the hybrids. Weismann concludes, from examination of a series of plant hybrids, that, from the same cross, hybrids of different character may be obtained, but that the characters are determined at the moment of fertilization; for he found that all the flowers on the same hybrid plant resembled one another in the minutest details of colour and pattern. Bateson approaches the subject chiefly as a means of studying the nature of variations, and has found a series of important pieces of evidence that variations of large magnitude (discontinuous variation) are produced by hybridization. He cites in this connexion the cases of narcissus, begonia, pelargonium, gladiolus, streptocarpus, a great number of orchids, rhododendron, cineraria, and others. Miss Saunders, working in association with him, has found three important cases of discontinuity in hybrid offspring. Bateson urges forcibly the necessity of detailed observation and experiment in this direction, and particularly insists on the necessity of rearing and noting the characters of all the seedlings obtained from hybridization. Horticulturists for the most part have been content to pick out the most striking forms and to keep no record of the others. De Vries has obtained results of very great interest, and has formulated from them what he calls the "Law of disjunction of hybrids." He supposes specific characters to be distinct units (or composed of distinct units), and finds the best mode of studying them in cases where species are distinguished by a single character. Hybrids are described vaguely as mingling the characters of father and mother. What really happens, he thinks, is that they have in a simple form some of the characters of each. When father and mother are distinguished by one character, this cannot happen; such a *monohybrid* never shows the character of one parent (absent in the other) in a reduced form; it possesses it, or it does not possess it. He found on sowing seeds of monohybrids that always about 25 per cent. of the seedlings showed one character (the latent, or recessive character), while 75 showed the other (dominant character). On sowing the seeds of these latter, self-fertilized and kept separate in plots, 25 of them gave the dominant character pure, the others were mixed in the proportion of 37·5 with the dominant to 12·5 with the recessive character. Thus he crossed poppies with a black spot on base of petals (B) with poppies with a white spot (W). On sowing the seeds of these hybrids 75 per cent. were B (dominant) and 25 were W (latent). On sowing the seeds of the 75 B's, 25 gave pure B's, while the others gave mixed results in the proportion of 37·5 B to 12·5 W. The second sowing was needed to distinguish among the 75 B's the 25 which, like the 25 W's, were not hybrids, but had inherited similarly from father and mother. He thinks that all hybrids when studied with reference to single characters will give similar results. The interesting experiments and conclusions of de Vries appear to be strictly derivative from older work published by Gregor Mendel in 1865. The law of the disjunction of unit characters in hybrids, including the distinction between *dominant* and *recessive*, and the numerical distribution of these, must be called Mendel's Law. Much experimental work is required to elaborate it, but it appears to be a fundamental principle of biology, and it is a curious circumstance that such a principle, as striking as the law of combining proportions in chemistry, should have remained unnoticed for so many years after it had been clearly formulated and supported by abundant experimental evidence.

(P. C. M.)

Hyde, a municipal borough (1881), railway station, and market town, in the Hyde parliamentary division of Cheshire, England, 4 miles north-east of Stockport. Recent erections include the town-hall (1885), the public baths (1887), new technical school and free library (1899), and new post office (1900). Area, 3072 acres. Population (1881), 28,630; (1901), 32,768.

Hyde Park, a town of Norfolk county, Massachusetts, U.S.A. It lies immediately south-west of Boston, of which it is a residential suburb, on the New England and the New York, New Haven and Hartford Railways. Population (1880), 7088; (1890), 10,193; (1900), 13,244, of whom 3805 were foreign-born and 116 were negroes.

Hydraulic Power. See Power Transmission (*Hydraulic*).

Hydrophobia.—Two new points of interest have arisen in connexion with this rare disease. One is the Pasteur treatment by inoculation with rabic virus, and the other was the attempt of the Government to exterminate rabies in the British Isles by muzzling dogs. The Pasteur treatment was first applied to human beings in 1885 after prolonged investigation and experimental trial on animals. It is based on the fact that a virus, capable of giving rabies by inoculation, can be extracted from the tissues of a rabid animal and then intensified or attenuated at pleasure. It appears that the strength of the rabic virus, as determined by inoculation, is constant in the same species of animal, but is modified by passing through another species. For instance, the natural virus of dogs is always of the same strength, but when inoculated into monkeys it becomes weakened, and the process of attenuation can be carried on by passing the virus through a succession of monkeys, until it loses the power of causing death. If this weakened virus is then passed back through guinea-pigs, dogs, or rabbits, it regains its former strength. Again, if it be passed through a succession of dogs it becomes intensified up to a maximum of strength, which is called the *virus fixe*. Pasteur further discovered that the strength can be modified by temperature and by keeping the dried tissues of a rabid animal containing the virus. Thus, if the spinal cord of a rabid dog be preserved in a dry state, the virus loses strength day by day. The system of treatment consists in making an emulsion of the cord and graduating the strength of the dose by using a succession of cords, which have been kept for a progressively diminishing length of time. Those which have been kept for fourteen days are used as a starting-point, yielding virus of a minimum strength. They are followed by preparations of diminishing age and increasing strength, day by day, up to the maximum, which is three days old. These are successively injected into the circulatory system. The principle is the artificial acquisition by the patient of resistance to the rabic virus, which is presumed to be already in the system, but has not yet become active, by accustoming him gradually to its toxic effect, beginning with a weak form and progressively increasing the dose. It is not exactly treatment of the disease, because it is useless or nearly so when the disease has commenced, nor is it exactly preventive, for the patient has already been bitten. It must be regarded as a kind of anticipatory cure. The cords are cut into sections and preserved dry in sterilized flasks plugged with cotton-wool. Another method of preparing the inoculatory virus, which has been devised by Tizzani and Centanni, consists in subjecting the *virus fixe* to peptic digestion by diluted gastric juice for varying periods of time.

The first patient was treated by Pasteur's system in July 1885. He was successively inoculated with emulsions made from cords that had been kept fourteen and ten days, then eleven and eight days, then eight, seven, six days, and so on. Two forms of treatment are now used—(1) the "simple," in which the course from weak to strong virus is extended over nine days; (2) the "intensive," in which the maximum is reached in seven days. The latter is used in cases of very bad bites and those of some standing, in which it is desirable to lose no time. Two days are compressed into one at the commencement by making injections morning and evening instead of once a day, so that the fifth-day cord is reached in four days instead of six, as in the "simple" treatment. When the maximum—the third-day cord—is reached the injections are continued with fifth-, fourth-, and third-day cords. The whole course is fifteen days in the simple treatment and twenty-one in the intensive. The doses injected range from 1 to 3 cubic centimetres. Injections are made alternately into the right and left flanks. The number treated in each year since 1885, with the mortality, is given in the following table:—

Year.	Patients Treated.	Deaths.	Mortality per cent.
1886	2671	25	·94
1887	1770	14	·79
1888	1622	9	·55
1889	1830	7	·38
1890	1540	5	·32
1891	1559	4	·25
1892	1790	4	·22
1893	1648	6	·36
1894	1387	7	·50
1895	1520	5	·33
1896	1308	4	·30
1897	1521	6	·39
1898	1465	3	·20
1899	1614	4	·25

These figures do not include cases which develop hydrophobia during treatment or within fifteen days after treatment is completed, for it is held that persons who die within that period have their nervous centres invaded by virus before the cure has time to act. The true mortality should therefore be considerably higher. For instance, in 1898 three deaths came within this category, which just doubles the mortality; and in 1899 the additional deaths were six, bringing the mortality up to two and a half times that indicated in the table. When, however, the additional deaths are included the results remain sufficiently striking, if two assumptions are granted—(1) that all the persons treated have been bitten by rabid animals; (2) that a large proportion of persons so bitten usually have hydrophobia. Unfortunately, both these assumptions lack proof, and therefore the evidence of the efficacy of the treatment cannot be said to satisfy a strictly scientific standard. With regard to the first point, the patients are divided into three categories—(1) those bitten by an animal the rabidity of which is proved by the development of rabies in other animals bitten by it or inoculated from its spinal cord; (2) those bitten by an animal pronounced rabid on a veterinary examination; (3) those bitten by an animal suspected of being rabid. The number of patients in each category in 1898 was (1) 141, (2) 855, (3) 469; and in 1899 it was (1) 152, (2) 1099, (3) 363. As might be expected, the vast majority come under the second and third heads, in which the evidence of rabidity is doubtful or altogether lacking. With regard to the second point, the proportion of persons bitten by rabid animals who ordinarily develop hydrophobia has only been "estimated" from very inadequate data; but if the number of rabid dogs be compared with the deaths from hydrophobia in any year or series of years, it can hardly be very high. For instance, in 1895, 668 dogs, besides other animals, were killed and certified to be rabid in England, and the deaths from hydrophobia were twenty. Of course this proves nothing, as the number of persons bitten is not known, but the difference between the amount of rabies and of hydrophobia is suggestively great in view of

the marked propensity of rabid dogs to bite, nor is it accounted for by the fact that some of the persons bitten were treated at the Institut Pasteur. A comparison of the annual mortality from hydrophobia in France before and after the introduction of the treatment would afford decisive evidence as to its efficacy; but unfortunately no such comparison can be made for lack of vital statistics in that country. The experience of the Paris hospitals, however, points to a decided diminution of mortality. On the whole it must be said, in the absence of further data, that while the Pasteur treatment probably diminishes the danger of hydrophobia from the bites of rabid animals, the extent to which it does so is at present uncertain.

Some attempt has been made to argue that the treatment is itself dangerous, and that persons have died from it, not from the bites they had received. Colour was given to the suggestion by the case of a man named O'Leary, who was bitten in the right leg by a dog at Lahore on 22nd August 1898. He was treated at the Institut Pasteur from 12th September to 26th October, and died of hydrophobia in India on 22nd November. The dog could not be traced, but it bit another dog which remained quite well; and the inference was drawn that the first dog was not rabid at all. The facts are not sufficiently explicit to warrant the conclusion that the man died from the effects of the treatment; and even if he did, it is clear, from the very large number of persons treated year by year with good results, that any risk there may be is very small. More recently treatment with an anti-rabic serum has been suggested.

The attempt to stamp out rabies in Great Britain was an experiment undertaken by the Government in the public interest. The principal means adopted were the muzzling of dogs in infected areas, and prolonged quarantine for imported animals. The efficacy of dog-muzzling in checking the spread of rabies and diminishing its prevalence has been repeatedly proved in various countries. It is probable that all carnivorous animals are subject to rabies, and its occurrence in wolves, cats, and foxes is common. Horses, cows, sheep, pigs, and deer have also been known to take it, but in England at least the dog is preëminently the vehicle of contagion and the great source of danger to human beings. There is a difference of opinion on the way in which muzzling acts, though there can be none as to the effect it produces in reducing rabies. Probably it acts rather by securing the destruction of ownerless and stray—which generally includes rabid—dogs than by preventing biting; for though it may prevent snapping, even the wire-cage muzzle does not prevent furious dogs from biting, and it is healthy, not rabid, dogs that wear the muzzle. It has therefore been suggested that a collar would have the same effect, if all collarless dogs were seized; but the evidence goes to show that it has not, perhaps because rabid dogs are more likely to stray from home with their collars, which are constantly worn, than with muzzles which are not, and so escape seizure. Moreover, it is much easier for the police to see whether a dog is wearing a muzzle or not than it is to make sure about the collar. However this may be, the muzzle has proved more efficacious, but it was not applied systematically in England until a late date. Sometimes the regulations were in the hands of the Government, and sometimes they were left to local authorities; in either case they were allowed to lapse as soon as rabies had died down. In April 1897 the Board of Agriculture entered on a systematic attempt to exterminate rabies by the means indicated. The plan was to enforce muzzling over large areas in which the disease existed, and to maintain it for six months after the occurrence of the last case. In spite of much opposition and criticism, this was resolutely carried out, and met with great success. By the spring of 1899—that is, in two years—the disease had disappeared in Great Britain, except for one area in Wales; and with this exception, muzzling was everywhere relaxed in October 1899. It was taken off in Wales also in the following May, no case having occurred since November 1899. Rabies was then pronounced extinct. During the summer of 1900, however, it reappeared in Wales, and several counties were again placed under the order. In December 1901 the United Kingdom was declared free from rabies, and all restrictions, save quarantine for dogs imported from abroad, were removed. According to the Government theory, the disease should never reappear, but the hope is hardly justified by present knowledge. The history of rabies shows that it is endemic in Britain and other populous countries, while in some it is wholly unknown, and that from time to time it assumes epidemic proportions and then dies down again quite independently of muzzling or any such measure. Judging by analogy, we should rather regard it as a disease which is spread by contagion, but does not depend for its existence on contagion, as it may remain latent, becoming active periodically under favourable conditions. The assumption that it exists only in the persons of rabid dogs is highly improbable, and cannot be accepted on the evidence available. We may expect, therefore, that it will reappear from time to time with greater or less diffusive force, but that the measures adopted will be efficacious in checking its spread and keeping it down to insignificant proportions when it does appear. In other words, experience justifies the hope that hydrophobia may be abolished in Great Britain, whether rabies is "stamped out" or not.

Hyères, a winter health resort, arrondissement of Toulon, department of Var, France, 11 miles east of Toulon by rail. Numerous villas have been erected in recent years on the beach, about two miles from the town. Port Pothuau, so named in 1881, is the port of the Salins d'Hyères. The salins yield annually about 20,000 tons of salt. Flowers and fruits are extensively cultivated for the London and Paris markets, and cork-cutting is a considerable industry. Strawberries alone are said to be exported to the value of £20,000 annually. In 1899, 209 vessels of 27,741 tons entered and cleared from Port Pothuau, almost entirely engaged in coasting trade. Population (1881), 5918; (1891), 8292; (1901), 17,659.

Hygiene.—The science of practical hygiene aims at "rendering growth more perfect, decay less rapid, life more vigorous, death more remote." The subject involves an acquaintance with such diverse sciences as physics, chemistry, geology, engineering, architecture, meteorology, epidemiology, bacteriology, and statistics. To these may be added the study of the law or those legal enactments which concern the sanitary well-being of the community. In this article it is proposed to refer only to the more important questions in respect to which recent scientific research has led to a better conception of the cause of diseases and methods for their prevention.

The influence of different kinds of soil as a factor in the production of disease requires to be considered, in regard not only to the nature and number of the micro-organisms they contain, but also to the amount of moisture and air in them and their capacity for heat. The moisture in soil is derived from two sources—the rain and the ground water. Above the level of the ground water the soil is kept moist

by capillary attraction and by evaporation of the water below, by rainfall and by movements of the ground water; on the other hand, the upper layers are constantly losing moisture by evaporation from the surface and through vegetation. When the ground water rises it forces air out of the soil; when it falls again it leaves the soil moist and full of air. The nature of the soil will largely influence the amount of moisture which it will take up or retain. In regard to water all soils have two actions, namely, permeability and absorbability. Permeability is practically identical with the speed at which percolation takes place; through clay it is slow, but increases in rapidity through marls, loams, limestones, chalks, coarse gravels, and fine sands, reaching a maximum in soil saturated with moisture. The amount of moisture retained depends mainly upon the absorbability of the soil, and as it depends largely on capillary action, it varies with the coarseness or fineness of the pores of the soil, being greater for soils which consist of fine particles. The results of many analyses show that the capacity of soils for moisture increases with the amount of organic substances present: decomposition appears to be most active when the moisture is about 4 per cent., but can continue when it is as low as 2 per cent., while it appears to be retarded by any excess over 4 per cent. Above the level of the ground water all soils contain air, varying in amount with the degree of looseness of the soil. Some sands contain as much as 50 per cent. of air of nearly the same composition as atmospheric air. The oxygen, however, decreases with the depth, while the carbon dioxide increases.

Soil and disease.

Among the most noteworthy workers at the problems involved in the question of the influence of soil in the production of disease, we find von Foder, Pettenkofer, Levy, Fleck, von Naegeli, Schleesing, Muntz, and Warrington. The study of epidemic and endemic diseases generally has brought to light an array of facts which very strongly suggest that an intimate association exists between the soil and the appearance and propagation of certain diseases; but although experiments and observations allow this view to be looked upon as well established, still the precise *rôle* played by the soil in an ætiological respect is by no means so well understood as to make it possible to separate the factors and dogmatize on their effects. The earliest writers upon cholera emphasized its remarkable preference for particular places; and the history of each successive epidemic implies, besides an importation of the contagion, certain local conditions which may be either general sanitary defects or peculiarities of climate and soil. The general evidence indicates that the specific bacteria of cholera discharges are capable of a much longer existence in the superficial soil layers than has hitherto been supposed; consequently, it is specially necessary to guard against pollution of the soil, and through it against the probable contamination of both water and air. The evidence, however, is not sufficiently strong to warrant a universal conclusion, the diffusion of cholera appearing to be largely dependent upon other factors than soil states. Again, all accounts of diphtheria show a tendency on the part of the disease to recur in the same districts year after year. The questions naturally suggest themselves—Are the reappearances due to a revival of the contagion derived from previous outbreaks in the same place, or to some favouring condition which the place offers for the development of infection derived from some other quarter; and have favouring conditions any dependence upon the character and state of the soil? Greenhow in 1858 stated that diphtheria was especially prevalent on cold, wet soils; and Airy in 1881 describes the localities affected as "for the most part cold, wet clay lands." An analysis of the innumerable outbreaks in various parts of Europe indicates that the geological features of the affected districts play a less important part in the incidence of the disease than soil dampness. In this connexion it is interesting to note the behaviour of the diphtheritic contagion in soil. We have no actual proof that the bacillus is either an ordinary or an occasional resident of the soil, or that it becomes air-borne in sewer-gas or soil emanations. But experiments show that pure cultures, when mixed with garden soil constantly moistened short of saturation, and kept in the dark at a temperature of 14° C., will retain their vitality for more than ten months; from moist soil kept at 26° C. they die out in about two months; from moist soil at 30° C., in seventeen days; and in dry soil at the same temperature, within a week. In the laboratory absolute soil dryness is as distinctly antagonistic to the vitality of the diphtheria bacillus as soil dampness is favourable. Both statistically and experimentally we find that a damp soil favours its life and development, while prolonged submersion and drought kill it. We may consider that, in country districts, constant soil moisture is one of the chief factors; while in the case of urban outbreaks mere soil moisture is subsidiary to other more potent causes.

Again, many facts in the occurrence and diffusion of enteric fever point to an intimate connexion between its origin and certain conditions of locality. Epidemics rarely spread over any considerable tract of country, but are nearly always confined within local limits. Observations made at the most diverse parts of the globe, and the general distribution area of the disease, show that mere questions of elevation or even configuration of the ground have little or no influence. On the other hand, the same observations go to show that the disease is met with oftener on the more recent formations than the older, and this fact, so far as concerns the physical characters of the soil, is identical with the questions of permeability to air and water. Robertson has shown that the typhoid bacillus can grow very easily in certain soils, can persist in soils through the winter months, and when the soil is artificially fed, as may be done by a leaky drain, or by access of filthy water from the surface, the micro-organism will take on a fresh growth in the warm season. The destructive power of sunlight is only exercised on those organisms actually at the surface. Cultures of the typhoid organism planted at a depth of 18 inches were found to have grown to the surface. In the winter months the deeper layers of the soil act as a shelter to the organism, which again grows towards the surface during the summer. The typhoid organism was not found to be taken off from the decomposing masses of semi-liquid filth largely contaminated with a culture of *bacillus typhosus;* but, on the other hand, it was abundantly proved that it could grow over moist surfaces of stones, &c. Certain disease-producing organisms, such as the bacillus of tetanus and malignant œdema, appear to be universally distributed in soil, while others, as the *bacillus typhosus* and *spirillum choleræ*, appear to have only a local distribution. The conditions which favour the vitality, growth, and multiplication of the typhoid bacillus are the following:—The soil should be pervious; it should be permeated with a sufficiency of decaying—preferably animal—organic matters; it should possess a certain amount of moisture, and be subject to a certain temperature. Depriving the organism of any of these essential conditions for its existence in the soil will secure our best weapon for defence. The optimum temperature adapted to its growth and extension is 37° C. = 98°·4 F. Sir Charles Cameron attributes the prevalence of typhoid in certain areas in Dublin to the soil becoming saturated with fæcal matter and specifically infected. The ratio of cases to population living in Dublin on loose porous gravel soil for the ten years 1881–91 was 1 in 94, while that of those living on stiff clay soil was but 1 in 145. "This is as we should expect, since the movements of ground air are much greater in loose porous soils than in stiff clay soils." A foul gravel soil is a most dangerous one on which to build. For warmth, for dryness, for absence of fog, and for facility of walking after rain, just when the air is at its purest and its best, there is nothing equal to gravel; but when gravel has been rendered foul by infiltration with organic matters it may easily become a very hot-bed of disease.

Sewage.

The first practical attempt to purify sewage by a biological process was made by Scott Moncrieff in Great Britain in 1891. The State Board of Health of Massachusetts had previously made a series of experiments upon downward filtration, which showed that the same process that occurred in soils could be carried on in artificial filters. The biological treatment of sewage may be conveniently divided into two stages: (1) the breaking down or liquefying of the organic matter; (2) the nitrifying of the results of the first stage. The changes produced in these stages are effected by means of micro-organisms existing either in the sewage to be treated or in its surroundings. Both aërobic and anaërobic organisms share in the work of breaking down the organic matter, but the former alone are capable of producing nitrification. Scott Moncrieff's system consists of allowing the sewage to enter from below a tank, filled with stones, sufficiently slowly to be acted upon by the anaërobic organisms which form dense colonies in the nidus formed by the stones: the result being that the solid organic matter is liquefied, and a liquid free from suspended matters passes on. The nitrifying chamber is filled with a series of trays containing filtering media, placed one above the other,

with intervening spaces of a few inches between them. The liquid passes slowly downwards through the various trays, meeting under favourable conditions aërobic micro-organisms, and finally passes away to the stream or outfall.

In the "Sutton" system the sewage, after rough straining, is run on to coarse-grain filter beds of burnt ballast, the outlet of each of which is closed in turn and the bed rapidly filled up; the sewage is allowed to remain for about an hour, when it is quickly drawn off and passed on to fine-grain filters as a second or completing stage. The object of the coarse-grain filter bed is to admit the particles of suspended matter contained in the crude sewage into the interior of the bed, where they are subjected to the action of the anaerobic organisms. If the first bed were made of fine material the suspended matter would collect on the surface and have to be dealt with at frequent intervals, and in this case the problem of sludge disposal would again arise. The size of filter material which Dibden has found most suitable is, in the case of a coarse bed, that which will pass through a two-inch ring and be totally rejected by a screen having a half-inch mesh; and, for a fine bed, that which will pass a screen of three-eighths or quarter-inch mesh, and be rejected by one having a mesh of one-sixteenth of an inch.

The "septic tank-system" was devised by Cameron of Exeter in 1896. It consists in providing (1) a closed chamber or tank through which the sewage passes and in which the organic matters in the sewage are brought into solution by anaërobic organisms, and (2) a series of filters worked on the "Sutton" principle, *i.e.*, filling, remaining full, emptying, and resting. The septic tank is constructed to hold about one day's average flow, so that the sewage takes twenty-four hours to pass through it. The flow through the tank is continuous, and the effluent passes off at the same level as the sewage passes in, *i.e.*, to a depth of about 5 feet below the surface. The object is to avoid disturbance of the scum which forms on the surface of the fluid in the tank, and also to prevent the passage of air with the sewage and the reflux of gases from the tank into the sewers. The deposit which forms on the bottom of the tank consists of road grit, together with the insoluble residue from the decomposition of the sewage solids, and is made up of about 8 per cent. of mineral matter, 4 per cent. of organic matter, and 88 per cent. water. The clear water, which forms between the scum on the surface and the deposit at the bottom of the tank, passes out through a cast-iron pipe fifteen inches below the surface of the scum to distributing wells. In these wells valves are placed which control the flow to the distributing channels on the surface of the filters. Each filter is filled to a depth of 4½ feet with crushed furnace clinker resting on 6 inches of coarse gravel. The filters are filled and discharged automatically by means of alternating gear. The bacteriology of the septic-tank process has been investigated by Sims Woodhead, who found that the crude sewage contained the largest number of anaërobic organisms; fluorescing and gas-producing varieties were also numerous. In the septic tank the number of anaërobic organisms did not appear to increase, but the varieties which rapidly liquefied gelatine were found in greater numbers than in crude sewage. In the tank effluent and the filtrate from the beds the number of liquefying anaërobic organisms was found to have fallen considerably. As regards aërobic organisms, the liquefying varieties were in greatest number in the crude sewage and tank contents. Non-liquefying organisms were also present in greater numbers than after the sewage had passed the filters. The organisms in the filter beds are chiefly aërobic, but the anaërobic species which have made their way from the septic tank are undoubtedly present, ready to commence work whenever the conditions become favourable. This system gives excellent results and has already been largely adopted.

At Manchester very successful experiments have been made with an *open septic tank and double filtration* in bacterial filter beds. Raw sewage is allowed to run from the main sewer through a large open tank. "The contents of the tank soon became black, and bubbles of gas began to rise, often accompanied by masses of sludge from the bottom, on still days forming a scum, which gradually completely covered the surface of the liquid." The gas evolved was found to be largely composed of marsh gas, showing that resolution of organic matter was taking place. Nine months after the open tank was placed in operation a flow of 2,500,000 gallons was allowed to pass through in twenty-four hours. About the same time garbage collected from the mechanical screens at the entrance to the works was tipped into the tanks, and a gradual disintegration of the garbage ensued. The effluent from the open septic tank is then treated by double contact on bacteria beds. In every case the effluent from the second filter bed was found non-putrescible.

An important point in connexion with the biological process is that, by the adoption of it, sludge may be looked upon as a practically negligible quantity. The small amount of road grit and other mineral matter mixed up with sewage can easily be eliminated by ordinary grit chambers provided in front of the installation. It may safely be said that the average results by the biological treatment are quite as good as those given by well-managed sewage farms, while the best results are far beyond them.

Water filtration.

Boiling is perhaps the oldest method in practice for the purification of water. The objection to this procedure is that the dissolved gases are driven off, and unless the water is again aërated during the process of cooling it will be found flat and insipid to taste. Special sterilizers have been introduced in order to overcome this difficulty. The best machines are those invented by Desmaroux, Maiche, and Waterhouse-Forbes. In all these machines there is the same principle—an exchange heater by means of which the incoming cold water receives heat from the outgoing hot water, and in this way the fuel required to raise the water to the required temperature is much lessened and the effluent from the machine is almost as cold as the supply.

In Desmaroux's machine the water retains its gases and is quite cool at the exit. The machine is arranged to work at any temperature between 100° C and 120° C. The requisite head to cause the water to pass through the apparatus is obtained by means of a pump, when pressure from a public supply is not available. Maiche's apparatus is also provided with a boiler, exchange heater, and pressure regulators. The water is heated to 109° C. for four minutes, and is delivered from the exchange heater as cool sterile water ready for use. The apparatus delivers about 22 gallons per hour at an expenditure of 6 cubic feet of gas. In the Waterhouse-Forbes sterilizer the water is only boiled for a few seconds, and it is claimed for it that the dissolved gases are not driven off. An apparatus weighing 25 ℔ is capable of delivering 5 gallons of sterilized water per hour. Careful experiments showed that when rich emulsions of *B. coli* or *B. prodigenus* were passed through these machines not a single organism could be detected in the sterilized water.

The addition of bromine to water has been suggested by Dr Pehlumberg. Experiments have proved that 0·06 gramme of bromine per litre, after five minutes' exposure, will render most surface waters safe for drinking purposes. The colour and taste of the bromine are readily removed after the five minutes' treatment by adding 0·095 gramme of sodium hyposulphite and 0·04 gramme of anhydrous sodium carbonate to each litre of water.

Peiftee was the first to show that sand alone could not remove micro-organisms from water. Filters made of sterilized sand were found actually to increase the number of bacteria during the first few days of working, but with the formation of a slimy layer on the surface and in the body of the filter bed the true filtering action commenced. This slimy layer, to which the greatest importance is now attached, consists of zoogloea of bacteria, combined with suspended materials in the water. It is very friable and readily broken up by excessive pressure on the surface or disturbance of the body of the filter beds. Hence the extreme care now taken to fill the filter beds from below, so as to prevent the zoogloea masses from being broken up by the pressure of the air and to control the rate of filtration and limit the pressure of water on the surface. The degree of fineness of the sand grains is also of importance in securing a good filtrate. Hence the work of a filter bed is partly mechanical and partly vital. By the growth of bacteria in the bed, food material is used up and the products of bacterial life are eliminated, so that the growth of bacteria through the filter is arrested. But a sand filter will not arrest all the micro-organisms contained in a water applied to the surface, nor can it give absolute protection against water-borne disease: if the rate of filtration is properly controlled it can give such a protection that in practice we have every reason to be satisfied with it (Koch). Reservoirs to store filtered water should always be covered, so as to avoid contamination with dust, &c.

The sterilization of water by ozone has been proposed by Ohmuller, Suidal, and other workers. In 1898 Marinier and Abraham devised an apparatus for the treatment on a large scale of water supplied to the town of Lille. When the water is treated with ozone, equal to 6 mgms. per litre of air, all pathogenic and saprophytic microbes are destroyed. The ozone treatment increases the aëration of the water and diminishes the organic matter: the nitrates are unaffected. Weyl of Berlin has also reported very favourably on the ozone treatment established at the waterworks at Charlottenburg: the results obtained were the same as those met with when water is purified by careful sand filtration.

The principal methods for effecting the preservation of foods are by (a) drying, (b) smoking, (c) salting, (d) sugar and vinegar, (e) exclusion of air, (f) cold, (g) mineral or organic antiseptics. The preservation of milk is exceedingly difficult, because the liquid is particularly liable to infection by hardy germs. Even when yielded by a healthy cow, the milk on issuing from the udder is already infested with bacteria. When milking is ended, a small quantity of milk is left behind in the lacteal ducts, and in it there settle a number of bacteria, which, making their way from the outside, are favoured by a high temperature and become incorporated with the subsequent flow of milk. In addition to these there are innumerable bacteria originating in the dung and adhering to the udder. The air in the cowhouse is laden with germs, and yields up no small quantities of these to the milk. The germs present in freshly-drawn milk increase very rapidly during transit to the centres of consumption, as also during storage in milk-shops. The reproduction can be moderated by cold, but not arrested, because milk contains several species of bacteria capable of developing at 0° C. Diseased cows yield milk containing pathogenic organisms. Martin shows that 1 in every 13 samples of milk exposed for sale in Paris contained tubercle bacilli, and Dr Schroeder in Washington found that 1 in every 19 samples contained a sufficient number to produce infection. Milk also is often the carrier of the specific organisms of typhoid, cholera, scarlet fever, and foot-and-mouth disease.

Food preservatives.

Milk.—By treating milk to a temperature of 60° C. for one hour, 70° C. for ten minutes, and 95° C. for one minute, tubercle bacilli, if present, will certainly be killed. Cholera and typhoid organisms are less resistant, and are killed more quickly than tubercle bacilli at the above temperatures. Only a single pathogenic species can withstand the short boiling to which milk is ordinarily treated in domestic management, and this is the anthrax bacillus containing spores. The danger from this source is remote, as the microbe does not form spores within the animal body. Even in the worst cases, therefore, only vegetable forms, easily destroyed by boiling, can find their way into the milk from the body of the cow.

The lactic acid bacillus, always present in unboiled milk (to which the souring of milk is due), is easily destroyed by heat; but the *bacillus mesentericus*, often found in it, forms spores, which are not destroyed by ordinary boiling, and germinate when the milk is kept at a moderately warm temperature, producing a brisk fermentation whereby a large volume of gas is liberated. The fundamental idea of Soxhlet's method for sterilizing milk is to boil it for forty minutes in small bottles holding just enough for one meal, and closing the same with an impervious stopper, which is only removed just before use. Milk so treated will keep at the ordinary room temperature, as the spores of the *B. mesentericus* do not develop below 15° C.; but if it be introduced into the alimentary canal of a child the spores will rapidly multiply, and in such cases large quantities of gas, giving rise to flatulency, will be formed, and possibly also poisonous decomposition products of albuminoid matter. To render milk sterile in the strict sense of the word it is necessary to raise it to a temperature of about 120° C. for twenty minutes. Under these conditions the lactose decomposes into dark-brown fission products, the fat loses its emulsified condition and separates out as cream which cannot be made to diffuse again even by shaking, and the albuminoids are converted into a form very difficult of digestion.

In short, there is at the present time the greatest difficulty in freeing milk on a large scale from germs without at the same time seriously prejudicing its flavour and nutritive value. Since, then, the destruction of the hardy germs is so difficult, the greater care should be taken, by washing the udder, hands, and milk vessels, to secure extreme cleanliness in the preparation of milk intended for infant consumption. Sterilization then becomes an easier task, the milk drawn under these conditions being very poor in spore-forming bacteria. It is imperative that cream destined for butter-making should be free from pathogenic organisms. The organisms of cholera, typhoid fever, and tuberculosis present in butter retain their vitality for a long time. As butter is consumed in the raw state, a trustworthy preliminary treatment of the cream is in the highest degree desirable. Schuppan has shown that it is possible to produce good butter from Pasteurized or even sterilized cream, and Weigmann introduced the plan of artificially souring cream by means of pure cultures of *B. acidi lactici.* Boracic acid, salicylic acid, and even benzoic acid have been used as milk preservatives. The influence of small doses of boracic acid is still *sub judice;* it is hardly possible for so much as three or four grains a day to produce any deleterious effect. One objection to allowing boracic acid to be added to milk is that it enables the milkman to palm off stale milk as fresh. It would seem advisable to prohibit chemical preservatives altogether. In condensed milk many of the bacteria present are killed by the preliminary heating and the subsequent concentration at 50° to 60° C. A few survive and are still alive in the finished product, but not in a condition to do any damage, since the high concentration plasmolyses the germs, retarding their development and so preventing decomposition.

Meat.—In the preservation of meat we know that the blood and flesh of healthy animals are entirely free from bacteria, but, on the other hand, the contents of the digestive tract are extremely rich in microbes. If the carcase of a slaughtered animal be left without being disembowelled, these saprophytes will make their way through the capillary vessels of the intestinal wall into the general blood-system, so that the entire carcase quickly begins to undergo decomposition. This can be prevented by the excision of the entire length of the alimentary canal; and if this be practised the remaining flesh will be perfectly free from fungi. Any subsequent danger can only be due to gradual penetration from the surface. Since these sources of bacterial infection cannot be entirely cut off, attempts are made to prevent the increase of these parasites in the flesh. The oldest known remedy is cold, but the temperature must be kept several degrees below zero (C.). The freezing of meat does not kill the germs present, but only hinders their development. If the meat be not stored at low temperatures, but merely put in the ice-chest, whereby it only attains a temperature of 0° C., an increase of germs ensues. These cold-supporting organisms produce the disagreeable taste and smell acquired by edibles remaining in the ice-chest for a few days. Actual putrefaction is not produced by these bacteria. Food-stuffs should not be brought into actual contact with natural ice, since this substance contains not only putrefactive organisms, but also under certain conditions pathogenic organisms. Frozen meat when thawed undergoes rapid decomposition, because the cellular tissue is loosened by freezing, and access to the interior is facilitated for any organisms present on the surface.

In dried and salted meat the development and activity of the organisms can be prevented by depriving them of the water necessary for metabolism. In salting and pickling, it is only the hygroscopic power of the salt which comes into play; the germs are plasmolysed and so their activity is prevented. Tubercle bacilli are not killed by a concentrated solution of salt after two months' and typhoid bacilli after three months' action. Smoking forms a more certain means of preserving meat, the active agents being the vapours of phenol, creosote, &c., present in the smoke. These antiseptics do not penetrate far into the flesh, therefore smoking can only preserve the fresh meat taken from healthy animals.

Disinfection.

Disinfection by means of sulphur dioxide is now looked upon as quite inefficient, even when used in large amount, and has given place to formaldehyde, which is regarded as a powerful germicide. Schlossman states that there are two chief methods of carrying out this disinfection. In Trillat's method an attempt is made to prevent the formation of polymers of formaldehyde by adding calcium chloride, whereas in Schering's apparatus para-formaldehyde is converted into gas, and this is again changed into formaldehyde by means of the water produced by the burning of a certain amount of spirit. The probability is that in both methods the greatest part of the formaldehyde escaping into the air is converted into polymers. In the method introduced by Schlossman and Wallten polymerization is prevented by the use of glycerine.

Lingun has constructed an apparatus consisting of a vessel in which the water is boiled. The steam rises into a reservoir which contains 4 per cent. of formaldehyde and 10 per cent. of glycerine. From the reservoir four pipes pass into the room. A room with a cubic capacity of 2000 cubic feet is filled with vapour in ten minutes. All microbes are destroyed in three hours at the latest. The advantages claimed by Schlossman are: (1) Sterilization is absolute; (2) the closure of all cracks and clefts is not necessary; (3) the procedure requires only three hours; (4) there is no danger of explosions; (5) the method is cheap; (6) the glycoformal vapour is heavier than air, and therefore sinks; (7) the total disinfecting powers of the gas are obtained. The windows are thrown open for half an hour after the disinfection. Liquor ammonia is placed in the room in an amount proportional to the formaldehyde used. The windows are again opened, and thus all smell is got rid of. With Schering's method it has been found that rapid volatilization

is necessary to prevent the polymerization of the greater part of the formaldehyde vapour. Five tablets per 100 cubic feet appear to destroy anthrax cultures containing spores when smeared on linen and exposed in the room: pieces of linen soaked in broth cultures of *B. diphtheriæ* and *B. typhosus* were rendered sterile when five tablets in 100 cubic feet were rapidly converted into formaldehyde vapours by the heat and moisture derived from a large flame of Schering's lamp.

Quarantine. The first suggestion of an international conference on quarantine was made by the French Government in 1838, but so diverse were the views held on the subject, and its enforcement at stations and ports on the Mediterranean was so capricious, that various difficulties arose and the proposals fell through. In 1843 the British Government suggested a further conference; but this again was opposed as premature, since there was no foundation on which to base any regulations which would be acceptable to the Powers. In 1849–50 the wave of cholera which passed over Europe brought the subject again under notice, and a conference assembled in Paris in 1851 to consider the question of quarantine in relation to cholera, yellow fever, and plague, the only diseases for which this means of prevention was to be employed. The results were unsatisfactory; there was little unity of opinion, and no system of international control was possible in the circumstances. It rested with the chief medical officer of the Privy Council (Sir John Simon, K.C.B.) to raise the question of international control, and it was chiefly owing to the strong expression of his opinion that a scientific inquiry began, which ultimately led step by step to the almost total abolition of quarantine not only in Great Britain, but in countries under international control. Writing in 1865, Sir John Simon said, "There are two kinds of precautions which may be used against quarantine: first, if possible, to prevent the entrance of the contagion; secondly, if the contagion be present, to annihilate as far as possible the circumstances which favour its spread. Subject to one qualification, which is not an important one for the present argument, it may, I think, be accepted as certain that quarantine, conducted with extreme rigour and with the precision of a chemical experiment, will keep cholera out of every part of Europe in which the extremely difficult conditions can be absolutely fulfilled; and thus, if I speak to the dry question of medical practice, I have no hesitation in saying that England ought to resist cholera by quarantine. On the other hand, though I cannot pretend to discuss with any kind of authority the non-medical aspects of the question, it would be mere pedantry for me to ignore that facts which are of common notoriety and considerations which are of common sense conflict with that medical conclusion. A quarantine which is ineffective is a mere irrational derangement of commerce, and a quarantine which ensures success is more easily imagined than realized. Only in proportion as a community lives apart from the great highways and emporia of commerce, or is ready and able to treat its commerce as a subordinate political interest, only in such proportion can quarantine be made effectual for preventing it. In proportion as these circumstances are reversed, it becomes impossible to reduce to practice the paper plausibilities of quarantine. The conditions which have to be fulfilled are conditions of natural seclusion, and fulfilment of such conditions by England would involve fundamental changes in the most established habits of the country."

The next international conference was held in Constantinople in 1866. This conference came to the conclusion that cholera had always its origin in India, and that its extension followed the lines of human intercourse. They were of opinion that quarantine was capable of arresting the disease. There should be quarantine of observation and quarantine of rigour. Strict quarantine was to be applied to all ships from an infected port with a foul bill of health, as well as to any vessel which had cases on board during the voyage, although provided with a clean bill of health. The term fixed was ten days from the time of entering any port, to recommence if any case occurred thereafter. Quarantine of observation was to consist of keeping isolated and under observation for an indefinite time—to be fixed by the local authority—a vessel with crew and passengers, with free ventilation but no disinfection. Strict quarantine was defined as isolation for a fixed time of a ship and persons on board, with disinfection of all that might contain the germs of disease. The whole of the cargo was to be landed and the passengers disembarked at a lazaret. In 1873, so far as cholera was concerned, quarantine was officially abandoned by order of the Local Government Board. In 1874 an international sanitary conference was held at Vienna, the object being to arrange among the Powers interested compulsory regulations having for their object to bring about a perfect uniformity in the measures to be adopted against the common danger. This conference was the first which in any form gave sanction to the principle of medical inspection taking the place of quarantine. France was the only one of the Great Powers that still adhered to quarantine. The conference reaffirmed the decision as to the place of origin and transmission of cholera arrived at in Constantinople. Another international conference was held in Rome in 1885. In the matter of disinfection it was for the first time distinctly laid down that it is not necessary to consider articles as infected merely because they came from a country where cholera prevailed; that only persons or articles that have been actually soiled by choleraic discharges, and articles that have been worn by persons suffering from cholera, ought to be subjected to such a process; and that, in the case of individuals, disinfection by means of baths ought alone to be resorted to, fumigation being thus incidentally condemned as useless. But in the conclusions of this conference medical inspection finds no place, except in so far as this term may stand for a formal preliminary (1) to a detention of twenty-four hours in cases where the sea voyage has lasted less than ten days, and (2) to the imposition of quarantine detention varying from three to six days on sick and healthy alike. An international sanitary conference met again at Venice in 1892. It dealt solely with the question of cholera. It was convened to consider the regulations then existing relative to transit in quarantine by the Suez Canal. The delegates were asked to notify what modifications should be introduced into the constitution of the Sanitary Council of Marine and Quarantine of Egypt, and generally the constitution of that council.

There has always been a considerable divergence between the view held by medical authorities and accepted by public opinion in England and in India, and that prevailing on the Continent, as to the efficacy of quarantine against the contagion of cholera and some other infective diseases. The tendency of British opinion throughout this long controversy has been to look to measures of sanitary improvement as the best prophylactic against cholera, and to rely on the application of quarantine for that purpose only to a very small degree, whereas on the Continent the belief in quarantine, though apparently diminishing, retains still much of its actual force. The conclusions of the Venice conference briefly were as follows. Instead of a prescribed five days' detention of *all* passengers, other than those sick of cholera, at Moses Wells, in the case of vessels without a doctor or a disinfecting stove on board, the detention will vary according to a sliding scale from forty-eight hours to five days. In case of a vessel carrying a doctor and a disinfecting stove, it is the doctor on board who is to decide what person or persons are to be landed, on the ground that they are suffering from cholera. Thus there is a guarantee against British subjects suffering from dysentery being landed compulsorily. If any landing of a limited number of such passengers or crew does take place, it will only occur when it is necessary for the purpose of disinfecting a portion of the vessel. Even then there is an alternative of removal to a vessel moored alongside, and any such removal is for a limited number of hours only, after which the persons in the vessel have a right to return to the ship. Thus no compulsory landing of any healthy persons can take place. It will be seen that the Venice conference only dealt with the transmission of cholera *by sea* into Europe.

A conference was held in Dresden in 1893 to complete, so to speak, the work of the previous conference. It was convened to consider (1) the precautions to be adopted *on land* and *sea ports* against cholera, (2) the special conditions affecting the Danube, and (3) the organization of the board of health at Tehran; but these last two points were apparently not raised or discussed. The convention provided a minimum and a maximum precaution. The minimum is obligatory. It corresponds closely with the provisions of the cholera regulations in Great Britain. Practically the only difference is that the medical supervision of persons landing from an "infected" ship is in Great Britain carried out at their own homes, whereas under the convention such persons are to be detained for a period not exceeding five days from the date of the last case on board. By the Dresden convention no ship will be

detained in any port where there is a hospital for the sick, and all other persons are, if possible, to be disembarked. The maximum of precautions laid down by the convention constitutes a limit which no state may exceed. The most important difference between minimum and maximum occurs in the treatment of healthy ships coming from cholera-infected ports. Such ships are always to receive immediate *pratique*. As a minimum of precaution, bilge- and drinking-water must be evacuated, and persons landed from such ships may be subjected to medical supervision at home without any detention. With regard to disinfection also, there is a difference between the minimum and maximum in the case of infected ships, the minimum being that part of the ship actually contaminated shall be disinfected; the maximum, that the whole ship may be disinfected. Under the convention all goods are freed from restrictions, except fresh rags and things believed to be "contaminated," *i.e.*, fouled with cholera matters. The measures to be applied to land frontiers are analogous to those for seaports, with the important exception that only those persons suffering from cholera may be detained on land frontiers. The greater precaution taken in seaports than on land frontiers was due to the opinion that risk of infection on board ship is far greater than in a train. If a case of cholera occurred in a train, the healthy would leave the carriage at the next station, or would even stop the train, and therefore would be exposed to the risk of infection for a very short time only. The conclusions adopted by this conference embody the principle of notification of cholera, and aim at preventing certain unreasonable measures of restriction against countries in which cholera has appeared.

The next international conference was convened under the auspices of the French Government at Paris in 1894, with a view of devising measures for preventing the spread of cholera by way of the Red Sea and the Persian Gulf. At Venice in 1892, and at Dresden in 1893, sanitary conventions were concluded to the effect that precautions must be taken on the accepted basis that cholera is communicated by human agency and on lines of human intercourse. The Paris conference really began where the two previous ones left off. The first point discussed was as to the necessity of requiring a medical inspection of all persons on board a pilgrim ship before embarkation. The conference was assured that this was strictly carried out by Great Britain and British India not only as to cholera, but as to all infectious diseases, and the proposal of the requirement was unanimously accepted. A second proposal related to the disinfection of all articles deemed "contaminées" or "suspect" in accordance with the Venice convention; and, subject to the understanding that the medical officer of health of the port was to be the judge as to what articles came under these definitions, the proposition was carried. A third proposal forbidding the embarkation of any passengers deemed to be infected or suspected of being so was also unanimously agreed to. At a full meeting of the conference the heads were arrived at:—(1) Sanitary police at the ports of departure; (2) Measures to be adopted on board pilgrim ships; (3) Sanitary surveillance over pilgrimages in the Red Sea; (4) Surveillance over the pilgrims going by land to Mecca and Medina. In this, as in all previous conferences, vessels were classified as follows: (*a*) "indemnes"; (*b*) "suspects"; (*c*) "infectés." "Navires indemnes" are those ships in which no case of cholera has existed before starting or during the voyage. These receive immediate *pratique* whatever their bill of health may be. "Navires suspects" are those in which any case of cholera has arisen within seven days. These receive medical visits, and are subjected to disinfection, &c., and there is a recommendation (1) as to maintaining the passengers under observation for five days from the date of leaving the port of departure; and (2) as to preventing the landing of the crew except in case of necessity. "Navires infectés" are those in which any case of cholera has arisen within seven days before arrival. The sick and remainder of the passengers are obliged to disembark and to undergo detention under observation for a period of five days at the outside, to date from the occurrence of the last case of cholera. Disinfection of clothing is also compulsory.

In 1897 an international conference assembled at Venice. This was in connexion with the outbreak of plague in the East, and the conference met to settle on an international basis the steps to be taken to prevent, if possible, its spread into Europe. One of the first points to be dealt with was to settle the incubation period for this disease, and the period to be adopted for administrative purposes. It was admitted that the incubation period was, as a rule, a comparatively short one, namely, of some three or four days. After much discussion ten days was accepted by a very large majority. The principle of notification was unanimously adopted. Each Government is to notify to other Governments the existence of plague within their several jurisdictions, and at the same time state the measures of prevention which are being carried out to prevent its diffusion. The area deemed to be infected is limited to the actual district or village where the disease prevails, and no locality is deemed to be infected merely because of the importation into it of a few cases of plague while there has been no diffusion of the malady. As regards the precautions to be taken on land frontiers, it was decided that during the prevalence of plague every country had the inherent right to close its land frontiers against traffic. As regards the Red Sea, it was decided after discussion that a healthy vessel may pass through the Suez Canal, and continue its voyage in the Mediterranean during the period of incubation of the disease the prevention of which is in question. It was also agreed that vessels passing through the Canal in quarantine might, subject to the use of the electric light, coal in quarantine at Port Said by night as well as by day, and that passengers might embark in quarantine at that port. Infected vessels, if these carry a doctor and are provided with a disinfecting stove, have a right to navigate the Canal in quarantine, subject only to the landing of those who are suffering from plague, and of such persons as have been in actual contact with the sick or with infected articles, together with the disinfection of the infected compartment of the vessel. Passing on to the conclusions dealing with regulations to be imposed "in Europe," the following are the chief points to be noted:—As regards measures to be adopted at ports of arrival, the conclusions of the Dresden convention were as far as practicable adhered to. In the case of healthy vessels, *i.e.*, those on board of which there is no illness, though they have sailed from an infected port, it was decided that they should at once have free *pratique*, but at the option of the local authority certain measures of disinfection of soiled articles may be required. For suspected vessels, viz., those on board of which there has been plague, but no fresh case within twelve days, some limited processes of disinfection, &c., as defined, having been complied with, it is recommended that the crew and passengers should be subject to surveillance for a period of ten days from the date of the arrival of the vessel. In the case of infected vessels, viz., those on which plague is actually present, or on which that disease has occurred ten days before arrival, the sick are to be landed and isolated, and the remainder of those on board are to be subjected, at the discretion of the local authority, to "observation" or "surveillance" for a period not exceeding ten days from the date of the occurrence of the last case of plague. In this convention the terms "observation" and "surveillance" are for the first time clearly defined; the definition as to the latter stating that under that system passengers are not to be isolated, but are to be allowed at once to proceed to their homes, where they can remain under medical supervision so long as may be deemed necessary by the local authority. The results of this conference indicated a great advance on the part of the nationalities represented towards a liberal and truly scientific conception of the means to be adopted by their respective Governments for the prevention and control of infective diseases. (J. L. N.)

Conference of 1897.

Hypnotism.—Under the name of hypnotism a remarkable revival of what used to be called mesmerism or animal magnetism has taken place. It began in France about 1880, and has attracted much scientific and popular interest. It is a common experience that when the attention of persons is for the first time drawn to a thing, they are apt to regard what is new to themselves as altogether new. This has conspicuously happened in regard to hypnotism. Extravagant claims of novelty and utility have been made on its behalf, but

there is really nothing new either in the phenomena or in the hopes founded on them. All that has been added to previous experience is the investigation of certain aspects of the subject in a somewhat more systematic manner and in the light of somewhat fuller knowledge. This has resulted in establishing the reality of the main phenomena on a firm basis of accurate observation, but no substantial advance has been made in the explanation of their nature or in their application to medical practice. Any belief to the contrary is founded on ignorance of what has been done in the past. In order to make clear the precise value of the recent revival, a brief historical retrospect is necessary. (See also MAGNETISM, ANIMAL, *Ency. Brit.* vol. xv.)

In a sense the phenomena of hypnotism have probably been known from time immemorial. They appear to form part of certain traditional practices of great antiquity in the East, and traces of them may be found in classical and mediæval times, but they were first brought forward in a systematic way by Friedrich Anton Mesmer, a Viennese physician who flourished in the latter half of the 18th century. He stumbled across them accidentally in the year 1774, while treating a young woman for hysteria by the application of metal plates. In 1778 he came to Paris, where he soon attracted attention and acquired a vogue which his professional colleagues could not forgive and have not to this day forgiven. No doubt he practised in a highly theatrical and unorthodox manner, and made a great deal of money by doing so, but he did not profess to cure everything, as some modern hypnotists do, and expressly disclaimed any value for his treatment in organic disease. The methods of producing the mesmeric "crisis" were essentially the same as those used to-day for putting persons into the hypnotic state, namely, various ways of fixing the visual and mental attention. "His usual method was to seat himself opposite the patient with knees touching, the patient regarding him fixedly." The effects were also essentially the same—trance, somnambulism, subordination of the will, and impressibility. Mesmer called it animal magnetism, and formulated an elaborate theory on the subject, but most of his propositions are fantastic and unintelligible, though some of his speculations have been curiously confirmed in later years. He had many followers, who carried on the practice after his retirement in 1785, and notably the marquis de Puységur, who anticipated nearly everything that has been done since. After the Revolution, which put a temporary stop to animal magnetism, it was taken up again and flourished widely on the Continent. The Berlin Academy of Science offered a prize for the best essay on the subject. Mesmerism was practised in the hospitals, and minor operations were performed under mesmeric anæsthesia. That was about 1820. In 1831 a commission, appointed by the Académie de Médecine, issued a very favourable report after an inquiry lasting five years. The reality of the phenomena, including somnambulism and its effects, was declared to have been proved, but a second commission in 1837 reversed the decision and threw the whole thing into discredit. The next phase was the re-discovery of what had been discovered before, with the addition of a new name and a new theory. This was the work of James Braid of Manchester, who invented the word Hypnotism, and maintained that the mesmeric phenomena were not caused by a magnetic fluid, but depended on the "physical and psychical condition of the patient, irrespective of any agency proceeding from or excited into action by another." He was led to take up the study in 1841 by witnessing the public performance of a mesmeric entertainer. Neither his methods nor his results differed essentially from those of earlier mesmerists, but he undoubtedly put the thing on a more rational and more scientific basis. He himself suggested that hypnotism might be called "rational" as opposed to "transcendental mesmerism." His success in the therapeutic application of hypnotism was not conspicuously greater than that attained many years before in France. He published his *Neurypnology* in 1843. The word was coined to signify the science of "nervous sleep," but it is not a good one. Natural sleep is "nervous," and hypnotism is not sleep. Braid, in fact, made very much the same mistake as Mesmer in adopting an inadequate or erroneous theory, and viewing all the facts in the light of it. About the same time, but quite independently, a Scots surgeon named Esdaile was practising mesmerism in India, chiefly for producing anæsthesia, which he succeeded in doing with natives to an extent never since approached. He performed upwards of 300 major operations under mesmeric anæsthesia in the Indian hospitals, and otherwise showed a complete mastery of the art. On one occasion he hypnotized a man behind his back and without his knowledge in open court. The affections treated by Braid included various forms of paralysis, neuralgia, nervous headache, hysteria, epilepsy, defects of sight, hearing, smell, and speech, palpitation of the heart, dyspepsia, spinal irritation, club foot, curvature of the spine, some skin diseases, and rheumatism. He disclaimed any wish "to hold it [hypnotism] up as a universal remedy," nor did he profess to understand fully how the effects were produced, but he held that "besides the peculiar impression directly made on the nervous centres, by which the mind is for the time thrown out of gear, and which enables us to localize or concentrate the nervous energy or sensorial power to any particular point or function, we have also an extraordinary power of acting on the capillaries and of increasing and diminishing the force and frequency of the circulation, locally and generally." Experience led him to modify his earlier opinion that the hypnotic state is quite independent of the agency of the operator, and he himself made use of mesmeric "passes." Braid's investigations attracted a good deal of attention, but were not favourably received in scientific and orthodox circles, with some exceptions; and they excited the hostility of the mesmerists, who did not like to see their theory of a magnetic fluid overthrown. Throughout the history of the subject—indeed, from Mesmer down to the Nancy school—exponents and opponents alike have been more given to controversy over theories than to the patient investigation of facts. Braid, however, made some distinguished converts among unprejudiced men to whom the facts appealed, and they seem to have realized the bearing of certain phenomena better than he did himself. Notably they developed the importance of suggestion, and fully anticipated the Nancy school of modern hypnotists. Suggestion was nothing new, having been known to Mesmer, but its significance had been missed by the earlier mesmerists, who believed in a magnetic fluid. Braid appreciated it better, and pointed out that "the sleeper" exhibits "physical manifestations of the suggestion received through words or excited by sensible impressions which thereby direct his current of thought," and also that "definite physical changes could be excited and regulated and controlled at will, according to the suggestion of another person"; but it was more clearly and more fully recognized by Dr Gregory, professor of chemistry at Edinburgh. In a book on mesmerism, published in 1851, he says, "It must be at once obvious to every person acquainted with physiology that the peculiar phenomena now under consideration depend on the principle of suggestion," and further, "it is self-evident that the power of suggestion may be usefully

applied in medicine." Professor Hughes-Bennett, a physician of high standing, said in his lectures about the same time that it was clear "that the effect is produced by operating on the mind of the individual, and through that on his bodily powers. In short, predominating ideas, whether originating spontaneously or suggested by the words and actions of others, seem to be the exciting cause in individuals affected with a peculiar condition of the cerebral functions. The labours of Dr Esdaile in India and Mr Braid of Manchester exhibit a worthy commencement in the rational treatment of disorders by the means alluded to, and there can be little doubt that in no long time its influence, when further studied, will be acknowledged." Hypnotic suggestion was used in medicine in the manner indicated, also for the production of anæsthesia and the treatment of dipsomania; but its value was not generally acknowledged, and it gradually dropped out of sight. Evidently it did not fulfil expectations; it ceased to attract public or scientific attention, and fell into disuse. This fact, after the complete recognition of its nature just quoted, and the sanguine hopes entertained of its utility, is of the greatest significance.

For some thirty years mesmerism or hypnotism was dormant, save for the travelling showman and a few adherents in France, who readily embraced the opportunity of practising the tabooed art under a new name, and even succeeded in smuggling it into the Academie des Sciences. But it excited only a brief spasm of interest, and the subject dropped until the revival initiated by Charcot. In the year 1877 he was nominated to investigate and report on the treatment of nervous diseases with metal discs, introduced by Burq. He found the phenomena genuine, and continued the study in his own wards. Experimenting on cases of hysteria, he soon came across the hypnotic or mesmeric condition, and recognized its reality. In short, by the irony of fate the most distinguished of French physicians, treading exactly in the steps of Mesmer, who also began by experimenting on hysterical patients with metal plates, once more re-discovered the whole thing just a hundred years later. His name soon gave an impetus to the study, and an extensive revival followed. Hypnotism became orthodox, and the few French physicians who had been practising it quietly came out into the light of day. Among them was Dr Liébeault of Nancy, who had been using hypnotism for twenty years. His academic colleagues in that city, who had ignored him hitherto, now sought inspiration from his experience, and he became the father of what was called the Nancy school of hypnotism. Its distinguishing mark was the supreme importance attached to suggestion. According to the most advanced exponents of the Nancy school, there is nothing in hypnotism except suggestion, which is a universal therapeutic agency or "cure all"—if, indeed, all treatment is not a form of suggestion. On the other hand, the "Paris school," following Charcot, regarded hypnotic susceptibility as a morbid condition allied to hysteria. The rise of these rival schools dates from about 1880. At the same time Heidenhain of Breslau embarked independently on the study of mesmerism from a physiological point of view, obtaining his first instruction from a travelling mesmerist, as Braid did. Heidenhain fully established the reality of the phenomena, and formulated a theory that they are due to inhibition of the higher centres in the brain, caused by rhythmical stimulation of the senses. One of his experiments is particularly interesting, because it proves that persons can be hypnotized against their will, and that the condition is not, therefore, purely "subjective." Prussian soldiers were mesmerized and sent to sleep upon parade, though they had the strongest reasons for not committing such a serious breach of discipline. From 1880 onwards the vogue of hypnotism increased rapidly, until it culminated in 1889, when an International Hypnotic Congress was held in Paris. It was attended by representatives from every European nation and from North and South America, and among the honorary presidents were Charcot, Brown-Séquard, Brouardel, Richet, and Lombroso. For two or three years after this hypnotism continued to excite great interest, and sanguine expectations were entertained of its future usefulness in medicine, but the excitement did not last long. Interest once more began to languish, and at present the practice, which never obtained a general hold upon the medical profession, appears to be falling again into neglect.

The foregoing summary will suffice to show that animal magnetism, mesmerism, and hypnotism have a continuous history, and are essentially one and the same thing, which has undergone a series of revivals under different names and in connexion with different theories. The service rendered by the latest revival is not that it has introduced anything new, but that it has established the existence of the hypnotic or mesmeric condition with an authority which must carry conviction to all minds capable of judging evidence. The same phenomena have been re-discovered again and again since Mesmer's time. If they are not real, then it must be supposed that a vast number of persons of all classes and nationalities, including the most ignorant peasants and Orientals, have entered into a conspiracy to deceive for more than a century past, with no real object in view, and often at the cost of great pain to themselves, and have learnt their lesson so well that they all behave in the same way and reproduce the same symptoms so skilfully as to delude hundreds of the most acute and most sceptical observers. This is too large a draft upon the credulity of any one. Scepticism is justified in the case of all exhibitions and paid subjects, who have repeatedly been convicted of trickery, and should never be trusted. But the investigations of medical men and physiologists, carried out upon genuine hospital patients and other subjects of unimpeachable honesty in all classes of life, stand on a different footing. Nor should the phenomena be confounded with the theories invented to explain them. This was the mistake made by the earlier critics of mesmerism; with the exception of the French commission of 1825, and a few other clear-headed observers, they devoted their attention to the supposed magnetic fluid and, ignoring the phenomena, pronounced the whole thing a delusion because the existence of the magnetic fluid was not proved to their satisfaction.

The main facts established may be summarized as follows:—(1) The hypnotic state may be induced in various ways. The most usual are fixation of the gaze on some object; gentle monotonous stimulation of any of the senses; a sudden flash of light or loud noise; passes by the hand; a command or suggestion to go to sleep. Some of these may be combined. Occasionally subjects pass spontaneously into the state. Return to the normal is effected by the command to wake up, which may be assisted by a slight physical stimulus, such as a light tap or blowing in the face. When left to themselves subjects awake spontaneously after a time. Natural susceptibility varies greatly. Some persons are affected at once, and even against their will. Others remain wholly refractory, though willing and even anxious to be hypnotized. Susceptibility is always increased by practice. Some operators are more successful than others. Certain races appear to be far more susceptible than others, the French, for instance, more than the English. In Paris hypnotization has been effected by a revolving instrument resembling that used to attract larks. The

clinique of patients at the Charité Hospital gazing at this object and falling into trances exactly recalls Mesmer's *baquet*. (2) Subjects are very variously affected, but the commonest effects are conditions resembling sleep, trance, or catalepsy, and somnambulism, in which ordinary consciousness is lost, and the subject renders implicit obedience to the operator, remembering nothing on waking up. Certain physiological phenomena have been observed. The muscles contract on being stroked, and the whole body may be rendered rigid; the senses may be enormously heightened, so that sounds can be heard and odours smelt at far greater distances than in the normal state, and print can be read through layers of cotton-wool or a wooden screen; the circulation may be affected by modifying the action of the heart and by causing the blood-vessels, especially the capillaries, to contract or dilate; according to Charcot, it has been ascertained by exact observation with instruments of precision that the blood-vessels undergo regular changes in certain hypnotic states, contracting in some and dilating in others; the respiration may be slowed or quickened; regular changes also take place in the secretions, and the action of various glands may be modified at pleasure; anæsthesia and paralysis may be produced. The psychological phenomena occur in the somnambulistic state, and are mostly manifestations of an extreme susceptibility to suggestions, which may be conveyed by word of mouth, by gestures and signs, or by some other agency acting through one of the senses. The mind and will of the subject are blank, ready to receive and act upon any idea impressed upon them. This phase of hypnotism is the basis of mesmeric exhibitions on the one hand and of its therapeutic application on the other. There seems hardly any limit to the obedience of susceptible subjects in the somnambulistic state, but the fears that it might be used to procure the commission of crime have not been realized. One of the most striking phenomena produced is that of "post-hypnotic suggestion," in which the subject on awaking executes an order previously given during the somnambulistic condition without any recollection or consciousness of the source of the impulse, and it may be after the lapse of a considerable interval of time. The effects of suggestion are greatly heightened in some subjects by a marked increase of intellectual and emotional power, analogous to the exalted capacity of the special senses, which enables them to perform feats of which they are totally incapable in their ordinary condition. A peculiar relation is established between the operator and the subject, who ignores every one else.

Such are the principal phenomena of hypnotism, but it must be understood that some of them are rather rare, and only produced in specially susceptible subjects. The still rarer effects described by the older mesmerists, such as clairvoyance, telepathy, and "presensation," have not been observed by recent investigators, but Charcot describes some very similar phenomena, and it would be highly unscientific to pronounce them impossible merely because they are outside the range of ordinary experience. Theories of hypnotism are legion. Some are discussed elsewhere (see PHYSIOLOGY, *Nerve and Muscle*). They have only an academic or controversial interest. Until the normal working of the brain is better understood, it is futile to speculate on such an abnormal condition as the hypnotic.

There remains the practical application of hypnotism in medicine. Modern experience has not materially enlarged its utility. It has been used for the most part in the same class of cases as during previous flourishing periods — namely, in functional disorders of the nervous system and for the relief of pain. The only distinctively novel application is that attempted by the Nancy practitioners, who professed to find a sovereign remedy in suggestion, and used it in every class of disease, including the specific fevers. The success of this new departure has been less conspicuous than its boldness. Speaking generally, the sanguine hopes of enthusiastic hypnotizers have not been realized, and the attitude of the bulk of the profession in holding aloof from the practice while admitting the reality of the hypnotic phenomena has been fully justified. Charcot himself abandoned the use of hypnotism because he found that it did more harm than good and merely added to the disorder of already disordered nervous systems. Others have followed his example; and though a faithful few may still remain constant to their faith in the virtues of suggestion, it cannot be said that their number or their credit is increasing. This is precisely what might have been expected. History is only repeating itself once more. Had there been any real value in the thing, it would never have fallen into neglect in the 'thirties and again in the 'fifties. Its successive revivals have been due to the reality of the phenomena, which continually reassert themselves with all the indestructible force of truth; its successive periods of decline have been due to inherent weakness and therapeutic inutility. The hypnotic state and its effects are too uncertain, too capricious, and too dangerous for general use in medicine. (A. SL.)

Hythe, a municipal borough of Kent, England, 67 miles south-east of London by rail. Recent erections include a sessions hall and an institute. The sea-wall and parade, belonging to the South-Eastern and Chatham Railway, and the buildings of the Royal School of Musketry, have been extended. There is constant communication with Sandgate by means of a tramway along the front, and an excellent golf-course has been laid out on the downs. Area, 2620 acres. Population (1881), 4173; (1901), 5557.

Ibagué, or SAN BONIFACIO DE IBAGUÉ, chief town in the department of Tolima, in the Republic of Colombia, South America. It is picturesquely situated on a beautiful plain 4300 feet above sea-level, between the rivers Chipalo and Combeimna, affluents of the Cuello, about 18 miles north-west of the Nevada del Tolima. With the Magdalena river it is connected by rail to Girardot, and it is the entrepôt of the valleys of Magdalena and Cauca. There are two thermal springs in the environs, and unexploited mines of sulphur and silver. The chief productions of the district are cacao, tobacco, rice, and sugar-cane. The city dates from 1550. In 1854 it was for a short time the capital of the Republic. Population, about 13,000.

Ibsen, Henrik (1828———), Norwegian dramatic and lyric poet, eldest son of Knud Ibsen, a merchant of the small Norwegian seaport of Skien, and of his wife, Maria Cornelia Altenburg, was born at Skien, in a house on the market-place now destroyed, on the 20th of March 1828. For five generations the family had consisted on the father's side of a blending of Danish, German, and Scottish races, with little intermixture of pure Norwegian; this last element was contributed by the mother. In 1836

Knud Ibsen became insolvent, and the family withdrew, in great poverty, to a cottage in the outskirts of the town. After brief schooling at Skien, Ibsen was sent, towards the close of 1843, to be apprenticed to an apothecary in Grimstad; here he remained through seven dreary years of drudgery, which set their mark upon his spirit. In 1847, in his nineteenth year, he began to write poetry. He made a gloomy and almost sinister impression upon persons who met him at this time, and one of his associates of those days has recorded that Ibsen "walked about Grimstad like a mystery sealed with seven seals." He had continued, by assiduous reading, his self-education, and in 1850 he contrived to leave his narrow conditions and come up as a student to Christiania. In the same year he published his first work, the blank-verse tragedy of *Catilina*, under a pseudonym. A second drama, *The Viking's Grave*, was acted (but not printed) a few months later; he was at this time entirely under the influence of the Danish poet Oehlenschläger. During the next year or two Ibsen made a very precarious livelihood in Christiania as a journalist, but in November 1851 he had the good fortune to be appointed "stage-poet" at the little theatre of Bergen, with a small but regular salary. He was practically manager at this house, and he also received a travelling stipend. In 1852, therefore, he went, to study the stage, to Copenhagen and to Dresden. Among many dramatic experiments which Ibsen made in Bergen, the most considerable and most satisfactory is the saga-drama of *Mistress Inger at Östraat*, which was produced in 1855; here are already perceptible some qualities of his mature character. Much less significant, although at the time more successful, is *The Banquet at Solhaug*, a tragedy produced in Bergen in the first days of 1856; here for a moment Ibsen abandoned his own nascent manner for an imitation of the popular romantic dramatist of Denmark, Henrik Hertz. It is noticeable that Ibsen, by far the most original of modern writers for the stage, was remarkably slow in discovering the true bent of his genius. His next dramatic work was the romantic tragedy of *Olaf Liljekrans*, performed in 1857, but unprinted until 1898. This was the last play Ibsen wrote in Bergen. In the summer of the former year his five years' appointment came to an end, and he returned to Christiania. Almost immediately he began the composition of a work which showed an extraordinary advance on all that he had written before, the beautiful saga-drama of *The Warriors in Helgeland*, in which he threw off completely the influence of the Danish romantic tragedians, and took his material directly from the ancient Icelandic sources. This play marks an epoch in the development of Norwegian literature. It was received by the managers, both in Christiania and Copenhagen, with contemptuous disapproval, and in the autumn of 1857 Ibsen could not contrive to produce it even at the new theatre of which he was now the manager. *The Warriors* was not acted anywhere until 1861. During these years, Ibsen, in constant opposition, suffered many reverses and humiliations, but he persisted, in the face of all, to pursue his own line in art. Some of his finest short poems, and amongst others the admirable seafaring romance of *Terje Vigen*, belong to the year 1860. The annoyances which Ibsen suffered, and the retrograde and ignorant conditions which he felt around him in Norway, developed the ironic qualities in his genius, and he became an acid satirist. The brilliant rhymed drama, *Love's Comedy*, a masterpiece of lyric wit and incisive vivacity, belongs to 1862. This was a protest against the official conventionality which deadens the beauty of all the formal relations between men and women, the pettiness, the publicity, and the prosiness of betrothed and married life among the middle classes in Norway. It showed how society murders the poetry of love. For some time past Ibsen had been meditating another of his saga-dramas in prose, and this appeared in 1864 as *Kongsemnerne* ("The Pretenders"). These works, however, now so universally admired, contained an element of strangeness which was not welcome when they were new. Ibsen's position in Christiania grew more and more disagreeable. He had positive misfortunes which added to his embarrassment. In 1862 his theatre became bankrupt, and he was glad to accept the poorly-paid post of "æsthetic adviser" at the other house. An attempt to obtain a poet's pension (*digtergage*) was unsuccessful; the Storthing, which had just voted one to Björnson, refused to do the same for Ibsen. His cup was full of disillusion and bitterness, and in April 1864 he started, by Berlin and Trieste, ultimately to settle in Rome. His anger and scorn gave point to the satirical arrows which he shot back to his thankless fatherland from Italy in the splendid poem of *Brand*, published in Copenhagen in 1866, a fierce attack on the Laodicean state of religious and moral sentiment in the Norway of that day; the central figure, the stern priest Brand, who attempts to live like Christ and is snubbed and hounded away by all his latitudinarian companions, is one of the finest conceptions of a modern poet. Ibsen had scarcely closed *Brand* before he started a third lyrico-dramatic satire, *Peer Gynt* (1867), which remains, in a technical sense, the most highly finished of all his metrical works. In *Brand* the hero had denounced certain weaknesses which Ibsen saw in the Norwegian character, but these and other faults are personified in the hero of *Peer Gynt;* or rather, in this figure the poet has pictured, in a type, the Norwegian nation in all the egotism, vacillation, and lukewarmness which he believed to be characteristic of it. Ibsen, however, acted better than he preached, and he soon forgot his abstraction in the portrait of Peer Gynt as a human individual. In this magnificent work modern Norwegian literature first rises to a level with the finest

European poetry of the century. In 1869 Ibsen wrote the earliest of his prose dramas, the political comedy of *The Young Men's League*, in which for the first time he exercised his extraordinary gift for perfectly natural and yet pregnant dialogue. Ibsen was in Egypt, in October 1869, when his comedy was put on the stage in Christiania, amid violent expressions of hostility; on hearing the news, he wrote his brilliant little poem of defiance, called *At Port Saïd*. By this time, however, in spite of the antagonism of the critics and of certain sections of the public, Ibsen had become a successful author; *Brand* sold largely, and has continued to be the most popular of Ibsen's writings. In 1866, moreover, the Storthing had at last been persuaded to vote him a "poet's pension," and there was now an end of Ibsen's long struggle with poverty. In 1868 he left Rome, and settled in Dresden until 1874, when, after a voluntary exile of ten years, he returned to Norway. But after a short visit he returned to Germany, and lived first at Dresden, afterwards at Munich, and did not finally settle in Christiania until 1891. His shorter lyrical poems were collected in 1871, and in the course of that year his name and certain of his writings were for the first time mentioned to the English public. During these years, however, he was engaged on no new work, but was very carefully revising the old ones, which were now out of print, and which he would not resign again to the reading world until he had subjected them to what in some instances (for example, *Mistress Inger at Östraat*) amounted to practical recomposition. In 1873 he published a huge double drama, each part of which was of unusual bulk, the whole forming the tragedy of *Emperor and Galilean;* this is Ibsen's latest historical play, and has for subject the unsuccessful struggle of Julian the Apostate to hold the world against the rising tide of Christianity. This work is of an experimental kind, and takes its place between the early poetry and the later prose of the author, without properly belonging to either class. Compared with the series of plays which Ibsen was now about to begin, which indeed he had already inaugurated with *The Young Men's League*, *Emperor and Galilean* preserves a colour of idealism and even of mysticism which was for many years to be absent from Ibsen's writings, and to reappear in his old age with *The Master-builder*. There is some foundation for the charge that Ibsen has made his romantic Greek emperor needlessly squalid, and that he has robbed him, at last, too roughly of all that made him a sympathetic exponent of Hellenism. Ibsen was now greatly occupied by the political spectacle of Germany at war in Denmark, then at war in France, and he believed that all things were conspiring to bring the old order of national ideas to a close in Europe, and to start a new epoch of individualism. He was therefore deeply disgusted by the Paris commune, and disappointed by the conservative reaction which succeeded it. This disillusion in political matters had a very direct influence upon Ibsen's literary work. It persuaded him that nothing could be expected in the way of reform from democracies, from large blind masses of men moved capriciously in any direction, but that the sole hope for the future must lie in the study of personality, in the development of individual character. He set himself to diagnose the conditions of society, which he had convinced himself lay sick unto death. Hitherto Ibsen had usually employed rhymed verse for his dramatic compositions, or, in the case of his saga-plays, a studied and artificial prose. In spite of the surprising achievements of his poetry, he determined to abandon versification altogether for the future, and to write only in the language of everyday conversation. In the first drama of this his new period, *The Pillars of Society* (1877), he dealt with the problem of hypocrisy in a small commercial centre of industry, and he drew in the Bernick family a marvellous picture of social egotism in a prosperous seaport town. There was a certain similarity between this piece and *A Doll's House* (1878), although the latter was much the more successful in awakening curiosity. Indeed, no production of Ibsen's has been so widely discussed as this play, which is nevertheless not his most coherently conceived. Here also social hypocrisy, the convention which goes on covering up and patching together the rotten texture of life instead of rending it away, was the object of the playwright's satire, but this time mainly in relation to marriage. In *A Doll's House* Ibsen first developed his views with regard to the individualism of woman. In his previous writings he had depicted woman as the devoted and willing sacrifice to man; here he begins to explain that she has no less a duty to herself, and must keep alive her own conception of honour and of responsibility. The conclusion of *A Doll's House* was violently and continuously discussed through the length and breadth of Europe, and to the situation of Nora Helmer is probably due more than to anything else the long tradition that Ibsen is "immoral." He braved convention still more audaciously in *Ghosts* (1881), which is perhaps the most powerful of the series of plays in which Ibsen is occupied in diagnosing the diseases of modern society. It was received in Norway with a tumult of ill-will, and the author was attacked no less venomously than he had been twenty years before. Ibsen was astonished and indignant at the reception which was given to *Ghosts*, and at the insolent indifferentism of the majority to all ideas of social reform. He wrote, more as a pamphlet than as a play, what is yet one of the most effective of his comedies, *An Enemy of the People* (1882). Dr Stockmann, the hero of that piece, discovers that the drainage system of the bathing-station on which the little town depends is faulty, and the water impure and dangerous. He supposes that the corporation will be grateful to have these deficiencies pointed out; on the contrary, they hound him out of their midst as an "enemy of the people." In this play occurs Ibsen's famous and typical saying, "a minority may be right—a majority is always wrong." This polemical comedy seemed at first to be somewhat weakened by the personal indignation which runs through it, but it has held the stage. Ibsen's next drama, *The Wild Duck* (1884), was written in singular contrast with the zest and fire which had inspired *An Enemy of the People*. Here he is squalid and pessimistic to a degree elsewhere unparalleled in his writings; it is not quite certain that he is not here guilty of a touch of parody of himself. The main figure of the play is an unhealthy, unlucky enthusiast, who goes about making hopeless mischief by exposing weak places in the sordid subterfuges of others. This drama contains a figure, Hjalmar Ekdal, who claims the bad pre-eminence of being the meanest scoundrel in all drama. *The Wild Duck* is the darkest, the least relieved, of Ibsen's studies of social life, and his object in composing it is not quite obvious. With *Rosmersholm* (1885) he rose to the height of his genius again; this is a mournful, but neither a pessimistic nor a cynical play. The fates which hang round the contrasted lives of Rosmer and Rebecca, the weak-willed scrupulous man and the strong-willed unshrinking woman, the old culture and the new, the sickly conscience and the robust one, create a splendid dramatic antithesis. Since that time, Ibsen has written a series of dramas, of a more and more symbolical and poetic character; the earliest of these was the mystical *The Lady from the Sea* (1888). At Christmas 1890 he brought out *Hedda Gabler;* two years later *The Master-*

builder, in which many critics see the highest attainment of his genius; at the close of 1894 *Little Eyolf;* at Christmas 1896 *John Gabriel Borkman;* and in January 1900 *When We Dead Awaken.* On the occasion of his seventieth birthday (20th March 1898), Ibsen was the recipient of the highest honours from his own country and of congratulations and gifts from all parts of the world. A colossal bronze statue of him was erected outside the new National Theatre in September 1899. No recent writer belonging to the smaller countries of Europe has had so widely spread a fame as that of Ibsen, and although the value of his dramatic work is still occasionally contested—at least in England—it has received the compliment of vivacious discussion in every part of the world. There would, perhaps, have been less violence in this discussion if it had been perceived that the author does not pose as a moral teacher, but as an imaginative investigator. He often and with much heat has insisted that he is not called upon as a poet to suggest a remedy for the diseases of society, but to diagnose them. In this he is diametrically opposed to Tolstoi, who admits that he writes his books for the healing of the nations. If the subjects which Ibsen treats, or some of them, are open to controversy, we are at least on firm ground in doing homage to the splendour of his art as a playwright. He has re-introduced into modern dramatic literature something of the velocity and inevitability of Greek tragic intrigue. It is very rarely that any technical fault can be found with the architecture of his plots, and his dialogue is the most lifelike that the modern stage has seen. His long apprenticeship to the theatre in his early days was no doubt of immense service to him in this respect. In every country, though least perhaps in England, the influence of Ibsen has been marked in the theatrical productions of the younger school. Even in England, on the rare occasions when his dramas are acted, they awaken great interest among all intelligent playgoers.

Ica, a coast department of Peru. It has an area of 6295 square miles, and the population in 1896 was 90,962, or 14 to the square mile. It is divided into two provinces, Chindia and Ica. The vine is extensively cultivated, in addition to sugar-cane, tobacco, and rice, and the mineral waters have some repute. There is a railway from Ica, the capital of the province and department (about 12,000), to Pisco.

ICELAND.

Geography and Statistics.

ICELAND has an area of 40,437 square miles. Its length is 298 miles, and breadth 194 miles. The most extensive development of the coast-line is on the north-west, where a peninsula, diversified by a great number of fjords, projects outwards from the main portion of the island. The total length of the coast-line is about 3730 miles, of which approximately one-third belongs to the north-west peninsula. The great bays on the west of the island (Faxaflói and Breiðifjörður), as well as the many bays on the north, which are separated from one another by rocky promontories, appear to owe their origin to subsidences of the surface; whereas the fjords of the north-west peninsula, which make excellent harbours, and those of the east coast, seem to be the result chiefly of erosion.

The Tablelands.—Iceland is a plateau or tableland, built up of volcanic rocks of older and younger formation, and pierced on all sides by fjords and valleys. As compared with the tableland, the lowlands have a relatively small area, namely, one-fourteenth of the whole; but, on the other hand, they are of vastly the greater importance, for the low-lying coasts and valleys are almost the only parts of the island which are inhabited. In consequence of the rigour of its climate, the central tableland is absolutely uninhabitable. At the very outside, not more than one-fourth of the area of Iceland is inhabited; the rest consists of elevated deserts, lava streams, and glaciers. The north-west peninsula is separated from the main mass of the island by the bays Hunaflói and Breiðifjörður, so that there are really two tablelands, a larger and a smaller. The isthmus which connects the two is only 4¼ miles across, but has an altitude of 748 feet above sea-level. The mean elevation of the north-west peninsula is 2000 feet. The numerous fjords and glens which cut into it from all sides are shut in by precipitous walls of basalt, which plainly shows that they have been formed by erosion right through the mass of the plateau. The surface of this tableland is also bare and desolate, being covered with gravel and fragments of rock. There is scarcely a vestige of vegetation; but here and there are large straggling snowfields, the largest being Gláma and Drangajökull, on the culminating points of the plateau. The only districts which are inhabited are the shores of the fjords, where grass grows capable of supporting sheep; but a large proportion of the population gain their livelihood by fishing. The other and larger tableland, which constitutes the substantial part of Iceland, reaches its culminating point in the south-east, in the gigantic snowfield of Vatnajökull, which covers an area of 3300 square miles. The axis of highest elevation of Iceland stretches from north-west to south-east, from the head of Hvammsfjörður to Hornafjörður, and from this water-parting the rivers descend on both sides. The crest of the water-parting is crowned by a chain of snow-capped mountains, separated by broad patches of lower ground. In fact, they are really a chain of minor plateaux, which rise to an altitude of from 4500 to 6250 feet above sea-level and 2000 to 3000 feet above the tableland itself. In the extreme east is Vatnajökull, which is separated from Tungnafellsjökull by Vonarskard (3300 feet). Between Tungnafellsjökull and Hofsjökull lies the broad depression of Sprengisandur (2130 feet). Between Hofsjökull—still going north-west—and the next snow-capped mountain, Langjökull, lies Kjölur (2000 feet); and between Langjökull and Eiriksjökull, Flosaskard (2630 feet). To the north of the *jöklar* last mentioned there are a number of lakes, all well stocked with fish. Numerous valleys or glens penetrate into the tableland, especially on the north and east, and between them long mountain spurs, sections of the tableland which have resisted the action of erosion, thrust themselves out towards the sea. Of these the most considerable is the mass crowned by Mýrdalsjökull, which stretches towards the south. The interior of the tableland consists for the most part of barren, grassless deserts, the surface being covered by gravel, loose fragments of rock, lava, driftsand, volcanic ashes, and glacial detritus.

The *Lowlands* cover, as already mentioned, a relatively small area. With the exception of the lower parts of the larger glens, there are no lowlands on the north and east; they are confined entirely to the south and west. The south coast is flat next the sea; but immediately underneath Vatnajökull there is merely a strip of gravel and sand, brought down and deposited by the glacial streams.

The most extensive low-lying plain of Iceland is that which lies between Mýrdalsjökull and Reykjanes, with an area of about 1550 square miles. In its lowest parts this plain barely keeps above sea-level, but it rises gradually towards the interior, finally terminating in a ramification of valleys. Its maximum altitude is attained in 381 feet, near Geysir. On the west of Hekla this lowland plain connects by a regular slope directly with the tableland, to the great injury of its inhabited districts, which are thus exposed to the clouds of pumice dust and drift-sand that cover large areas of the interior. In this way a considerable portion of this region has been devastated by the north-east storms. Nevertheless the greater part of this lowland plain produces good grass, and is relatively well inhabited. The plain is drained by three rivers—Markarfljót, Thjórsá, and Oelfusá—all of large volume, and numerous smaller streams. Towards the west there exist a number of warm springs. There is another lowland plain around the head of Faxaflói, nearly 400 square miles in extent. This, like the former plain, is encircled by mountains. As a rule the surface of this second plain is very marshy. Several dales or glens penetrate the central tableland; the eastern part of this lowland is called Borgarfjörður, the western part Mýrar.

Glaciers.—An area of no less than 5170 square miles is covered with snowfields and glaciers (*jöklar*). This extraordinary development of ice and snow is due to the raw, moist climate, the large rainfall, and the low summer temperature. The snow-line varies greatly in different parts of the island, its range being from 1300 to 4250 feet. It is highest on the tableland, on the north side of Vatnajökull, and lowest on the north-west peninsula, to the south of North Cape. Without exception the great névés of Iceland belong to the interior tableland. Interiorly they consist of slightly rounded domes or billowy snowfields of vast thickness. In external appearance they bear a closer resemblance to the glaciers of the Polar Regions than to those of the Alps. The largest snowfields are Vatnajökull (3280 square miles), Hofsjökull (520), Langjökull (500), and Mýrdalsjökull (390). The glaciers which stream off from these snowfields are often of vast extent, *e.g.*, the largest glacier of Vatnajökull has an area of 150 to 200 square miles, but the greater number are of course small. Altogether, at the present time more than 124 glaciers are known in Iceland. It is on the south side of Vatnajökull that they descend lowest; the lower end of Breidamerkurjökull was in the year 1894 only 30 feet above sea-level. The glaciers of the north-west peninsula also descend very nearly to sea-level. The great number of streams of large volume is due to the moist climate and the abundance of glaciers, and the milky white or yellowish-brown colour of their waters is due to the glacial clays. The majority of them change their courses very often, as well as vary greatly in volume; frequently they are impetuous torrents, hampered by numerous waterfalls. Iceland also possesses a great number of lakes, the largest being Thingvallavatn and Thorisvatn, each about 27 square miles in area. Mývatn, in the north, is well known from the natural beauty of its surroundings. Above its surface tower a great number of volcanoes and several craters, and its waters are alive with waterfowl, a multitude of ducks of every species breeding on its islands. The lakes of Iceland owe their origin to different causes, some being due to glacial erosion, others to volcanic subsidence. Mývatn fills a depression between lava streams, and has a depth of not more than 8¾ feet. The group of lakes called Fiskivötn (or Veidivötn), which lie in a desolate region to the west of Vatnajökull, consist for the most part of crater lakes. The groups of lakes which lie north-west from Langjökull occupy basins formed between ridges of glacial gravel; and in the valleys numerous lakes are found at the backs of the old moraines.

Geology.—Iceland is built up almost entirely of volcanic rocks, none of them older, however, than the middle of the Tertiary period. The principal varieties are basalt and palagonitic breccias, the former covering two-thirds of the entire area, the latter the remaining one-third. Compared with these two systems, all other formations have but an insignificant development. The palagonitic breccias, which stretch in an irregular belt across the island, are younger than the basalt. In the north-west, north, and east the coasts are formed of basalt, and rise in steep, gloomy walls of rock to altitudes of 3000 feet and more above the level of the sea. Deposits of clay, with remains of plants of the Tertiary period, lignite, and tree-trunks pressed flat, which the Icelanders call *surtarbrandur*, occur in places in the heart of the basalt formation. The region in which these fossiliferous strata are developed in greatest thickness is the north-west peninsula. Indeed, in some few places well-marked impressions of leaves and fruit have been discovered, proving that in Tertiary times Iceland possessed extensive forests, and its annual mean temperature must have been at least 48·2° Fahr., whereas the present mean is 35·6°. The palagonitic breccias, which attain their greatest development in the south of the island and on the tableland, consist of reddish, brown, or yellowish rocks, tuffs and breccias, belonging to several different groups or divisions, the youngest of which seems to be of a date subsequent to the Glacial epoch. All over Iceland, in both the basalt and breccia formations, there occur small intrusive beds and dykes of liparite, and as this rock is of a lighter colour than the basalt, it is consequently visible from a distance. In the south-east of the island, in the parish of Lón, there exist a few mountains of gabbro, a variety of rock which does not occur in any other part of Iceland. In the neighbourhood of Húsavik in the north there have been found marine deposits containing a number of marine shells; they belong to the Red Crag division of the Pliocene. In the middle of Iceland, where the geological foundation is tuff and breccias, large areas are buried under ancient outflows of lava, which bear evidences of glacial scratching. These lava streams, which are of a doleritic character, flowed before the Glacial age, or during its continuance, out of lava cones with gigantic crater openings, such as may be seen in some places even at the present day. During the Glacial epoch the whole of Iceland was covered by a vast sheet of inland ice, except for a few small isolated peaks rising here and there along its outer margins. This ice-cap had on the tableland a thickness of 2300 to 2600 feet. Rocks scored by glacial ice and showing plain indications of striation, together with thousands of erratic blocks, are found scattered all over Iceland. Signs of the coast having receded subsequent to the Glacial epoch are very common all round the island, especially on the north-west peninsula. There we find strikingly developed marine terraces of gravel, shore lines, and surf beaches marked on the solid rock. In several places, too, there are traces of shells; and sometimes skeletal remains of whales and walruses, as well as ancient driftwood, have been discovered at tolerable distances from the present coast. The ancient shore-lines occur at two different altitudes. Along the higher, 230 to 260 feet above the existing sea-level, shells have been found which are characteristic of high Arctic latitudes and no longer exist in Iceland; whereas on the lower shore-line, 100 to 130 feet, the shells belong to species which occur amongst the coast fauna of the present day.

Volcanoes.—Iceland is one of the most volcanic regions

on the face of the earth; volcanic activity has gone on continuously from the first formation of the island in the Tertiary period down to the present time. So far as is known, there have in historic times been eruptions from twenty-five volcanic vents. Altogether 107 volcanoes are known to exist in Iceland, with thousands of craters, great and small. From all these there has issued a vast quantity of lava. The lava-streams which have flowed out since the Glacial epoch now cover an area of 4650 square miles. They are grouped in dense masses around the volcanoes from which they have flowed. The majority of them are the accumulated result of several outflows which have taken place at different periods; but the bulk of the lava dates from outbreaks which occurred in prehistoric times. The largest volume of lava which has issued at one outflow within historic times is the stream which came from the craters of Laki at Skaptá. This belongs to the year 1783, and covers an area of 218 square miles, and amounts to a volume represented by a cube each of whose sides measures 7½ miles. The largest unbroken lava-field in Iceland is Odaðahraun, upon the tableland north from Vatnajökull (2000 to 4000 feet above sea-level). It is the accretion of countless eruptions from over twenty volcanoes, and covers an area of 1300 square miles (or, including all its ramifications and minor detached streams, 1700 square miles), and its volume would fill a cube measuring 134 miles in every direction. As regards their superficies, the lava-streams differ greatly. Sometimes they are very uneven and jagged (*apalhraun*), consisting of blocks of lava loosely flung together in the utmost confusion. The big lava-fields, however, are composed of vast sheets of lava, ruptured and riven in divers ways (*helluhraun*). The smooth surface of the viscous billowy lava is further diversified by long twisted "ropes," curving backwards and forwards up and down the undulations. Moreover, there are gigantic fissures, running for several miles, which have been caused by subsidences of the underlying sections. The best-known fissure of this character is Almannagjá at Thingvellir. On the occasion of outbreaks the fine ashes are scattered over a large portion of the island, and sometimes carried far out across the Atlantic. After the eruption of Katla in 1625 the ashes were blown as far as Bergen in Norway, and when Askja was in eruption in 1875 a rain of ashes fell on the west coast of Norway 11 hours 40 minutes later and at Stockholm 15 hours afterwards. The volcanic ash frequently proves extremely harmful, in that it destroys the pastures, so that the sheep and cattle die of hunger and disease. The outbreak of Laki in 1783 occasioned the loss of 11,500 cattle, 28,000 horses, and 190,500 sheep—that is to say, 53 per cent. of all the cattle there were in the island, 77 per cent. of the horses, and 82 per cent. of the sheep. After that the island was visited by a famine, which destroyed 9500 people, or one-fifth of the total population.

The Icelandic volcanoes may be divided into three classes: (1) cone-shaped, like Vesuvius, built up of alternate layers of ashes, scoriæ, and lava; (2) cupola-shaped, with an easy slope and a vast crater opening at the top—these shield-shaped cupolas are composed entirely of layers of lava, and their inclination is seldom steeper than 7°–8°; (3) long chains of craters running close alongside a fissure in the ground. For the most part the individual craters are low, generally not exceeding 300 and 500 feet. These crater chains are both very common and often very long. The chain of Laki, which was formed in 1783, extends to 20 miles, and embraces about one hundred separate craters of different sizes. Sometimes, however, the lava-streams are vomited straight out of gigantic fissures in the earth without any crater being formed. Many of the Icelandic volcanoes are during their periods of quiescence covered with snow and ice. Then when an outbreak occurs the snow and ice melt, and in that way they sometimes give rise to serious catastrophes (*jökulhlaup*), through large areas of the country being suddenly inundated by great floods of water, which bear masses of ice floating on their surface. Katla caused very serious destruction in this way by converting several cultivated districts into barren wastes. In the same way in the year 1362 Oeræfajökull, the loftiest mountain in Iceland (6424 feet), annihilated two entire parishes by sweeping forty farms, together with their inhabitants and live stock, bodily into the ocean. The best-known of the volcanoes is Hekla, which has been in eruption eighteen times within the historic period, the last in 1845. Katla during the same period has been active thirteen times, the last occasion being in 1860. The largest volcano is Askja, situated in the middle of the lava-field of Odaðahraun. Its crater measures 34 square miles in area, and its latest outburst was in 1875. At Mývatn there are several volcanoes, which were particularly active in the years 1724–30. On several occasions there have been volcanic outbreaks under the sea outside the peninsula of Reykjanes, islands appearing above the waves and afterwards disappearing again. The crater chain of Laki has only been in eruption once in historic times, namely, the violent and disastrous outbreak of 1783. Iceland, however, possesses no constantly active volcano, such as, *e.g.*, Stromboli. There are often long intervals between the successive outbreaks, and the outbreaks are wont to be exceedingly violent. Indeed, many of the volcanoes, and this is especially true of the chains of craters, have only vented themselves in a solitary outburst.

Earthquakes are a phenomenon of frequent occurrence, especially in the districts which are peculiarly volcanic. Historical evidence goes to show that they are closely associated with three naturally defined regions—(1) the region between Skjálfandi and Axarfjörður in the north, where violent earth tremblings are extremely common; (2) at Faxaflói, where minor vibrations are frequent; (3) the southern lowlands, between Reykjanes and Mýrdalsjökull, have frequently been devastated by violent earthquake shocks, with great loss of property and life, *e.g.*, on 14th–16th August 1784, when 92 farmsteads were totally destroyed, and 372 farmsteads and 11 churches were seriously damaged; and again in August and September 1896, when another terrible earthquake visited this region, completely destroying 161 farmsteads and doing injury to 155 others. Hot springs are found in every part of Iceland, both singly and in groups; they are more particularly numerous in the western portion of the southern lowlands, where amongst others is the famous Geysir. Sulphur springs and boiling mud lakes are also general in the volcanic districts; and in places there are carbonic acid springs, these more especially on the peninsula of Snæfellsnes, north of Faxaflói.

Climate.—Considering its high latitude and situation, Iceland has a relatively mild climate. The meteorological conditions vary, however, greatly in different parts of the island. In the south and east the weather is generally changeable, stormy, and moist; whilst on the north the rainfall is less. The climate of the interior tableland approximates to the continental type, the thermometer sometimes falling to the levels of extremely bitter cold. The mean temperature of the year is 37·2° Fahr. in Stykkishólmur on Breiðifjörður, 38·3° at Eyrarbakki in the south of Iceland, 41° at Vestmannaeyjar, 36° at Akureyri in the north, 36·7° on Berufjörður in the east, and 30·6° at Mödrudalur on the central tableland. The range is great not only from year to year, but also from

month to month. For instance, at Stykkishólmur the highest annual mean for March was 39·7°, and the lowest 8°, during a period of thirty-eight years. Iceland lies contiguous to that part of the north Atlantic in which the shifting areas of low pressure prevail, so that storms are frequent and the barometer is seldom firm. The barometric pressure at sea-level in the south-west of Iceland during the period 1878–1900 varied between 30·8 and 27·1 inches. The climate of the coasts, which is closely dependent upon the oceanic currents, is relatively mild in summer, but tolerably cold in winter. The winter means of the north and east coasts average 31·7° and 31·3° Fahr. respectively; the summer means, 42·8° and 44·6°; and the means of the year, 33·1° and 35·6°. On the other hand, the winter means of the south and west coasts average 32° and 31·7° respectively; the summer means, 48·2° and 50°; the annual means, 37·4° and 39·2°. The rainfall on the south and east coasts is considerable, *e.g.*, at Vestmannaeyjar, 49·4 inches in the year; at Berufjörður, 43·6 inches. On the west coast it is less, *e.g.*, 24·3 inches at Stykkishólmur; but least of all on the north coast, being only 14·6 inches on the island of Grímsey, which lies off that coast. Mist is commonly prevalent on the east coast; at Berufjörður there is mist on no less than 212 days in the year. The south and west coasts are washed by the Gulf Stream, and the north coast by an Arctic current, which frequently brings with it a quantity of drift-ice, and thus exercises a considerable effect upon the climate of the island; sometimes it effectually blocks the north coast in the summer months. On the whole, during the 19th century, the north coast has been free from ice on an average of one year in every four or five.

Flora.—The vegetation presents the characteristics of an Arctic-European type, and is tolerably uniform throughout every part of the island, the differences even on the tableland being but slight. At present 435 species of Phanerogams and Vascular Cryptogams are known; the lower Orders have been but little investigated. The grasses are of the greatest importance to the inhabitants, for upon them they are dependent for the summer and winter keep of their live stock. Heather is also extensively prevalent, and plays a prominent part in the feeding of the sheep. The development of forest trees is insignificant. Birch woods still exist in a good many places, especially in the warmer valleys, which penetrate considerable distances inland; but the trees are very short, scarcely attaining to more than 3 to 10 feet in height. In a few places, however, they reach 13 to 20 feet; and the highest birch-tree in Iceland (at Hallormstadaskógur in East Iceland) reaches 28 feet. A few mountain ash or rowan trees (*Sorbus aucuparia*) are found growing singly here and there, and attain to 30 feet in height. Willows are also pretty general, the highest in growth being *Salix phyllicifolia*, 7 to 10 feet.

Fauna.—The Icelandic fauna is of a sub-Arctic type. But while the species are few, the individuals are often numerous. The land mammals are very poorly represented; and it is doubtful whether any species of those that do exist is indigenous. The polar bear is an occasional visitant, being brought to the coast by the Greenland drift-ice. Foxes are common; mice and the brown rat have been introduced, though one mouse variety is possibly indigenous. Reindeer were introduced in 1770. The marine mammalia are very numerous. The walrus is now seldom seen, although in prehistoric times it was very common. There are numerous species of seals; and the seas abound in whales, and a considerable whaling industry thrives on the north-west coast. Of birds there are over 100 species, more than one-half of them being aquatic. In the interior the whistling swan is common, and numerous varieties of ducks are found in the lakes. The eider duck, which breeds on the islands of Breiðifjörður, is a source of livelihood to the inhabitants, as are also the many kinds of sea-fowl which breed on the sea-cliffs. Iceland possesses neither reptiles nor batrachians. The fish fauna is abundant in individuals, some sixty-eight species being found off the coasts. The cod fisheries are amongst the most important in the world. Large quantities of herring, plaice, and halibut are also taken. Many of the rivers abound in salmon, and trout are plentiful in the lakes and streams.

Population and Occupations.—The census of 1890 gave a total population of 70,927, and this number had by the end of 1899 increased to 76,383. The increase during the 19th century was 27,000; to whom must be added at least 15,600 more, who have emigrated to America, chiefly to Manitoba, since 1872. The principal occupation of the Icelanders is breeding of cattle, more particularly the breeding of sheep, although during the last few years the fishing industries have come rapidly to the front. In 1850, 82 per cent. of the population were dependent upon cattle-breeding and 7 per cent. upon fishing; in 1890 the numbers were 64 per cent. and 18 per cent. respectively. Agriculture is, however, not now practised in Iceland; all bread-stuffs are imported. In ancient times barley was grown in some places, but it never paid for the cost of cultivation. The moist insular climate and the coolness of the summers are inimical to the cultivation of crops and the growth of forests. The breeding of cattle has declined in importance. In 1703 there were 35,860 head of cattle; in 1898, 21,982 head. On the other hand, the number of sheep has increased from 278,994 in 1703 to 735,442 in 1898. In the latter year there were 44,134 horses, relatively a large number, but then all travelling is done on horseback, and by the same means all goods are conveyed. Formerly gardening was of no importance, but considerable progress has been made in this branch of late years, especially in the cultivation of potatoes and turnips. In 1895 the harvest amounted to 67,400 bushels of potatoes and 61,750 bushels of turnips. Fruit-trees will not thrive; but black and red currants and rhubarb are grown, the last-named doing excellently well. Iceland possesses four agricultural schools, one agricultural society, and small agricultural associations in nearly every district. The fisheries give employment to about 12,000 people. For the most part the fishing is carried on from open boats, notwithstanding the dangers of so stormy a coast, especially in winter, and many lives are lost every year. But during recent years the fishermen have begun to use larger decked vessels, and these boats are increasing in number every season. In summer the waters are visited by a great number of foreign fishermen, inclusive of about 300 fishing-boats from French ports, manned by about 5000 men, as well as in the last years by fishing-boats from the Faröes and Norway and steam trawlers from England. Excellent profit is made in certain parts of the island from the herring fishery; this is especially the case on the east coast. Marine insurance societies and a school of navigation have been founded at Reykjavik. The export of fish and fish products has greatly increased. For instance, in 1849–55 the annual average exported was 1480 tons; in 1891–94 it was 10,800 tons, valued at £215,000; and in 1899 amounted to 11,339 tons and 68,079 barrels of oil, valued at £276,596.

Commerce.—From the first colonization of the island down to the 14th century the trade was in the hands of native Icelanders and Norsemen; in the 15th century it was chiefly in the hands of the English, in the 16th of

Germans from the Hanse towns. From 1602 to 1786 commerce was a monopoly of the Danish Government; in the latter year it was declared free to all Danish subjects, and in 1854 free to all nations. Since the year 1874, when Iceland obtained her own administration and the arrangement of her own finances, both the general comfort of the people and the commerce have increased considerably. The total value of the imports and exports together amounted in 1849 to not more than £170,000; in the years 1881–85 the annual average value of the imports alone amounted to £340,000, and of the exports to £310,000; whilst in 1891–95 the imports averaged £356,000, and the exports £340,000. In the year 1899 the imports were valued at £458,500, and the exports at £426,900, or a total of £885,400. That is to say, since 1849 the value of the aggregate trade has increased by £715,400, and is now more than five times greater than when free trade was introduced. The principal native products exported are live sheep, horses, salt meat, wool and woollen wares, and hides, to which must be added the fish products—cod, train-oil, herring, and salmon —and eiderdown feathers, &c. The imports consist principally of cereals and flour, coffee, sugar, ale, wines and spirits, tobacco, manufactured wares, iron and metal wares, timber, salt, coal, &c. In the year 1898 there were in Iceland 204 merchants' businesses, of which 156 belonged to Icelanders, and 48 to Danes and foreigners; in addition several co-operative societies buy considerable quantities of goods in England through commission agents. In 1899 the shipping which entered at Icelandic ports was represented by 380 vessels of 70,359 tons (199 steamships of 54,228 tons and 181 sailing vessels of 16,131 tons); of which 82 of 18,357 tons came from Denmark, 179 of 30,000 tons from Great Britain, and 69 of 10,725 tons from Norway. The money, weights, and measures in use are the same as in Denmark. The National Bank in Reykjavik issues bank-notes, though not beyond £41,670 in value.

Communications.—In so sparsely inhabited a country the means of communication have always been primitive. All land journeys are made on horseback, and in the remoter parts all goods have to be transported by the same means. Throughout the greater part of the island there exist no proper roads even in the inhabited districts, only bridle-paths. In the uninhabited districts there are not even bridle-paths. Nevertheless a good deal has been done to improve such paths as there are, and even several miles of driving roads have been made, more particularly in the south. Since 1888 many bridges have been built; previous to that year there were none at all. The larger rivers have been spanned by iron swing bridges, as, for example, Oelfusá and Thjórsá, and Blanda is now crossed by a fixed iron bridge. Great progress has also been made in the steamboat services round the coasts and with foreign countries. Postal connexion is maintained with Denmark by steamboats, which sail from Copenhagen eighteen times a year, and put in at Leith on the way. Besides, steamers go all round the island, touching at nearly every port.

Religion.—The Icelanders are Lutherans. For ecclesiastical purposes the island is divided into 20 deaneries and 142 parishes, and the affairs of each ecclesiastical parish are administered by a parish council, and in each deanery by a district (*hjerað*) council. When a living falls vacant, the governor-general of the island, after consultation with the bishop, selects three candidates, and from these the congregation chooses one, the election being subsequently confirmed by the governor-general. In the case of certain livings, however, the election requires confirmation by the Crown. In 1847 a theological seminary was founded at Reykjavik, and there the majority of the Icelandic ministry are educated; some, however, are graduates of the University of Copenhagen.

The *public health* has shown great improvement; the death-rate of little children has in especial diminished very appreciably. This improvement is due to greater cleanliness, better dwellings, better nourishment, and the increase in the number of doctors and midwives, who are now scattered all over the country, whereas formerly there was scarcely a doctor to be found from one end of the island to another. A new asylum for leprosy has been erected at Laugarnes near Reykjavik. There is a medical school at Reykjavik, opened in 1876. The general sanitary affairs of the island are under the control of a chief surgeon (national physician), who lives in Reykjavik, and also has the superintendence over the doctors and the medical school. There are at the present time twenty permanently appointed district surgeons, besides sixteen assistant surgeons, a state oculist, four small hospitals, and four dispensaries. Midwives are required to attend a course of lectures at the medical school.

Administration and Finances.—There was no change of any importance in the administrative relations during the last twenty-five years of the 19th century. But in 1902 it was arranged that the minister for Iceland should transfer his office from Copenhagen to Reykjavik. Iceland has her own budget, the Althing having, by the constitution of 1874, acquired the right to vote its own supplies. The Althing only meets every other year, and the budget is consequently passed for two years at once. In the financial period 1896–97 the total income was £67,200, the expenditure £67,300. There is a national reserve fund of about £60,000, but no public debt; nor is there any contribution for either military or naval purposes. Iceland has her own customs service, but the only import duties levied are upon spirits, tobacco, coffee, and sugar, and in each case the duties are fairly low. During recent years one-quarter of the national income has been spent upon the means of communication—subventions to the steamboat service round the coasts, and for the building of bridges and the making of roads. In Reykjavik there is a national bank, and there are numerous small savings banks in various parts of the island.

Education.—Notwithstanding that there are still only a few elementary schools in the towns, in the fishing villages, and in certain more densely inhabited parts of the island, education is pretty widespread amongst the people. Very often the children are instructed at home; in some places by peripatetic teachers. It is incumbent upon the clergy to see that all children are taught to read, and write, and "sum." The people are great readers; considering the number of the inhabitants, books and periodicals have a very extensive circulation. At the present time eighteen newspapers are issued (once and twice a week), besides several journals. Iceland has always been distinguished for her native literature. At Reykjavik there are a Latin school, a medical school, and a theological school; at Mödruvellir and Hafnarfjörður, modern high schools (*realschulen*); and in addition to these there are four agricultural schools, a school of navigation, and three girls' schools. The largest collection of books is the national library at Reykjavik, containing some 40,000 volumes and 3000 MSS. At the same place there is also a valuable archæological collection. Amongst the learned societies may be mentioned the Icelandic Literary Society (*Bokmentafjelag*) and the Society of the Friends of the People, as well as the Archæological Society of Reykjavik.

Towns.—There are several small towns scattered along the coasts. The largest is Reykjavik on Faxaflói, with

6700 inhabitants (1900), the capital of the island, and the place of residence of the governor-general and the bishop. There, too, the Icelandic Parliament (Althing) meets; and there, further, are the principal public institutions of the island (library, schools, &c.). The town is adorned by a statue to Thorvaldsen, the famous sculptor, who was of Icelandic descent. The remaining towns embrace Isafjörður (1000) on the north-west peninsula, Akureyri (1000) on the north, and Seydisfjörður (800) in the east. The total urban population was 14,705 inhabitants in 1899. (TH. T.)

LITERATURE.

The literature of Iceland since 1874 has been in a more flourishing state than ever before since the 13th century. Lyrical poetry is by far the largest and the most interesting portion of it. The great influence of Jónas Hallgrímsson (1807–1845) is still felt, and his school was the reigning one up to the end of the 19th century, although then a change seemed to be in sight. The most successful poet of this school is Steingrímr Thorsteinsson (born 1830). He is specially famous for his splendid descriptions of scenery (*The Song of Gilsbakki*), his love-songs, and his sarcastic epigrams. As a translator he has enriched the literature with *The Arabian Nights*, *Sakuntala*, *King Lear*, and several other masterpieces of foreign literature. Equal in fame is Matthías Jochumsson (born 1835), who, following another of Jónas Hallgrímsson's many ways, has successfully revived the old metres of the classical Icelandic poets, whom he resembles in his majestic, but sometimes too gorgeous, language. He is as an artist inferior to Steingrímr Thorsteinsson, but surpasses him in bold flight of imagination. He has successfully treated subjects from Icelandic history (*Grettisljóð*, a series of poems about the famous outlaw Grettir). His chief fault is a certain carelessness in writing; he can never write a bad poem, but rarely a poem absolutely flawless. He has translated Tegnér's *Frithiofs Saga*, several plays of Shakespeare, and some other foreign masterpieces. The great religious poet of Iceland, Hallgrímr Pétursson, has found a worthy successor in Valdimar Briem (born 1848), whose *Songs of the Bible* are deservedly popular. He is like Matthías Jochumsson in the copious flow of his rhetoric; some of his poems are perfect both as regards form and contents, but he sometimes neglects the latter while polishing the former. An interesting position is occupied by Benedict Gröndal (born 1826), whose travesties of the old romantic stories,[1] and his truly Aristophanic drama *Gandreiðin* ("The Magic Ride") about contemporary events, are among the best satirical and humorous productions of Icelandic literature. Most of his works belong, however, to the period before 1874; after that time he is chiefly known as a miscellaneous writer.

Influenced by Jónas Hallgrímsson with regard to language and poetic diction, but keeping unbroken the traditions of Icelandic mediæval poetry maintained by Sigurðr Breiðfjörð (1798–1846), is another school of poets, very unlike the first. In the middle of the 19th century this school was best represented by Hjálmar Jónsson from Bóla (1796–1875), a poor farmer without any education to speak of, but endowed with great poetical talents, and the author of satirical verses not inferior to those of Juvenal both in force and coarseness. In the last decades of the 19th century this school produced two poets of a very high order, both distinctly original and Icelandic, and comparatively free from any foreign influence. One is Páll Olafsson (born 1827). His songs are mostly written in the mediæval quatrains (*ferskeytla*), and are generally of a humorous and satirical character; his convivial songs are known by heart by every modern Icelander; and although some of the poets of the present day are more admired, there is none who is more loved by the people at large. The other is Þorsteinn Erlingsson (born 1858). His exquisite satirical songs, in an easy and elegant, but still manly and splendid language, have raised much discussion. Of his poems may be mentioned *The Oath*, a series of most beautiful ballads, with a tragical love-story of the 17th century as their base, but with many and happy satirical allusions to modern life; *Jörundr*, a long poem about the convict king, the Danish pirate Jörgensen, who nearly succeeded in making himself the master of Iceland, and *The Fate of the Gods* and *The Men of the West* (the Americans), two poems which, with their anti-clerical and half-socialistic tendencies, have caused strong protests from some of the orthodox Lutheran clergy. Near to this school, but still standing apart, is Grímur Thomsen (born 1820).

In the beginning of the 'eighties a new school arose—having its origin in the colony of Icelandic students at the University of Copenhagen. They had all attended the lectures of Georg Brandes, the great reformer of Scandinavian literature, and, influenced by his literary theories, they chose their models in the realistic school, which then gradually was becoming the reigning one in all the Scandinavian countries. This school is very dissimilar from the half-romantic school of Jónas Hallgrímsson; it is nearer the national Icelandic school represented by Páll Olafsson and Þorsteinn Erlingsson, but differs from those writers by introducing foreign elements hitherto unknown in Icelandic literature, and—especially in the case of the prose-writers—by imitating closely the style and manner of some of the great Norwegian novelists. Their influence brought the Icelandic literature into new roads, and it is interesting to see how the tough Icelandic element gradually assimilates the foreign. Of the lyrical poets, Hannes Hafsteinn (born 1861) is by far the most important. In his splendid ballad, *The Death of Skarphedinn*, and in his beautiful series of songs describing a voyage through some of the most picturesque parts of Iceland, he is entirely original; but in his love-songs, beautiful as many of them are, a strong foreign influence can be observed. Among the innovations of this poet we may note a predilection for new metres, sometimes adopted from foreign languages, sometimes invented by himself, a thing practised rarely and generally with small success by the Icelandic poets, who as a rule are extremely conservative in that respect, and generally keep to the metres used by their predecessors.

No Icelandic novelist has as yet equalled Jón Thóroddsen (1819–1868). The influence of the realistic school has of late been predominant. The most distinguished writer of that school has been Gestur Pálsson (1852–1891), whose short stories, with their sharp and biting satire, have produced many imitations in Iceland. The best are *A Home of Love* and *Captain Sigurd*. Jónas Jónasson (born 1856), a clergyman of northern Iceland, has, in a series of novels and short stories, given accurate, but somewhat dry, descriptions of the more gloomy sides of Icelandic country life. His best novel is *Randíðr from Hvassafell*, a historical novel of the Middle Ages. Besides these we may mention Torfhildur Hólm, one of the few ladies who have distinguished themselves in Icelandic literature. Her novels are mostly historical.

The drama is still in its infancy, but the last decade of the 19th century saw the establishment of a permanent theatre at Reykjavík. The poet Matthías Jochumsson has written several dramas, but their chief merits are lyrical. The most successful of Icelandic dramatists as yet is Indriði Einarsson, whose plays, chiefly historical, in spite

[1] *E.g.*, "The Battle of the Plains of Death," a burlesque on the battle of Solferino.

of excessive rhetoric, are very interesting, and possess a true dramatic spirit.

In geography and geology Þorvaldr Thoroddsen has acquired a European fame for his researches and travels in Iceland, especially in the rarely-visited interior. Of his numerous works in Icelandic, Danish, and German, we may mention the *History of Icelandic Geography*, a monumental work. In history Páll Melsteð's (born 1812) chief work, the large *History of the World*, belongs to this period, and its pure style has had a beneficial influence upon modern Icelandic prose.

Of the younger historians we may mention Þorkell Bjarnason (*History of the Reformation in Iceland*). Jón Þorkelsson (born 1822), inspector of the archives of Iceland, has rendered great services to the study of Icelandic history and literature by his editions of the *Diplomatarium Islandicum* and *Obituarium Islandicum*, and by his *Icelandic Poetry in the 15th and 16th Century*, written in Danish, an indispensable work for any student of that period. A leading position among Icelandic lexicographers is occupied by Jón Þorkelsson, formerly head of the Latin school at Reykjavik, whose *Supplement til islandske Ordbøger*, an Icelandic-Danish vocabulary (three separate collections), has hardly been equalled in learning and accuracy. Other distinguished philologists are his successor as head of the Latin school, Björn Magnússon Olsen (*Researches on Sturlunga, Ari the Wise, The Runes in the Old Icelandic Literature*—the last two works in Danish); Finnur Jónsson, professor at the University of Copenhagen (*History of the Old Norwegian and Icelandic Literature*, in Danish, and excellent editions of many old Icelandic classical works); and Valtýr Guðmundsson, lecturer at the University of Copenhagen (several works on the old architecture of Scandinavia) and editor of the influential Icelandic literary and political review, *Eimreiðin* ("The Locomotive").

The English reader can be referred to no authorities on recent Icelandic literature in his own language, but he will find interesting information in the following German works:—J. C. Poestion. *Isländische Dichter der Neuzeit.* Leipzig, 1897.—C. Küchler. *Geschichte der isländischen Dichtung der Neuzeit.* Leipzig, 1896. —Ph. Schweitzer. *Island; Land und Leute.* Leipzig, 1885.— Alexander Baumgartner. *Island und die Faroer.* Freiburg-im-Breisgau, 1889. (S. Bl.)

Ichang, a treaty port in the province of Hupeh, China, on the left bank of the Yangtse, of which it is the present upper limit of steam navigation. It is distant 400 miles from Hankow, and consequently about 1000 miles from Shanghai. All cargo to or from Szechuen is here transhipped from steamer to junk, or *vice versâ*. About 10 miles above Ichang the famed scenery of the Yangtse gorges begins. Through these the great river runs in a series of rapids, which make navigation by vessels of any size extremely difficult and even dangerous. A very large trade, nevertheless, is carried on by this route between Chungking and Ichang. As a local centre of distribution this port is of no great consequence, the transhipment trade with Szechuen being almost its sole business. The population is estimated at 35,000. The number of foreign residents is very small, trade being carried on by Chinese agents. The total trade of the port amounted in 1899 to £4,675,000, and in 1900 to £3,741,500, as compared with £1,025,800 in 1891, the principal import being cotton yarn and the principal export opium.

ICHTHYOLOGY.

The activity that prevailed in the field of ichthyology during the last two decades of the 19th century has not been surpassed in any of the other branches of zoology. In those contributions which were of a systematic or descriptive character so many additions have been made to the list of generic and specific forms that the number of known species of living fishes, which in the year 1870 was stated to have been about 8525, has since then been nearly doubled. Our acquaintance with the fish-faunas of all the geographical regions has made proportionate progress, especially in the case of North America and tropical Africa, while the use of the deep-sea trawl, with its many improvements, as well as of other instruments of capture, partly in previously unexplored oceans, has brought to light an astonishing number of new forms of oceanic fishes. There is scarcely any part of the organization of fishes which has not been made the subject of investigation by the morphologist with the view of clearing up the genetic relations of the various types. Researches into the development of the ova, and of the larval and post-larval stages, particularly of economic and oceanic fishes, have been stimulated by their important bearing upon the interests of the fishing industries. Finally, palæontological inquiries, undertaken with due reference to living forms, have resulted in important discoveries, filling up gaps in the imperfect geological record, and leading towards a better understanding of the line of evolution of certain types. In this supplementary article only some of the most important results can be dealt with, and they will be referred to in the same sequence which was adopted for the article in the earlier volumes (xii.) of the *Ency. Brit.* (ninth edition).

The systematic arrangement under which the class of fishes was presented to the student at the end of the historical sketch in the former article, and which is chiefly based on the anatomical characters demonstrated by Johannes Müller, has met with scanty acceptance from ichthyologists. It ceased to satisfy the demands of the morphologist when it was found that the heart of *Albula* and the intestine of *Chirocentrus* showed conditions capable of being interpreted as transitional characters connecting Ganoids with Teleosteans. To the palæontologist a wide separation of these two types was still less acceptable, since it was made dependent on soft structures not capable of fossilization, and therefore not available in the study of fossils. Moreover, palæontology claims to be able to demonstrate from fossil remains a continuity of the series from Ganoid to Teleostean, or, in other words, a direct genetic relationship of these types. Thus the view taken by Owen in 1866, and yet more distinctly expressed by Lütken in 1868, has been resuscitated in the most recent classification, even with the term proposed by the former for the assemblage of Ganoids and Teleosteans, viz., *Teleostomi*.

Arrangement.

The separation of *Branchiostoma* into a class distinct from that of *Pisces*—*Acrania*—which has been proposed by Haeckel, is a view now generally adopted. Cope has gone a step farther, and similarly separated the *Cyclostomi* and the extinct Ostracoderms in a class of vertebrates which he has named *Agnatha*, and which would be characterized by the want of paired fins and the supposed total absence of a lower jaw. In the class of fishes proper four types are distinguished by the presence or absence of a suspensorium, and by the development of cranial dermal ossifications and of an osseous gill-cover. Weighty objections against the class *Agnatha* have been raised by several

ichthyologists, especially by R. H. Traquair, but the Copean arrangement has been adopted in the main by Smith Woodward. These palæichthyologists are also agreed as to the Chondropterygian affinities of the *Acanthodii*, which formerly had been provisionally placed among the Ganoids, or were regarded as an annectent type between Ganoids and Chondropterygians. As far as the main divisions of extinct and living *Cyclostomi* and *Palæichthyes* are concerned, the systematic arrangement, modified by Traquair's recent researches into the Ostracoderms, appears as follows :—

Class : **Agnatha.**
- I. Subclass : CYCLOSTOMI.
  With three Orders : (*a*) *Hyperoartia* (Lampreys) ; (*b*) *Hyperotreti* (Myxinoids) ; (*c*) *Cycliæ* (Palæospondylus).
- II. Subclass : OSTRACODERMI.
  With four Orders : (*a*) *Heterostraci* (Cœlolepidæ, Psammosteidæ, Drepanaspidæ, Pteraspidæ) ; (*b*) *Osteostraci* (Cephalaspidæ, Ateleaspidæ, &c.) ; (*c*) *Antiarchi* (Asterolepidæ, Pterichthys, Bothrolepis, &c.) ; (*d*) *Anaspida* (Birkeniidæ).

Class : **Pisces.**
- I. Subclass : ELASMOBRANCHII.
  With four Orders : (*a*) *Pleuropterygii* (Cladoselache) ; (*b*) *Ichthyotomi* (Pleuracanthidæ) ; (*c*) *Acanthodii* (Diplacanthidæ and Acanthodidæ) ; (*d*) *Selachii* (divided from the structure of the vertebral centres into Asterospondyli and Tectospondyli).
- II. Subclass : HOLOCEPHALI.
  With one Order : *Chimæroidei.*
- III. Subclass : DIPNOI.
  With two Orders : (*a*) *Sirenoidei* (Lepidosiren, Ceratodus, Uronemidæ, Ctenodontidæ) ; (*b*) *Arthrodira* (Homosteus, Coccosteus, Dinichthys).
- IV. Subclass : TELEOSTOMI.
  - *A.* Order : *Crossopterygii.*
    With four Suborders : (1) *Haplistia* (Tarassius) ; (2) *Rhipidistia* (Holoptychiidæ, Rhizodontidæ, Osteolepidæ) ; (3) *Actinistia* (Cœlacanthidæ) ; (4) *Cladistia* (Polypterus).
  - *B.* Order : *Actinopterygii.*
    With about twenty Suborders : (1) *Chondrostei* (Palæoniscidæ, Platysomidæ, Chondrosteidæ, Sturgeons) ; (2) *Protospondyli* (Semionotidæ, Macrosemiidæ, Pycnodontidæ, Eugnathidæ, Amiidæ, Pachycormidæ) ; (3) *Aetheospondyli* (Aspidorhynchidæ, Lepidosteidæ) ; (4) *Isospondyli* (Pholidophoridæ, Osteoglossidæ, Clupeidæ, Leptolepidæ, &c.) ; (5) *Plectospondyli* (Cyprinidæ, Characinidæ) ; (6) *Nematognathi* ; (7) *Apodes ;* and the other Teleosteans.

Morphological and Anatomical Work.

Of the contributions to our knowledge of the morphology of fishes, none perhaps claim a higher interest than those dealing with the origin and evolution of the paired fins. Guided by the hypothetical analogy to the origin of the median fins, some morphologists (Thacker, Mivart, Dohrn, Wiedersheim) maintained that the paired fins were similarly evolved out of a lateral skin-fold, a theory which, from a palæontological point of view, has found strong support in the discovery of the structure of the paired fins of *Cladoselache* (B. Dean and S. Woodward) from the Upper Devonian, the most primitive type of shark as yet known. Also the paired series of abdominal spines of the Acanthodian, *Climatius*, is referred to as strongly suggesting an originally continuous fin-fold. The lateral fold is supposed to have been the continuation of the embryonic median fold, which on reaching the vent split into a right and left branch, and was supported by short parallel cartilaginous rods extending outwards from the body-wall. In the post-branchial and pelvic regions the fold with its cartilages broadened into fin-like flaps, while the intermediate portion disappeared. Such, indeed, is the condition of the fins in *Cladoselache*, in which these organs would not have served in locomotion, but had merely the function of "balancers" (*Ptychopterygium*) (Dean). In the

Fins.

further course of evolution, the archipterygial stage is reached by the fusion and shortening of the endoskeletal parts, the area of the fin being increased by the development of dermal rays, while, finally, the endoskeletal elements become correlated with the dermal rays, instead of with the axial skeleton. This view of the origin of the paired fins has been criticized by Semon and Gegenbaur, and certainly it has not been supported by the former's researches into the development of the fins in embryonal *Ceratodus*. According to Gegenbaur, the archipterygium is the most primitive form of fin. "An archipterygium has been the starting-point for the Crossopterygian fin as well as that of Selachians and Dipnoans; and each of these three divisions shows a modification of its own of a primitive condition which is now no more in existence, and of which palæontological evidence has hitherto not been forthcoming." According to Gegenbaur, the paired fins took their origin from the fusion of the cartilages of the posterior gill-bars, but he admits this to be merely a hypothesis (*Morphol. Jahrbuch*, xxii., 1895, pp. 119–160).

Dipnoi.—Owing to the supposed great rarity of *Lepidosiren paradoxa*, no advance was made in our knowledge of its morphology for some time after its first discovery. Many specimens, however, have more recently been obtained from Paraguay and the basin of the river Amazon, by which we have become acquainted with many new facts of its organization. J. Graham Kerr has studied the development of the ova and

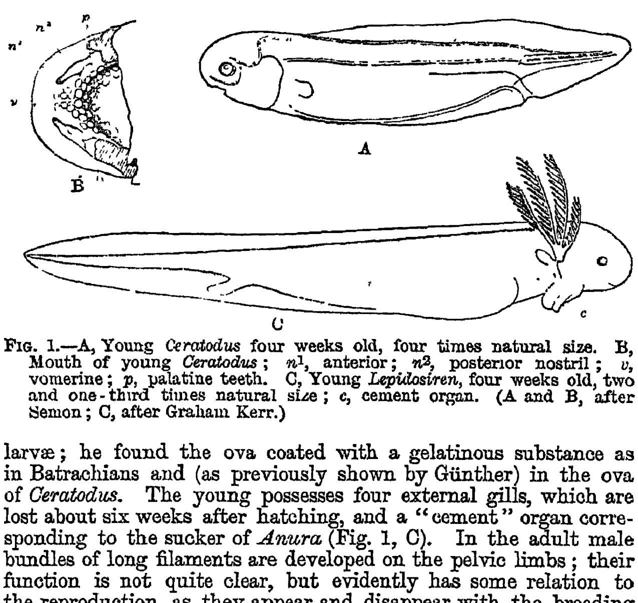

FIG. 1.—A, Young *Ceratodus* four weeks old, four times natural size. B, Mouth of young *Ceratodus* ; n^1, anterior ; n^2, posterior nostril ; *v*, vomerine ; *p*, palatine teeth. C, Young *Lepidosiren*, four weeks old, two and one-third times natural size ; *c*, cement organ. (A and B, after Semon ; C, after Graham Kerr.)

larvæ ; he found the ova coated with a gelatinous substance as in Batrachians and (as previously shown by Günther) in the ova of *Ceratodus*. The young possesses four external gills, which are lost about six weeks after hatching, and a "cement" organ corresponding to the sucker of *Anura* (Fig. 1, C). In the adult male bundles of long filaments are developed on the pelvic limbs ; their function is not quite clear, but evidently has some relation to the reproduction, as they appear and disappear with the breeding season. The morphology of the skull, and its comparison with that of other *Dipnoi*, is the subject of an elaborate paper by T. W. Bridge. *Ceratodus* also has received due attention on the part of morphology. W. Baldwin Spencer has examined in detail the arterial and venous system, pointing out its agreement in some respects with the Piscine, in others with the Batrachian type. R. Semon has collected valuable materials, and completed his researches into the external portion of the development, and into the development of the paired fins. The young of *Ceratodus* do not possess either external gills or a cement organ. In a larva four weeks old the pectoral limb projects as a short button-like flap, and the pelvic limb makes its first appearance fully a fortnight later. At that age the vomerine and palatine teeth commence to show as rounded tubercles, the latter about six in number on each side, quite distinct from one another, but corresponding to the prongs of the fully-developed tooth (Fig. 1, A, B).

Amia.—The morphology of *Amia*, particularly with regard to its cranial osteology, has been made the subject of detailed investigation by T. W. Bridge (1877), J. van Wijhe (1882), M. Sagemehl (1883), R. W. Shufeldt (1885), L. Schmidt (1892), and E. P. Allis (1897–1898). Sagemehl views the skull of *Amia* as a direct advance of conditions which already obtain in the Selachian skull, more especially in that of the *Notidanidæ*, the least differentiated type of sharks. Speaking of the skeleton generally, Shufeldt maintains that although it possesses many of the characters in common with Teleosteans, it is, on the other hand, still stamped with characters,

more particularly in its vertebral column, of a veritable palæoichthyic type.

Ostariophysi.—The peculiar communication between the auditory organ and the air-bladder, which from its discoverer has been named "Weber's Apparatus," is considered by Sagemehl (*Morphol. Jahrb.*, 1884) to indicate a genetic relationship of the four families which possess it (*Siluridæ, Cyprinidæ, Characinidæ, Gymnotidæ*). They constitute a separate division among Teleosteans, for which he proposes the name *Ostariophysi.* He also points out the many resemblances of the *Erythrinina* to *Amia*, from which he draws the inference that the ancestor of the Characines could not have been very remote from that Ganoid.

Brain.

The results of the morphological researches into the structure of the brain may be summarized thus:—The brain of fishes is characterized (1) by its relatively small size; (2) by the thinness of the walls of the neural tube, with tumour-like swellings of certain parts, and, accordingly, by the great width of the ventricles; (3) by greatly developed *Lobi inferiores;* and (4) by extensive areas of the neural tube retaining their epithelial condition, for instance, the median zone of the cerebellum. Lampreys possess a brain of the lowest type: the *bulbi olfactorii* are sessile, and pass directly into the prosencephalon, no *lobi optici* or cerebellum have been differentiated, and the roof of the brain has retained its purely epithelial character. This low condition is approached by the lowest forms of sharks and the sturgeons, although it shows in these fishes an advance by the differentiation of a cerebellum without folds. In the higher forms of sharks the ventricles are much reduced and the cerebellum shows an asymmetrical and much complicated structure. The differences which are to be observed in the various types are due to the varying position of the eyes and nostrils (*Chimæra, Cestracion, Raja*) or to the general configuration of the head (*Zygæna, Myliobatis*). Brains like that of *Isistius* represent by the form of their prosencephalon a transition to the cerebrum of *Acipenser*, *i.e.*, that of Teleosteans (Burckhardt). Whilst the brain of the *Holocephali* is only a Selachian brain slightly modified, that of *Dipnoi* approaches closely the brain of *Polypterus.* The brain of the *Ganoidei ossei* shows different grades of development, and Goronowitsch has demonstrated that they gradually lead to the Teleostean brain. In the latter only a few characters can be recognized as common to all the members of the subclass: the centres of the prosencephalon are greatly reduced and covered by a purely epithelial layer (Rabl-Rückhard); the optic lobes, on the other hand, are highly differentiated, and the cerebellum, although unpaired externally, is paired in internal structure and in development (Schäfer). Folds of the cerebellum lead to the formation of a portion of the so-called *valvula cerebelli*, which is homologous to a portion of the Selachian cerebellum. The *Scombridæ, Siluridæ, Gymnotidæ*, and *Mormyridæ* are families in which the brain shows a particularly high grade of development. In *Pleuronectidæ* the brain takes no part in the asymmetry of the head.

Lateral line system.

The lateral line system has been examined by many morphologists, from its most primitive condition in certain Selachians to its most highly specialized forms in bathybial Teleosteans, viz., by Solger (1880), G. Fritsch (1886), and Garman (1888) in Plagiostomes and Chimæra; by Allis (1889) and Collinge (1894) in Ganoids; by Sède de Licoux (1884) and Guitel (1891) in Teleosteans; and finally by Garman (1899) in deep-sea fishes. The last-named author comes to the conclusion that although in its inception the lateral canal system was tactile in function, and continues to be so in its primitive forms, the additional and very complex apparatus present in many bathybial fishes has assumed other functions; in them it acts as an illuminating and electrical organ, as an organ by means of which "the species or the sex of the individual is recognized, the members of the school are kept together, the prey is captured, and the enemy avoided," probably acting also as an organ of taste.

Morphologists seem now to be agreed as to the physiological function of the so-called *phosphorescent* or *luminous* organs. They prove to be more generally distributed among oceanic fishes than was previously known. Johann and Burckhardt have demonstrated their presence in a number of sharks, all of which, however, belong to the family *Spinacidæ.* These organs are extensively distributed over the lower half of the body, similar in structure in all the various species, and exhibit a primitive type of development. Singularly, they are found in the pelagic genera of *Spinacidæ*, and seem to be absent in the bathybial (*Centrophorus*).

Trophonematous gestation.

In some viviparous Chondropterygians (*Spinax niger, Scymnus lichia, Centrina, Acanthias vulgaris, Torpedo oculata, Trygon pastinaca, Myliobatis aquila*) the mucous membrane of the uterine dilatation of the oviduct has been observed to be beset with glandular villi, which in some cases were supposed to bear a relation to the nutrition of the embryo. However, views on this matter were very vague until Wood-Mason and Alcock obtained in India fresh specimens in sufficient number to follow up the whole course of gestation. Their observations were made on species of *Pteroplatea, Trygon*, and *Myliobatis.* In these genera the embryo (or embryos) is destitute of any enveloping membrane, and is free in the uterus. At the earlier stage of development the embryo is attached to a large yolk-sac over which a cloud of delicate branchial filaments is spread, issuing from the gill-slits (not the spiracles). These filaments assist in absorbing the nutritive yolk. As this source of nutrition is consumed the yolk-sac and the branchial filaments disappear, but in their place there arise from the whole surface of the mucosa of the uterus those glandular villi which are now destined to supply a new nutriment to the embryo, and which have been named *trophonemata* (Fig. 2). Only those situated opposite to the spiracles of the embryo attain to full functional development, growing in a bunch into these openings. They secrete a milky fluid which reaches the pharynx through the spiracles. During this stage the stomach is not differentiated structurally or functionally; the milk passes through it, and is assimilated in the spiral gut.

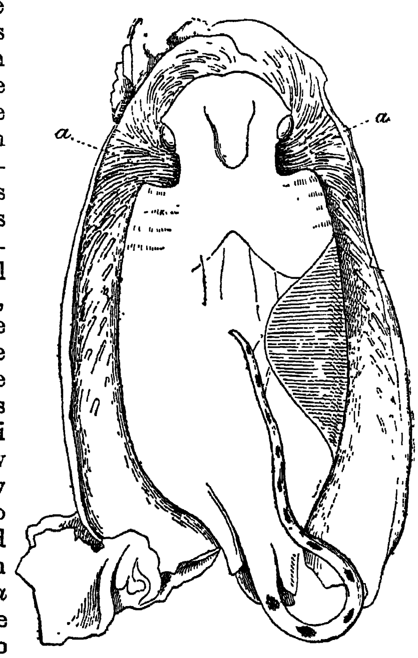

FIG. 2.—Gravid uterus of *Pteroplatea micrura*; *a*, bundles of trophonemata. (After Alcock.)

Reproduction of Cyclostomes. — The difference which obtains between *Hyperoartia* and *Hyperotreti* as regards their generative products has been known for a long time, but it has only recently been shown to extend also to the mode of their reproduction. Both *Myxine* and *Bdellostoma* are hermaphrodites, and, according to Nansen and J. T. Cunningham, the ova and sperm of *Myxine* ripen at different periods of life, each individual being a male first, and being transformed into a female at a more advanced age (protandric condition). The fertilization is not known.

Leptocephali.—The larval forms which are known under the name of *Leptocephalus* have been the subject of investigation by several Italian naturalists (Bellotti, Calandruccio, Facciola, Grassi); they generally confirm Gill's statement that the *Leptocephali* proper represent normal stages of development of *Murænidæ.* Those investigators claim to have demonstrated the Leptocephalid stage of nearly all the Mediterranean Murænoids, besides the Common Eel, the larva of which had been described as *Leptocephalus brevirostris.* It seems that the fishes of some of the other oceanic families of Teleosteans go through a similar Leptocephalid stage with the same embryonic characters. (See EEL.)

Faunistic Work.

Of the contributions by which our knowledge of the fish-fauna of certain regions has been advanced, the following may be specially referred to:—

Wallace's line.

In the Equatorial Zone two sections have been distinguished, one of the chief characteristics being the presence or absence of Cyprinoid fishes. The two sections are termed accordingly Cyprinoid and Acyprinoid divisions, the former including the African and Indian, the latter the Pacific and tropical American regions. As for other classes of animals, so for fresh-water fishes, the so-called Wallace's line was regarded as a sharp line

of demarcation between the two divisions, or more especially between the Indian and tropical Pacific faunas. Max Weber has now shown that, although the Cyprinoids offer a sufficiently distinctive character for those two faunas, Wallace's line has no significance in determining the boundary between them. The islands west of it owe the great variety of their truly Indian fish-fauna to their large size and to their longer connexion with the Indian continent, whence they also derived their Cyprinoids. On the other hand, the islands east of the line were separated at an earlier geological period, before Cyprinoids could reach them, and on account of their small size did not offer hydrographic conditions similarly favourable for the differentiation of a variety of forms. Celebes, the largest of these eastern islands, which at present would seem to be well adapted for the production of a rich fish-fauna, was formerly divided into several smaller islands, with short and insignificant rivers. Its fish-fauna is still very poor, but such as it is, and as Weber's collections have shown it to be, it bears the character of an impoverished Indian fauna, and therefore it cannot be referred to the Australian region.

African region.

With the opening up to civilization of the interior of tropical Africa many additions have been made to our knowledge of its fresh-water fishes; the list of described species has been nearly trebled. Differentiation, as far as specific, and even generic, characters are concerned, obtains in a high degree, and does not depend merely on locality. A surprising number of allied but clearly distinct species of the same genus may occur in the same river or lake, under identical physical conditions, as is shown in Boulenger's recent contributions on the fauna of Lake Tanganyika and the river Congo. This great variety is apparent especially in the families of *Mastacembelidæ*, *Chromides*, *Siluridæ*, and *Mormyri*, and reminds us of a similar abundance of fish life in the fresh waters of tropical America. However, numerous as these accessions to the fauna are, they have given no reason for modifying our views as to its general character, with one remarkable exception, viz., the occurrence in the extreme south of the continent of a species of the characteristically Antarctic genus *Galaxias*. The discovery even of a single representative of a genus limited to the Tasmanian, New Zealand, and Patagonian subregions is most significant, although it cannot affect our view that in all other respects the fish-fauna of South Africa is an impoverished branch of the African fauna generally.

Deep-sea fauna.

The deep-sea explorations which were undertaken subsequently to the *Challenger* expedition have largely extended our knowledge of the oceanic fish-fauna. Their results have been published in the magnificent works mentioned in the bibliographical notes. More than 600 true bathybial fishes are now known from depths of 1000 fathoms and more. Garman's list includes the names of about 1050 species of fishes that have been found below the 100-fathoms line, but this number seems to be excessive, since this author considers that individuals apparently identical, but captured at widely distant localities, should be specifically separated, although this "could hardly be done by the characters ordinarily used in specific diagnoses." Of the new forms many show points of special interest, but all are more or less nearly related to previously known types. A great deal of evidence (if such was needed) has been accumulated to show the gradual transition of the surface fauna into the bathybial. A much larger number of surface fishes than were known before have been met with in deep water (from 100 to 500 fathoms), *Pleuronectidæ* peculiar to deep water have been discovered, and in the Arctic regions certain bathybial types seem frequently to appear close to the surface. This intermingling of surface with bathybial fishes obtains chiefly on the slopes in the neighbourhood of land. As to the truly oceanic areas, Alexander Agassiz's experience is distinctly against the supposed existence of a "mid-water" fauna; he considers the zones intermediate between the 200-fathoms line and the bottom to be azoic. With regard to fishes, however, there is no reason why certain forms should not permanently inhabit intermediate zones, as pelagic fishes are free swimmers for nearly the whole of their life without being tied to the proximity of *terra firma*. The results of more recent explorations are not confirmatory of Agassiz's view.

The surmise that the depths of the ocean have been gradually peopled from the surface is supported by palæontology, and it is evident that this process continues to the present time. The Chalk and other Upper Cretaceous formations have yielded a number of deep-sea Teleosteans, such as *Berycidæ*, *Scopelidæ*, *Bathythrissidæ*, *Clupeidæ*, *Halosauridæ*. At the period when Physostomous fishes predominated we find that families of that type composed the fossil bathybial fauna; a few Anacanths were added to it when this type appeared in the early Tertiary period, and the highly modified eels were a still later immigration. In connexion with these notes on the bathybial fish-fauna, it should be mentioned that Alcock has found among the collections of the *Investigator* a Brotuline Ophidiid (*Saccogaster*), which is evidently viviparous, and naturally we may suppose that this peculiar form of propagation obtains also in other bathybial members of this group.

Systematic Work

Cyclostomi.—Among the multitude of new forms discovered in recent years the most remarkable is a small fossil from the Lower Old Red Sandstone of Scotland, which has been recognized by R. H. Traquair as the sole representative that has been preserved from geological times of the subclass *Cyclostomata*, and described by him under the name of *Palæospondylus gunni* (Fig. 3). It differs from all the other Cyclostomes by the calcification of its skeleton. The body is spindle-shaped, naked; the vertebral column formed by numerous ossified rings; abdominal portion with short neurals, caudal with long neurals and hæmals; brain-case complete, with a pair of trabeculo-palatine enlargements, and posterior (parachordal) auditory capsules of enormous size, terminating in front in a ring of calcified cirri which surround a large single nasal opening. The list of living Cyclostomes has also been enriched by the discovery on the coast of Chile of a remarkable form which differs from all the other known Lampreys in possessing large, well-developed, functional eyes. It has been described by L. Plate, and named *Macrophthalmia*.

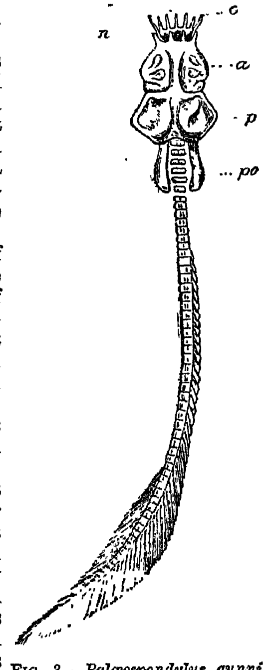

FIG. 3.—*Palæospondylus gunni.* (After Traquair.) *n*, Nasal opening surrounded by cirri (*c*); *a*, trabeculo-palatine part; *p*, parachordal part; *po*, post-occipital plates.

Ostracodermata.—In another recent contribution by R. H. Traquair our knowledge of the *Ostracodermata* is much advanced, certain genera which rested hitherto on very fragmentary evidence being made more fully known (*Thelodus*, *Drepanaspis*), while others (*Lanarkia*, *Ateleaspis*, *Birkenia*, and *Lanasius*) are new additions to this subclass. The last two prove to be types of a distinct order of Ostracoderms, *Anaspida*; they comprise small, laterally compressed fishes without paired fins, but with a single small dorsal and a heterocercal tail (Fig. 4). Both these genera are armed with a median ventral series of large spines. Their association with the Ostracoderms, however, is provisional, as they differ with regard to the structure of their dermal scutes (which are

developed in *Birkenia* at least) from the other members of this subclass. All these fossils belong to the fauna of the Scottish Silurian rocks.

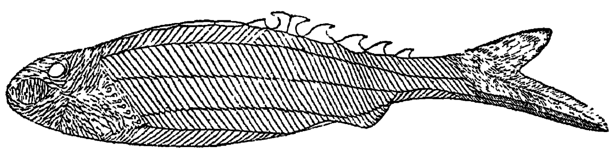

FIG. 4.—*Birkenia elegans.* (After Traquair.)

In the marl-shales of Gothland (Sweden) a form of *Cyathaspis* occurs, for which G. Lindström claims that it is not only the oldest fish, but the oldest vertebrate known; he refers that formation to the Lower Silurian.

Plagiostomata.—Among the Plagiostomes the genus *Cladoselache* (Fig. 5) from the Lower Carboniferous shales of Ohio claims special attention; it is one of the few fossil sharks whose structure is fairly well known, thanks to the labours of Dean and Smith Woodward, who consider it to be, with regard to its paired fins, the most

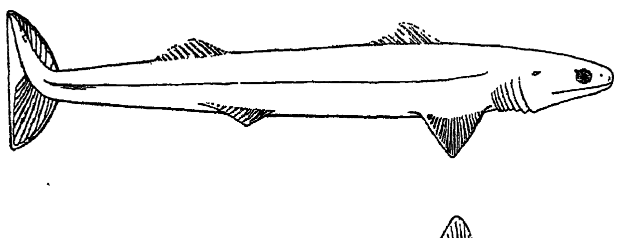

FIG. 5.—*Cladoselache fyleri.* (After Dean.)

primitive form of shark known, and the type of a separate "order," *Pleuropterygii.* The general form of the body is shark-like, but the mouth and nostrils are terminal; two dorsal fins, without spine; no claspers are developed in the ventral fins, which, like the pectorals, are believed to have had the merely initial function of "balancers"; notochord without calcification; teeth upon broad, multicuspid bases, several series functional at the same time.

The genus *Pleuracanthus* (*Xenacanthus*), although named from fragments long ago, is now known almost in its entirety, so that A. Fritsch has been enabled to represent it in a nearly complete restoration (Fig. 6). It proves to be one of the most important

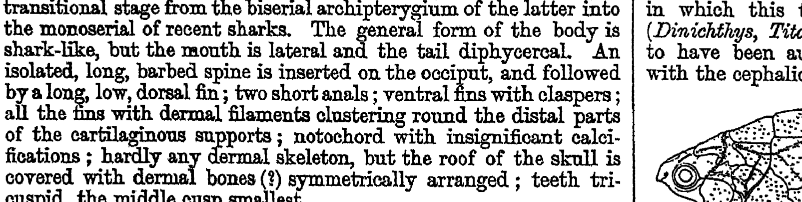

FIG. 6.—*Xenacanthus decheni.* *d*, Dorsal; *c*, caudal; a^1, a^2, anal fins. (After Fritsch.)

types connecting sharks with the Dipnoi, its pectoral fin being a transitional stage from the biserial archipterygium of the latter into the monoserial of recent sharks. The general form of the body is shark-like, but the mouth is lateral and the tail diphycercal. An isolated, long, barbed spine is inserted on the occiput, and followed by a long, low, dorsal fin; two short anals; ventral fins with claspers; all the fins with dermal filaments clustering round the distal parts of the cartilaginous supports; notochord with insignificant calcifications; hardly any dermal skeleton, but the roof of the skull is covered with dermal bones (?) symmetrically arranged; teeth tricuspid, the middle cusp smallest.

Chlamydoselache, a genus of the family of *Notidanidæ*, is the most remarkable addition to our knowledge of living sharks. It has greatly excited the attention of some naturalists, one regarding it as the oldest living type of vertebrata another making it the representative of a distinct suborder (*Selachophichthyoidei*), while to a third it has revealed the nature of the mysterious "sea-serpent." The gill-slits, six in number, are protected by broad dermal frills. The teeth are similar in both jaws, each consisting of three slender, curved cusps, separated by a pair of rudimentary denticles. According to Rose, the cusps represent separate teeth in the embryo, subsequently coalescing into a single tooth with broad bases. This shark has been associated with several extinct types, chiefly on account of its dentition. Its frilled gill-coverings remind one of a similar condition in *Cladoselache* and *Acanthodes;* but while it must be admitted to possess, like the other *Notidanidæ*, certain primitive features, it cannot be traced back farther than to teeth found in Pliocene strata of Tuscany. The history of its discovery is perhaps unique in ichthyology. Discovered first in a Japanese collection as a unique specimen in 1884, it was claimed to be a deep-sea shark in 1887—a surmise which proved to be correct when it was re-discovered off Madeira in 1889, and finally in the Varanger fjord in 1896. The habits of *Notidanus* are likewise bathybial.

A genus belonging to the family *Lamnidæ*, having the dentition of, and being generally closely allied to, *Odontaspis*, has been described from European Chalk formations and the Chalk of Mount Lebanon under the name of *Scapanorhynchus* (Fig. 7). It is distinguished

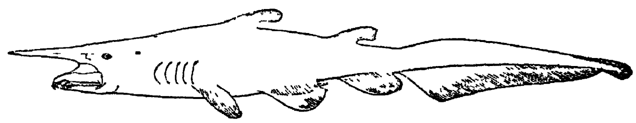

FIG. 7.—*Scapanorhynchus owstoni*, from Japan (After Jordan.)

by a peculiar prolongation of the rostrum into a long, pointed blade; it possesses distinct spiracles. This genus seems to have been a dominant type among the sharks of the Cretaceous seas, and scientific interest in it is increased by the fact that a species generically not separable from the fossil forms has recently been discovered living in Japanese seas.

Holocephali.—The small number of living Chimæras has received an addition by the discovery in the depths of the North-western Atlantic and the Japanese Sea of a form which has been described under the name of *Harriotta* (Fig. 8), and which is characterized

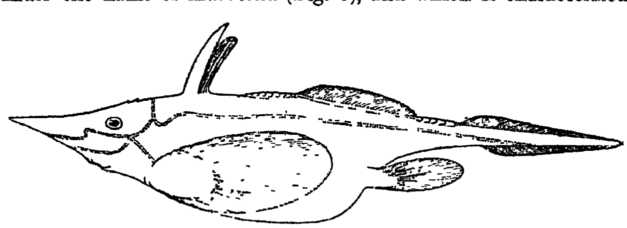

FIG. 8.—*Harriotta raleighana.* (After Goode and Bean.)

by a greatly elongated snout, the absence of a prehensile cephalic appendage, and very small rudimentary claspers. It should be remembered, however, that the two latter are secondary sexual characters, which are likewise in an undeveloped condition in the young stage of Chimæra.

Arthrodira.—The systematic position of the family *Coccosteidæ* is still rather doubtful. While Smith Woodward, with Cope, is inclined to refer them as a "suborder" to the Dipnoans, Dean considers that the existing evidence is equally in favour of their relationship to the sharks. However, much has been done towards a better knowledge of their organization. Traquair has worked out the details of the cranial, dorsal, and ventral armature of *Coccosteus* (Fig. 9) and *Homosteus* (Fig. 10) from the Old Red Sandstone of Scotland, while Newberry and Claypole have described a number of forms from passage beds between the Devonian and Carboniferous systems of North America, in which this type reached a gigantic size and development (*Dinichthys*, *Titanichthys*, *Mylostoma*, &c.). All these fishes seem to have been autostylic. The dorsal shield was so articulated with the cephalic as to admit of a considerable extent of vertical

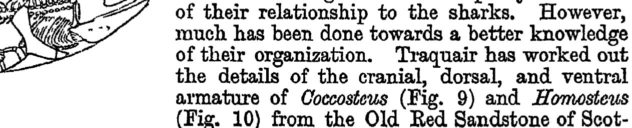

FIG. 9.—*Coccosteus decipiens.* (After Traquair.)

motion of the head (*Arthrodira*). Pectoral fins unknown, if present; tail probably diphycercal. Some of the American genera show a very distinct pineal foramen.

Chondrostei.—The structure of the Liassic genus *Chondrosteus* has been more completely made out, and its position more clearly defined. Traquair, who has paid much attention to this type,

considers that its affinities seem to radiate towards *Acipenser*, *Polyodon*, and the *Palæoniscidæ*, the distance from *Acipenser* being the least. It is confined to the Lias, while *Acipenser* and a fish allied to *Polyodon* (*Crossopholis*) have not yet been found in earlier than Eocene formations.

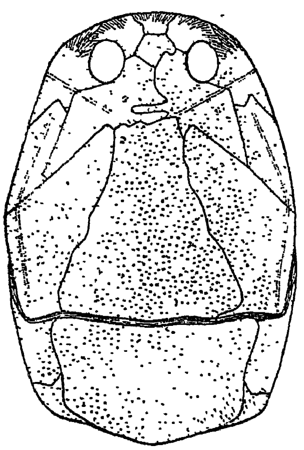

FIG. 10.—Cranial buckler of *Homosteus milleri*. (After Traquair.)

New Bathybial Fishes.—The following genera belong to the most striking additions to the fauna of the deep sea:—

Lopholatilus, a genus of *Trachinidæ*, distinguished by a large adipose flap on the nape in front of the dorsal fin, and a fleshy prolongation of the labial fold, extending beyond the angle of the mouth. Discovered in 1879, in from 70 to 130 fathoms of water, on the Atlantic coast of the United States, it attracted considerable attention by its sudden temporary disappearance, an immense number of individuals having been destroyed by climatic causes.

Rhodichthys, a genus of *Ophidiidæ*. Head thick, body or tail strongly compressed, the latter tapering, enveloped in a thin transparent, scaleless skin; vent immediately behind the humeral symphysis; snout swollen, overlapping the wide mouth; teeth in the jaws weak, none on the palate; eye of moderate size; ventrals reduced to two filaments, each bifid, and inserted on the hyoid; vertical fins continuous, but with caudal rays differentiated; gill-openings very wide; uniform bright red. Discovered by the Norwegian Expedition in the Arctic Ocean in 1280 fathoms.

Lamprogrammus, a genus of *Ophidiidæ*, distinguished by the extraordinary development of the lateral canal system. A series of luminous organs runs along the lateral line, each organ resting upon a very large scale, the whole being covered by the skin and a band of small scales much smaller than those of the body. No ventral fins. Three species are known, from depths of 400 to 700 fathoms, two being taken in the Indian Ocean by the *Investigator*, the third in the Gulf of Panama by the *Albatross*.

Sciadonus, a curious, Leptocephalus-like genus of *Ophidiidæ*. Snout very blunt; no eyes; vertical fins united at their bases, ventrals small, filaments close together, below the humeral symphysis; no cephalic spines; teeth small, in villiform bands; abdominal cavity long, with the vent far behind the head; bones of the head thin and soft. Obtained by the *Albatross* east of the Cocos Islands in 1010 fathoms.

Rondeletia, a scaleless genus of *Alepocephalidæ*. Body oblong, compressed; head very large; mouth wide; eyes of moderate size; teeth in the jaws in bands, coarsely granular; palate toothless; supra-occipital bones, with a pair of strong spines projecting forward over the orbits; dorsal and anal opposite; pectorals and ventrals small; no adipose fin; no lateral line; gills wide. Taken by the *Albatross* off the east coast of the United States in 960 to 1640 fathoms.

Cetomimus, another genus of *Alepocephalidæ*. Body moderately compressed, scaleless; mouth very wide; eyes very small; teeth in granular bands on all the bones of the mouth, tongue, and throat; dorsal and anal opposite; no adipose fin; pectorals short, ventrals none; lateral line consisting of two canals connected vertically by numerous transverse grooves; gills wide. Taken by the *Albatross* off the east coast of the United States in 1040 to 1530 fathoms.

Halimochirurgus (Fig. 11), a genus of *Sclerodermis*, distinguished

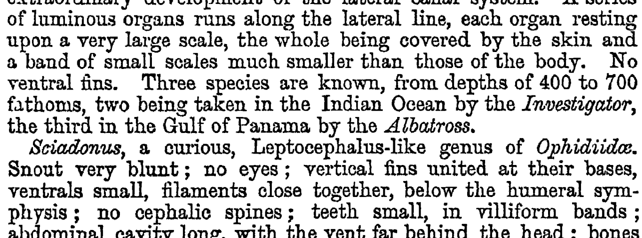

FIG. 11.—*Halimochirurgus centriscoides* (After Alcock.)

by its exceedingly long snout, which forms a curved tube with a short terminal mouth opening upwards. Tail short; a row of minute conical teeth in each jaw; eye large; two large dorsal spines, each ventral consisting of a huge spine articulating with the pelvic bone. This remarkable form is almost the only representative of the Scleroderms in the deep sea. It was captured by the *Investigator* off Cape Comorin in 143 fathoms.

AUTHORITIES.—The following selection from the extremely extensive ichthyological literature which has appeared during the period 1880–1900 will supplement the bibliographical notice in the former article. I. **The General Subject**:—B. DEAN. *Fishes, Living and Fossil.* New York, 1895.—II. **Palæontological**:—A. FRITSCH. *Fauna der Gas-Kohle und der Kalksteine der Permformation Böhmen's*, vols. i.–iii. Prague, 1879–94.—K. A. VON ZITTEL. *Handbuch der Palaeontologie*, vol. iii. Munich, 1887.—A. SMITH WOODWARD. *Catalogue of Fossil Fishes in the British Museum*, vols. i.–iii. London, 1889–95. The appearance of this work marks an epoch in ichthyological literature; when finished, it will be the most complete compendium of fossil fishes which has as yet been published. The concluding volumes will deal with the Teleosteans.—A. SMITH WOODWARD. *Outlines of Vertebrate Palæontology for Students of Zoology.* Cambridge, 1898.—E. D. COPE. IV. **Anatomical and Morphological.**—A very useful and complete list, systematically arranged, of the extremely numerous contributions which would fall under this head, has been prepared by DEAN, *Fishes, Living and Fossil*, pp. 231–251. (A. GU.)

Idaho, one of the north-western states of the American Union, lying in the northern part of the inner mountain region of the Rocky Mountains and Cascade Range. Large tracts are still unexplored, and only a small portion of the land belonging to the United States has been surveyed. The Bitter Root and Priest River forest reserves occupy parts of the state. Lying wholly or partially in the state are the Fort Hall, Duck Valley, Lemhi, Cœur d'Alene, and Fort Lapwai (school) Indian reservations. United States land offices are situated at Boise, Hailey, Blackfoot, Lewiston, and Cœur d'Alene; federal military posts are at Boise, Fort Hall, and Cœur d'Alene (Fort Sherman). The climate is diverse and changeable. The mean annual temperature at Lewiston is 56°, at Boise 51°. In the lower valleys the temperature is seldom below zero in winter, but temperature of 100° is not unusual in summer; dark or cloudy days are exceptional. The annual rainfall in southern Idaho varies from 11 to 16 inches; in the summer months it is insufficient for most crops.

Population.—The population in 1890 was 84,385 (51,290 males and 33,095 females; 66,929 native and 17,456 foreign-born; 4223 Indians). The population in 1900 was 161,772, showing an increase of 91·7 per cent. for the decade. The total land surface is approximately 84,290 square miles, and the density per square mile was 1·9 in 1900, as compared with 1·0 ten years earlier. There were thirty-three incorporated cities, towns, or villages in 1900, of which five had a population exceeding 2000. These five were Boise with 5957, Pocatello with 4046, Lewiston with 2425, Moscow with 2484, and Wallace with 2265 inhabitants. Of the total population in 1900, 93,367 (57·7 per cent.) were males and 68,405 (42·3 per cent.) females; 137,168 native-born and 24,604 (15·2 per cent.) foreign-born; 154,495 were white and 7277 (4·5 per cent.) coloured, of whom 293 were negroes, 1467 Chinese, 1291 Japanese, and 4226 Indians.

Education.—The public educational system includes the University of Idaho at Moscow (389 students and 23 teachers); two normal schools, at Lewiston and Albion; the common schools of the 750 districts (31,884 students and 793 teachers); and the graded schools of about 25 "independent" districts. The percentage of illiterates is 5·14. In 1900 the number of persons of school age (5 to 20 years) was 54,964. Out of 53,932 males of voting age 2936 were illiterate (unable to write), of whom 781 were Chinese and Japanese and 970 were Indians. A few colleges and schools are maintained by religious denominations. Schools for the education of Indians are supported and administered by the Federal Government. The state penitentiary and a soldiers' home are situated at Boise, and an asylum for the insane at Blackfoot. Of eighty newspapers and periodicals published in 1899 in Idaho, five were daily, four semi-weekly, sixty-six weekly, one semi-monthly, and four monthly.

Religion.—In 1900 it was estimated that an aggregate of 35,000 communicants included 22,000 Mormons, 8000 Catholics, 1700 Methodists, 1200 Presbyterians, and 1000 Baptists.

Mining.—Mining, stock-grazing, and agriculture are the chief industries, though manufacturing, fisheries, and lumbering have been somewhat developed. Placer mining has been prosecuted profitably in the river valleys of every county in the state, and has been succeeded by extensive quartz-mining as the parent ledges of the placer deposits have been discovered. Though gold and silver are most mined, copper, lead, and iron constitute a large part of the mineral output. Opals and sapphires are the most common of the precious stones found in various parts of the state. Deposits of coal, mica, marble, sandstone, salt, and sulphur are also worked. Of lead, 61,239 tons were produced in 1898; of copper, 36,367 pounds were produced in 1893. The gold produced in 1895 was of the value of $1,779,600, in 1898, $1,895,566; silver in 1895, $4,021,780, in 1898, $6,796,541. In 1899 Idaho yielded more than one-fifth of the total lead product of the United States, and ranked fourth among the states in the production of silver.

Agriculture.—Next to mining, the most important industry is the grazing of horses, cattle, and sheep. The grazing lands amount to not less than 25,000,000 acres. The cultivable area of about 15,000,000 acres is utilized for a variety of crops, according to altitude and humidity or aridity of climate. Wheat, oats, barley, and other grains, and turnips, potatoes, and other vegetables are supplemented with a large yield (especially in the lower valleys) of many kinds of fruits and berries. Forage crops, chiefly of timothy, clover, and alfalfa, are almost universal. In the southern part of the state agriculture is dependent on irrigation. The acreage, production, and value of the principal crops in 1900 were as follows: Wheat, 149,261 acres, yielding 3,104,629 bushels, valued at $1,428,129; oats, 36,881 acres, yielding 1,349,845 bushels, valued at $539,938; barley, 12,165 acres, yielding 399,012 bushels, valued at $199,506; potatoes, 5030 acres, yielding 684,080 bushels, valued at $321,518; hay, 235,394 acres, yielding 659,103 tons, valued at $4,284,170. In the case of the last three crops the value is the farm value 1st December. On the 1st January the number and value of farm animals were as follows: 127,821 horses, $2,863,504; 2,658,662 sheep, $7,444,254; 33,075 milch cows, $1,055,092; 364,853 other cattle, $8,672,748.

Assessment and Banks.—The assessed valuation of property for taxation in 1899 was $46,719,990. The amount of the bonded and other indebtedness in 1900 was $427,500. There are ten national banks, with an aggregate capital of $600,000, an aggregate surplus of $275,374, and aggregate deposits of $1,829,286; there are also eighteen state banks and private banks, with an aggregate capital of $366,550.

Railways.—The railways operated in the state are the Oregon Short Line (765 miles), the Northern Pacific (188 miles), the Great Northern (83 miles), the Oregon Railway and Navigation lines (87 miles), the Boise, Nampa, and Owyhee and Idaho Northern (40 miles), and the Pacific and Idaho Northern (40 miles), with a total mileage of 1203 miles.

Manufactures.—According to the U.S. census of 1900, the number of manufacturing establishments in the state (excluding 75 having an annual product of less than $500 each, and one Government establishment) was 591, with a total invested capital of $2,941,524. There were 97 salaried employees and an average number of 1477 wage-earners. The added values of the products in the different establishments amounted to $4,020,532. There were 34 establishments devoted to flouring and grist mill products, with a capital of $569,107 and annual products of $832,207; and 117 establishments devoted to lumber and timber products, with a capital of $913,352 and annual products of $937,665.

Settlement.—From 1848 to 1853 the territory comprised in the state was a part of the territory of Oregon; from 1853 to 1859 it was partly in the territory of Oregon and partly in the territory of Idaho (including part of Montana until 1864 and part of Wyoming until 1868) until 1890, when the state was organized with its present boundaries. The permanent settlement of the territory dates from the discovery of gold in 1860, though a few trading-posts and Indian missions had been established earlier. The capital of the territory of Idaho was at first at Lewiston, but was removed to Boise in 1863. Two uprisings of the Indians in the Nez Percés war of 1877 and the Shoshone war of 1878 occasioned much loss of life and property to settlers.

Administration.—The legislature consists of twenty-one senators and forty-nine representatives, serving for terms of two years, and its sessions are biennial. The governor exercises a qualified veto on legislation. The lieutenant-governor presides over the Senate, and a speaker over the House of Representatives. The governor and other executive officers are elected by popular vote for terms of two years. The Australian ballot is prescribed by law, and the suffrage in all elections may be exercised by both men and women, citizens of the United States, after six months of residence in the state. In taxation the chief reliance is placed on the general property tax, licenses, and poll taxes. State aid to persons (except paupers or other dependants) or corporations is prohibited. Corporations, whether public or private, may be created only by general laws. Impeachments are made by the House of Representatives and tried by the Senate.

Justice.—The supreme court consists of a chief justice and two associate justices, elected biennially for terms of six years. Five district courts in the state are held by judges elected for terms of four years. Probate judges and justices of the peace are elected in the counties and precincts. Idaho is in the Eighth Federal Circuit, and the entire state constitutes one Federal district. In legal precedure it is a "code" state as distinguished from "common-law" states. (See LAW: *United States.*) In a civil action three-fourths, and in a criminal action for a misdemeanour five-sixths, of a jury may render a verdict. The pardoning power is reposed in a Board of Pardons, consisting of the governor, secretary of state, and attorney-general.

Politics.—Before 1897 all the governors, senators, and representatives of the state had been Republicans, though the electoral vote had been cast for the candidate of the Populists for President in 1893. Since 1896, however, Democrats, Silver Republicans, and Populists, by the "fusion" of their parties, have been elected to the offices of governor, senator, and representative, while the electoral vote of the state has been cast in favour of a fusion candidate for President. (J. P. D.)

Idar, or EDAR, a native state of India, forming part of the Mahi Kantha agency, within the Gujarat division of Bombay. It has an area of 1900 square miles, and had a population in 1881 of 258,429 and in 1891 of 302,134. The estimated gross revenue in 1897–98 was Rs.6,28,670, of which Rs.27,065 was expended on public works; there is a tribute to the Gaekwar of Baroda of Rs.30,340. The line of railway from Ahmedabad through Parantij to Ahmednagar (55 miles) runs mainly through this state. Much of the territory is held by kinsmen of the Raja on feudal tenure. The town of Idar is 64 miles north-east of Ahmedabad. Population (1891), 7086.

Iddesleigh, Stafford Henry Northcote, 1st EARL OF (1818–1887), British statesman, was born in London, 27th October 1818. His ancestors had long been settled in Devonshire. After a successful career at Balliol College, Oxford, he became in 1843 private secretary to Mr Gladstone at the Board of Trade. He was afterwards legal secretary to the Board; and, after acting as one of the secretaries to the Great Exhibition of 1851, co-operated with Sir Charles Trevelyan in framing the report which revolutionized the conditions of appointment to the Civil Service. He entered Parliament in 1855 as Conservative M.P. for Dudley, and was elected for Stamford in 1858, a seat which he exchanged in 1866 for North Devon. Steadily supporting his party, he became President of the Board of Trade in 1866, Secretary of State for India in 1867, and Chancellor of the Exchequer in 1874. In the interval between these last two appointments he had been one of the commissioners for the settlement of the *Alabama* difficulty with the United States, and on Mr Disraeli's elevation to the House of Lords in 1876 he became leader of the Conservative party in the Commons. As a finance minister he was largely dominated by the lines of policy laid down by Mr Gladstone; but he distinguished himself by his dealings with the Debt, especially his introduction of the New Sinking Fund (1876), by which he fixed the annual charge for the Debt in such a way as to provide for a regular series of payments off the capital. His temper as leader was, however, too gentle to satisfy the more ardent spirits among his own followers, and party cabals (in which Lord Randolph Churchill—who had made a dead set at the "old gang," and especially Sir Stafford Northcote—took a leading part) led to Sir Stafford's transfer to the Lords in 1885, when Lord Salisbury became Prime Minister. Taking the title of Earl of Iddesleigh, he was included in the Cabinet as First Lord of the Treasury. In Lord Salisbury's 1886 ministry he became Secretary of State for Foreign Affairs, but the arrangement was not a comfortable one, and his resignation had just been decided upon when on 12th January 1887 he died very suddenly at Lord Salisbury's official residence in Downing Street. Lord Iddesleigh was elected Lord Rector of Edinburgh University in 1883, in which capacity he addressed the students on the subject of "Desultory Reading." He had little leisure for letters, but amongst his works were *Twenty Years of Financial Policy* (1862), a valuable study of Gladstonian finance, and *Lectures and Essays* (1887). His biography, by Mr Andrew Lang, appeared in 1890.

Idle. See BRADFORD.

Idria, a mining town in the Austrian duchy of Carniola. In 1892 there were 1116 miners employed in the quicksilver mines and 224 labourers in the smelting works. In 1898, 4913 metric centners of refined mercury were recovered, amounting in value to over £95,700. It is calculated that the state monopoly has had a clear profit of £2,000,000 from these mines in the period 1814–80. Population (1890), 4906; (1900), 5772.

Iglau (Czech, *Jihlava*), an autonomous town in Moravia, Austria. It is second only to the capital, Brünn,

in size and population, and is a German enclave. It has the principal tobacco and cigar factory of the state monopoly (which gives employment to 2500 hands), and has, besides, a large and important textile and glass industry, steam corn and saw-mills, pottery and brewing. Population, mostly Germans and Roman Catholic, but with a sprinkling of Czechs (1890), 23,700; (1900), 24,387.

Ignatief, Nicholas Pavlovitch, COUNT (1832———), Russian diplomatist, was born at St Petersburg on the 29th of January 1832, and became at the age of seventeen an officer of the Guards. His diplomatic career began at the Congress of Paris, after the Crimean war, where he took an active part as military attaché in the negotiations regarding the rectification of the Russian frontier on the Lower Danube. Two years later he was sent with a small escort on a dangerous mission to Khiva and Bokhara. The khan of Khiva laid a plan for detaining him as a hostage, but he eluded the danger, and returned safely, after concluding with the khan of Bokhara a treaty of friendship. His next diplomatic exploit was in the Far East, as plenipotentiary to the court of Peking. When the Chinese Government was terrified by the advance of the Anglo-French expedition of 1860 and the burning of the Summer Palace, he worked on their fears so dexterously that he obtained for Russia not only the left bank of the Amur, the original object of the mission, but also a large extent of territory and sea-coast south of that river. This success was supposed to prove his capacity for dealing with Orientals, and paved his way to the post of ambassador at Constantinople, which he occupied from 1864 till 1877. Here his chief aim was to liberate from Turkish domination and bring under the influence of Russia the Christian nationalities in general and the Bulgarians in particular. His restless activity in this field, mostly of a semi-official and secret character, culminated in the Russo-Turkish war of 1877–78, at the close of which he negotiated with the Turkish plenipotentiaries the treaty of San Stefano. As the war which he had done so much to bring about did not eventually secure for Russia advantages commensurate with the sacrifices involved, he fell into disfavour, and retired from active service. Shortly after the accession of Alexander III. in 1881, he was appointed minister of the interior on the understanding that he would carry out a nationalist, reactionary policy, but his shifty ways and his administrative incapacity so displeased his imperial master that he was dismissed in the following year. After that time he exercised no important influence in public affairs.

Ignatius, Epistles of.—If the Epistles ascribed to Ignatius of Antioch are genuine, they are of the greatest importance both for their Christology and for their evidence as to the early growth of ecclesiastical organization; and the subject has risen to such importance in recent years, and has been so carefully studied, that it calls for fresh treatment. The subject is complicated by the fact that the so-called Acts of his Martyrdom, formerly much relied upon, are now acknowledged on all hands to be spurious, and by the fact that the letters have come down to us in three different forms: (1) The *shorter Greek recension* (known as G¹), consisting of letters to the Ephesians, Magnesians, Trallians, Romans, Philadelphians, Smyrneans, and to Polycarp; it is known to us in one codex only, the Medicean MS. at Florence, from which it was published by Vossius in 1664. There is also a very exact Latin version (made in England, by Robert Grosseteste or one of his scholars, and published by Usher in 1644), fragments of a Syriac translation, a complete Armenian version from the Syriac, and fragments of a Sahidic version first published by Lightfoot. The *Epistle to the Romans* is found also (apart from the other epistles) with the *Martyrdom*, both in Greek and Syriac. (2) The *longer Greek recension* (G^2), consisting of the seven letters above mentioned with additions, and also letters from Mary to Ignatius, Ignatius to Mary, to the Tarsians, Philippians, Antiochenes, and to Hero. This exists in several MSS. and in a Latin version (to some copies of which are appended three additional letters known only in Latin, and apparently composed in that language: to St John, to the Blessed Virgin, and from the Blessed Virgin to Ignatius); whilst the Armenian version mentioned above contains also renderings of the additional letters of this recension. G^2 was published in 1557 by Pace, and two years later, independently, by Gessner. (3) The *shorter Syriac recension* (S), containing three letters (to the Ephesians, Romans, and to Polycarp) in a form much shorter than that of G^1. It was published in 1846 by Cureton from two MSS. brought from the Nitrian desert. Another MS. was found in 1847 and used by Cureton for his *Corpus Ignatianum* (1849), and additional fragments have been published subsequently by Lands and Mösinger.

Which, then, of these three forms, if any, is genuine? The criticism falls into three main periods: (*a*) Down to the finding of G^1. During this period the three letters only extant in Latin were given up, but otherwise opinion was divided. Baronius and other Roman Catholics accepted G^2, subject to possible interpolations, whilst the Magdeburg Centurators and others recognized only the first seven (as being mentioned by Eusebius, *H. E.* iii. 36), and held that these were interpolated. (*b*) Since the publication of G^1, few attempts have been made to defend G^2; the additional matter has by degrees been entirely discarded, and it has been shown by Zahn and Lightfoot that G^2 was composed after the middle of the 4th century, in all probability by the redactor of the APOSTOLICAL CONSTITUTIONS (*q.v.*). Opinions differed as to G^1: Pearson defended it against Daillé and Salmasius in the 17th century, whilst in the 19th Baur held that it was forged after A.D. 150 to uphold the "theory of the Catholic Church" as then recently invented. (*c*) The publication of S reopened the whole question. Cureton unhesitatingly accepted it and rejected G^1; so did Bunsen, and many other English and German scholars, including Ritschl and Lipsius; on the other hand, Baur held that S was derived from G^1 and not *vice versa*, whilst Hefele, Denzinger, Uhlhorn, Jacobson, and others declared for the genuineness of G^1. Little by little S was rejected, mainly because its contents lacked anything like internal unity. Lipsius and Lightfoot, amongst others, gave it up in favour of G^1; and the question, so far as it concerns S, may now be said to be closed. Meanwhile, fresh critical examination has resulted strongly in favour of G^1. The opinion of Renan and others, that the *Epistle to the Romans* is of different origin from the other epistles, has been disproved by Harnack. Zahn, Funk, and other German scholars have vindicated the genuineness of the whole seven. Above all, the case has been exhaustively studied by Bishop Lightfoot. His careful comparison of the Greek of the portions of G^1 which exist also in S with that of those which do not, shows conclusively that they are one in origin; whilst a similar comparison in the case of G^1 and G^2 leads to the opposite conclusion. There is no longer any doubt, then, that, of the forms which we possess, G^1 is the original, and that it shows no sign of compilation, the style of the letters being the same throughout. Further, after a study of the whole question which for minuteness and accuracy is unequalled, he unhesitatingly decides that the seven letters are the genuine epistles of Ignatius. In England at the present time the matter is generally regarded

as settled; in Germany, too, these conclusions are very widely though not universally accepted, and Harnack, who formerly dated the epistles about 140, now agrees that a date in the lifetime of Trajan is possible. Objections are indeed raised against this date, and against the genuineness of the letters, on the ground that they show signs of having been written with a definite theological motive; that they deal with heresies of a date later than that of Ignatius; that the ecclesiastical order disclosed in them is also of a later date, and that the same thing is true of the title καθολικὴ ἐκκλησία (*ad Smyrn.* viii.). But such objections are not hard to answer. It is doubtless true, although the fact used to be denied, that Ignatius writes with the definite aim of exalting the episcopal office as the guarantee of the unity of the Church, but nevertheless it occupies in his letters a much less developed position than, *e.g.*, in the writings of Irenæus. The heresies referred to in the letters have at least as much analogy with those of earlier date as with those of later. And although Ignatius uses the title καθολικὴ ἐκκλησία, he does so from a point of view different from that which is involved in the later use of the title.

On the whole it is safe to say, with Uhlhorn, that the objections to the genuineness of the letters from internal evidence are so flimsy that they cannot stand against any real external evidence; and this is supplied by the abundant use of the letters which is made by Polycarp in his *Epistle to the Philippians*, witnessed to in turn by Irenæus. Until it is proved that Polycarp's epistle is interpolated throughout, the genuineness of the seven letters cannot reasonably be impeached again.

The known facts with regard to Ignatius rest almost entirely upon the Letters, for, as we have said, the Acts of his Martyrdom are spurious. He was bishop of Antioch; he was condemned to death, and conveyed from Antioch to Rome by a guard of soldiers, to be put to death by beasts in the amphitheatre. The letters to the Ephesians, Magnesians, Trallians, and Romans were sent from Smyrna, where Ignatius was able to be in communication with Polycarp, the bishop of Smyrna. Thence he passed on to Alexandria Troas, where the other three letters were written. Thence, it is to be presumed, he crossed to Europe, and suffered martyrdom in Rome; but of this we have no evidence of early date.

Igualada, a town of Spain, in the province of Barcelona. The local industries have developed since 1880, especially the manufactures of cotton, linen, wool, ribbons, cloth, chocolate, soap, brandies, leather, cards, and nails. The surrounding districts, though hilly, are well cultivated, and send many products of agriculture to the fairs in the town. There is a narrow-gauge railway connecting Martorell, Barcelona, and Tarragona. Little has been done even for primary education. Population (1887), 10,201; (1897), 10,419.

Iki, an island belonging to Japan, lying off the north-western coast of Kiushiu, in 33° 45′ N. lat. and 129° 40′ E. long. It has a circumference of 86 miles, an area of 51 square miles, and a population of 36,530. The island is, for the most part, a tableland about 500 feet above sea-level. The anchorage is at Gonoura, on the south-west. A part of Kublai Khan's Mongols landed at Iki when about to invade Japan in the 13th century, for it lies in the direct route from Korea to Japan *viâ* Tsushima. In the immediate vicinity are several rocky islets.

Iletsk, formerly FORT ILETSKAYA ZASCHITA, a town of Russia, government and 45 miles south of Orenburg, near the Ilek river, a tributary of the Ural. A large bed of excellent rock-salt of great thickness, representing the richest rock-salt deposit known, is worked here to the extent of from 16,000 to 24,000 tons annually. The place is resorted to for its salt, mud, or brine baths and koumiss cures. Population, 11,802.

Ilford, or GREAT ILFORD, a town in the Romford parliamentary division of Essex, England, on the Roding, 7 miles east-north-east of London by rail. A portion of Hainault Forest lies within the parish. There are a library and reading-room, a drill hall, and swimming baths. The Hospital of St Mary and St Thomas, founded in the 12th century as a leper hospital, now contains almshouses and a chapel, and belongs to the marquis of Salisbury, who as "Master" is required to maintain a chaplain and six aged inmates. Claybury Hall is a lunatic asylum (1893) of the London County Council. There are large photographic dry-plate works, and paper mills. Area of civil parish (an urban district), 8493 acres. Population (1881), 7645; (1901), 41,240. LITTLE ILFORD is a parish on the west side of the Roding, with an area of 768 acres. Population (1891), 3969; (1901), 17,915.

Ilfracombe, a watering-place in the Barnstaple parliamentary division of Devonshire, England, on the Bristol Channel, 225 miles west of London, on the London and South-Western Railway. The town has advanced in favour as a popular seaside resort, and the number of winter visitors has also steadily increased. It has been connected with the Great Western Railway system by coach from Minehead, and in the summer the Midland Railway run handsome steamers from Sharpness in connexion with their system. A Victoria Promenade for inclement weather was erected in 1888 on the townward base of the Capstone Rock, and a Baptist chapel in 1891, whilst the town and harbour have been generally improved. Area of parish (an urban district), 5627 acres. Population (1881), 6255; (1901), 8557.

Ilhavo, a town of Portugal, district Aveiro, 3 miles south-west of Aveiro. It has a fine parish church, and is famous for the beauty of its women. Wheat, millet, vegetables, fruits, and wine are cultivated. Nearly 2000 of the people, using 550 boats, are engaged in fishing, the annual value being about £12,200. It was founded by a colony of Pelasgic Greeks. Population (1890), 10,762; (1900), 12,545.

Ilion, a village of Herkimer county, New York, U.S.A., on the river Mohawk, the Erie canal, and the New York Central and Hudson River Railway. It has manufactures of agricultural implements, small-arms, sewing-machines, and typewriters. Population (1900), 5138, of whom 755 were foreign-born.

Ilkeston, a municipal borough (1887) and market town in the Ilkeston parliamentary division of Derbyshire, England, 9 miles east-north-east of Derby by rail. Recent structures include two Established churches, a large Wesleyan church, and a hospital. Area, 2526 acres. Population (1881), 14,122; (1891), 19,744; (1901), 25,383.

Ilkley, a town and railway station in the Otley parliamentary division of Yorkshire, England, on the Wharfe, 10 miles north by west of Bradford. The neighbourhood is famous for its romantic scenery, and the town has become a favourite health resort. All Saints' Church, restored in 1860, is mostly ancient, and contains interesting memorials; there are also another church, a Roman Catholic and other places of worship. Here and at Ben

Rhydding, 1 mile to the east, there are nearly a dozen hydropathics, all built since the middle of the 19th century. The oldest and largest of these stand high up amongst the grouse moors, and thus derive the full benefit of the bracing air. The place occupies the site of an old Roman station. Its institutions embrace a museum of local antiquities, a grammar school, the Siemens Convalescent Home, the Ilkley Bath Charitable Institution, a golf course; and 5 miles higher up the valley is Bolton Abbey. Area of civil parish (an urban district), 3822 acres. Population (1851), 811; (1881), 4736; (1901), 7455.

Ill, a river of Germany, entirely within the imperial territory of Alsace-Lorraine. It rises on a north foothill of the Jura, south-west of Basel, flows north-north-east parallel with the Rhine, which it enters from the left 11 miles below Strasburg. Its course lies for the most part through low meadowland; and the stream, which is 130 miles long, receives numerous small affluents, which pour out of the short, narrow valleys of the Vosges. It is navigable as far as Colmar, a distance of 60 miles. It is on this river, and not on the Rhine, that the principal towns of Upper Alsace are situated—*e.g.*, Mülhausen, Ensisheim, Colmar, Schlettstadt, and Strasburg. The Ill feeds two important canals, the Rhine and Marne canal and the Rhine–Rhone canal, both starting from the neighbourhood of Strasburg.

Ille-et-Vilaine, a department in the north-west of France, bordering on the English Channel.

Area, 2699 square miles. The population increased from 621,384 in 1886 to 622,039 in 1896, but decreased to 611,477 in 1901. Births in 1899, 14,893, of which 722 were illegitimate; deaths, 13,916; marriages, 4834. There were in 1896, 921 schools, with 96,000 pupils. The illiterate composed 6 per cent. of the population. Of the cultivated land in 1896, amounting to 1,472,801 acres, 1,114,485 acres are plough-land and almost all the rest grass-land. Of the cereals, wheat in 1899 yielded the value of £1,460,000; barley, £260,000; buckwheat, £490,000; oats, £378,000. Green crops amounted to the value of £190,000; natural pasture and grass lands, £860,000. The department produces a little linen, hemp, and colza; and its apples for cider yielded the value of £749,000 in 1899. The department owned in 1899, 69,340 horses, 352,890 cattle, 30,480 sheep, and 107,980 pigs. The value of milk products in 1899 was £1,880,000. The mining industry produces only a little iron, but other minerals to the value of about £112,000. The other industries are in a backward state. Rennes, the capital, had 74,006 inhabitants in 1901.

Iller, a river of Bavaria, rising in the south-west extremity of the kingdom, among the Algäuer Alps, and flowing north past Kempten and Memmingen, forming for some distance the boundary between Bavaria and Würtemberg, and eventually striking the Danube (right bank) just above Ulm. It is in character a mountain torrent, and causes frequent inundations. Its total length is 103 miles; between Kempten and Ulm it has a fall of over 2000 feet.

Illinois, a state of the United States of America, bounded on the N. by Wisconsin, on the E. by Indiana and the Wabash and Ohio rivers, on the S. by the Ohio, and on the W. by the Mississippi. It was named after its principal river, which had itself been named from a confederacy of North American Indians who once occupied the territory. The state was admitted into the Union, 3rd December 1818. Its capital is Springfield, and the existing constitution was adopted in 1870. Under the law of 1901 the state has twenty-seven votes in the electoral college. Its representation in Congress, dating from 1903, consists of two senators and twenty-five representatives. Prior to 1860 the Democratic party prevailed in Illinois in every Presidential election. Prior to 1857 the Democrats always elected the Governor. Since that time the Republicans have carried the state, except in 1890, when the Democrats elected their state ticket and obtained a majority in the General Assembly, and in 1892, when they again carried the state for their state and national tickets. In 1889 the Republicans passed an obnoxious compulsory school law, which alienated the German Lutheran vote and was in some degree responsible for these defeats. In 1900 the popular vote for Presidential electors was: Republican, 597,985; Democratic, 503,061; Prohibition, 17,626.

Administration.—The executive department consists of a governor, lieutenant-governor, secretary of state, auditor of public accounts, treasurer, superintendent of public instruction, and attorney-general. Each holds office for four years, except the treasurer, who holds for two. The governor receives a salary of $6000 per annum, and has in addition the use and occupation of the executive mansion. The law-making power is vested in a General Assembly, composed of a Senate and House of Representatives. The Senate consists of 51 members, elected for four years, and the House of 153 members, elected for two years. A senator must have attained the age of twenty-five years, and a representative twenty-one years. The legislature meets biennially in odd years; the elections are held in even years. Since 1895 members receive $1000 for regular sessions, and $5 a day for special sessions. They are allowed $50 a session for stationery, and 10 cents a mile to and from the seat of government. A two-thirds vote of each House is necessary to pass a Bill over the governor's veto. Minority representation in the House is secured by the constitution.

Justice.—The Supreme Court consists of seven judges, elected in judicial districts. They hold office for nine years. Under the law of 1897 they receive a salary of $7000 per annum. They must be thirty years of age. Since 1897 the law requires the Supreme Court to meet at Springfield only. The circuit and superior court judges hold office for six years, and the county court judges for four years. The legislature is authorized to create in districts appellate courts, from which appeals lie to the Supreme Court. Four such courts have been established. The appellate courts are held by judges of the circuit courts. The judges of the circuit and superior courts of Cook (Chicago) county receive under a law of 1901 a salary of $10,000 a year. The legislature may provide for a probate court in counties having a population of over 50,000.

Education.—The state has made a great advance in its educational institutions since 1890. It has twenty-five colleges and universities. The more important of these are the University of Chicago, in Chicago; Northwestern University, having departments in Chicago and Evanston; and the State University in Champaign. These institutions have a large attendance of students, satisfactory standards and equipment. The property of the University of Chicago amounts to $12,000,000, and that of Northwestern to $5,000,000. The State University is supported by state funds. Mention should be made, among others, of Lake Forest University at Lake Forest, Knox College at Galesburg, Illinois College at Jacksonville, Wheaton College at Wheaton, the Illinois Wesleyan University at Bloomington, and the Female College at Rockford. The Armour Institute of Technology in Chicago is one of the best endowed institutions of its kind in the United States. In 1897 George M. Pullman left $1,200,000 to establish a manual training school in the town of Pullman. The Lewis Institute in Chicago has property in excess of $1,000,000. In Chicago are flourishing schools of law, medicine, theology, dentistry, and pharmacy. The state maintains out of the public funds 4 normal schools. There are 311 high schools, in which, 30th June 1900, 38,620 students were enrolled, 14,934 males and 23,686 females. The number graduated from the high schools that year was 4708—1578 males and 3130 females. The number of high schools having a course of study of three years was 88; a course of four years, 218; and a course of five years, 5. The number of school districts in 1900 was 11,771, and the number of teachers employed 26,313—6950 men and 19,363 women. The whole number of public schools was 12,762. The number of private schools was 785, the number of teachers 3908—1342 men and 2566 women. The number of children of school age, six to twenty-one years, was 1,588,895, and of this number 958,911 were enrolled in the public schools and 142,496 in private; the total attendance being 1,101,407. The average daily attendance was 737,576. The average school year was 142·8 days. The highest monthly salary paid to male teachers in the public schools was $300, and to female teachers $280. The average monthly salary paid to male teachers was $60·42, and to female

teachers $53·27. The total amount of public money expended for the year ending 30th June 1900 was $18,167,219·32. Since 1873 there has been an annual state tax for school purposes of $1,000,000. The school district tax levy for 1899 was $15,850,804, or $16·53 per pupil enrolled. The permanent school funds, the income alone being available, amount to $17,429,569. The estimated value of the school property in 1900 was $51,403,089. This is exclusive of the property under private control. In 1899 a law was passed providing free text-books for children in public schools. The constitution prohibits the appropriation of any public fund in aid of any educational institution under sectarian control. Under the census of 1900 the percentage of males of voting age who were illiterate was 4·8.

Military.—In the war against Spain in 1898 the state rendered prompt and efficient service. The Fifth Illinois regiment was the first volunteer regiment in the United States to be mustered into the Federal service in that war. The total number of men furnished to the army was 13,647, divided as follows: infantry, 12,194; cavalry, 1275; light artillery, 178. The state had in its military service, 1st January 1901, 7122 officers and men. These were divided into eighty-six companies of infantry, eight of cavalry, two of artillery, one of engineers, and one signalling corps. The total number of officers and men in the naval militia was 631: 56 officers, 99 petty officers, and 476 enlisted men. During the war of the Rebellion the state furnished to the army of the United States 259,092 men; the quota demanded by the President was 244,496.

Prisons.—The appropriation for 1900 for the ordinary expenses of each of the two prisons was $90,000. The prison at Joliet returned unexpended to the treasury $25,000. The appropriation for the reformatory at Pontiac was $266,100. This provided for improvements and running expenses; $50,000 was returned to the treasury. The number of prisoners in confinement in the state prisons on 1st January 1901 was as follows: at Joliet, 1198 males and 61 females; at Menard, 855 males; at Pontiac, 1282 males. A law of 1895 established the parole (ticket-of-leave) system in the punishment of adult criminal offenders, except in cases of treason, murder, and rape. No prisoner is eligible to go upon parole until he has served the minimum term provided by law for the crime of which he was convicted. Each paroled prisoner must report once a month to the prison authorities, and six months of good behaviour secures final release. For 1900 there were 1662 applications for parole, and 631 were granted.

Charities.—A Board of State Commissioners of Public Charities has supervision of the charities and correctional institutions, state prisons excepted. The following are the institutions maintained: Northern Hospital for Insane, Elgin; Eastern Hospital for Insane, Kankakee; Western Hospital for Insane, Watertown; Central Hospital for Insane, Jacksonville; Southern Hospital for Insane, Anna; Asylum for Incurable Insane, Peoria; Asylum for Insane Criminals, Chester; Soldiers' and Sailors' Home, Quincy; Soldiers' Widows' Homes, Wilmington; Charitable Eye and Ear Infirmary, Chicago; State Home for Female Juvenile Offenders, Geneva; Institution for Education of Deaf and Dumb, Jacksonville; Institution for Education of the Blind, Jacksonville; Asylum for Feeble-minded Children, Lincoln; Soldiers' Orphans' Home, Normal. Under the law governing commitment and detention of lunatics 4846 insane cases were tried in the courts during the biennial period ending 30th June 1900. Of this number 2669 were males and 2177 females; 3451 were tried by jury, and 1395 by commission. The number of inmates in asylums for the insane on 30th June 1900 was 6438. For the two years beginning 1st July 1899 the General Assembly appropriated to state charitable institutions $4,350,161; for ordinary expenses $3,153,520, and for special purposes $1,196,641. The total valuation of the property belonging to the fifteen state charitable institutions as reported on 30th June 1900 was $7,400,000. In 1899 "An Act to establish the Illinois State Colony for Epileptics" was passed. The state Board of Charities estimated the number of epileptics in 1900 as 5000.

Agriculture.—Illinois occupies a leading position among agricultural states. In the value of its farms, at the census of 1890, it stood first among the states of the Union. The state lies in the centre of a great agricultural valley, and the diversity of soil and climate enables it to produce a great variety of cereals, vegetables, and fruits. Its black soil has great fertility. Since September 1895 a permanent state fair has been maintained at Springfield, chiefly for the benefit of the agricultural and horticultural interests. The fair grounds contain 156 acres, and the buildings were erected at great expense. The Dome Building, which is used for agricultural exhibits, has the dome from the Horticultural Hall of the World's Fair at Chicago in 1893. According to the census of 1890, the total acreage of farms in the state was 30,498,277; 25,669,060 were improved, and 4,829,217 unimproved. The number of farms cultivated by the owners was 158,848; the number rented for money was 29,182; the number rented for a share of the products was 52,651. The number of families occupying farms was 252,953, and of this number 160,065 owned their farms. The number of farms under 50 acres was 49,448; 50 and under 100, 68,746; 100 and under 500, 119,684; 500 and under 1000, 2420; 1000 and over, 383. The value of farm lands, fences, and buildings was $1,262,870,587; of farm implements and machinery, $34,456,938; of live stock, $180,431,662; of farm products, $184,759,013. The cost of fertilizers purchased, $124,977.

The United States Department of Agriculture gave the following statistics of the grain production of the state for 1900:—

	Wheat.	Oats.	Corn.	Barley.	Rye.	Buckwheat.	Potatoes.	Hay.
Acreage	1,383,236	3,516,918	7,139,898	13,365	73,877	4,476	166,262	1,668,834
Number of bushels .	17,982,068	133,642,884	264,176,226	342,144	1,270,684	67,140	15,296,104	2,119,419[1]
Average yield per acre	13·0	38·0	37·0	25·6	17·2	15·0	92	1·27[1]
Average value per acre	$8·32	$8·74	$11·84	$12·03	$8·08	$9·75	$37·72	$10·66
Value of crop . . .	$11,508,524	$30,737,863	$84,536,392	$160,808	$597,221	$43,641	$6,271,403	$17,803,120

The figures in the following table are of 1st January 1900:—

	Number.	Value.	Average Price per Head.
Milch cows .	1,021,236	$37,070,867	$36·30
Other cattle .	1,303,018	41,197,518	31·62
Sheep . . .	637,719	2,532,383	3·97

The beet-sugar crop is estimated at 1800 tons. The state is first among the states in the Union for the value of the crops of corn and oats, and of milch cows, and in the number of sheep and swine. It holds second place as to horses and meat cattle. Chicago is the greatest live-stock market in the world.

Manufactures.—In 1900 the state held third place in the Union as respects alike the value of its manufactured products, the cost of materials used, and capital invested. The following are the general statistics for 1890 and 1900:—

	1890.	1900.	Per cent. of Increase.
Number of establishments . . .	20,482	38,360	87·3
Capital . . .	$502,004,512	$776,829,598	54·7
Wage-earners, average number . .	280,218	395,110	41·0
Total wages . .	$142,873,265	$191,510,962	34·0
Cost of materials used	$529,019,089	$739,754,414	39·8
Value of products .	$908,640,280	$1,259,571,105	38·6

The most important of the different manufacturing industries was that of slaughtering and meat-packing, with 64 establishments, an aggregate capital of $71,229,262, 27,861 wage-earners (besides salaried officials, clerks, &c.), and products valued at $287,922,277. The size of other leading industries in 1900 is shown by the following table:—

Industry.	Establishments.	Wage-earners.	Value of Products.
Agricultural implements . . .	94	18,231	$42,033,796
Cars, steam railway .	17	9,314	24,845,606
Clothing, men's .	900	14,977	37,378,717
Flouring and grist mill products .	871	2,111	31,006,294
Foundry and machine-shop products .	758	31,851	63,878,352
Iron and steel . .	26	16,642	60,144,081
Liquors, distilled and malt . . .	114	3,607	57,941,897

Railways.—Illinois holds first place in railway mileage. The State Railway and Warehouse Commission reported, 30th June 1900, for steam railways in Illinois a total mileage of 10,817·10 main line and branches; total capital per mile, $63,172; total income of passenger department, including mails and express, $25,458,150; freight income, $69,510,827; total earnings and

[1] Number of tons.

income, $107,806,152; total expenditures, $93,072,220; passengers carried, 42,153,557; passenger earnings per mile of road, $2914; tons of freight carried, 83,667,441; freight earnings per mile, $5990; railway employees, 88,047; aggregate amount paid to employees, $51,360,689; tons of steel rails laid during year, 120,194; number of stations, 2761; passengers killed, 12, injured, 137; employees killed, 199, injured, 2122; trespassers killed, 503, injured, 490; taxes paid by railways, $4,379,611. Total mileage of elevated and inter-urban lines was 14,968; capital, $83,067,300; income, $4,248,286; and passengers carried, 74,415,958.

Insurance.—In 1893 the insurance department, formerly a part of the State Auditor's office, became a separate state department under the control of a superintendent appointed by the governor, subject to confirmation by the Senate. The number of life insurance companies entitled to do business in Illinois, 31st December 1899, was 45. Their total assets were $1,590,891,959; liabilities, $1,363,246,210; surplus, $227,645,748. The number of fraternal beneficiary societies authorized to do business was 94. Their admitted assets, $14,290,653; and their unadmitted assets, $959,409. Their liabilities were $5,575,598. The number of assessment life associations was 30. Their total income for 1899 was $14,460,090; total disbursements, $11,179,096. Admitted assets were $12,966,243; unadmitted, $1,736,616. Their total liabilities were $6,325,464. The number of assessment accident associations was 8. The number of fire and marine insurance companies was 203; 23 were mutual companies, 48 foreign, having branches in the United States, and 126 were joint-stock companies of other states. The net cash surplus of the fire and marine insurance companies authorized to do business in Illinois in 1900 was, 31st December 1899, $97,812,478; their income, $164,217,137; expenditures, $166,109,193.

Coal.—In amount of bituminous coal mined the state holds second place. For the year ending 30th June 1900 there were fifty-two counties producing coal. The total number of mines was 920, but of this number only 323 were shipping mines. The total output of all mines in tons of 2000 pounds was 25,153,929. The aggregate home value of the total product was $22,510,360. The total number of persons employed was 39,384, of whom 35,203 were at work underground. The number of men accidentally killed was 95, and the number injured so as to lose a week or more of time, 61. The average days of active operations for shipping mines was 214. The number of mines in which mining machines were used was 65, and the number of mining machines in use was 430. The average value per ton, all grades at the mine, was $0·8949. The chief mining counties are Vermilion, Sangamon, La Salle, St Clair, Macoupin, Madison, Bureau, Grundy, and Williamson. A revised mining law became operative 1st July 1899. All mines are required to be in charge of certificated mine managers, mine examiners, and hoisting engineers, where the services of the last-mentioned class are necessary. The number of men permitted to work in any mine not having an escapement cannot in any circumstances exceed ten, and then only for the purpose of completing the escapement. The state is divided into seven inspection districts, and there are seven state mine inspectors appointed by the governor.

Banks.—The number of national banks on 13th December 1900 was 242. The amount of capital stock paid in was $35,996,900. Their surplus fund was $14,852,722; and undivided profits, $8,371,563. The amount of deposits was $191,236,702; and reserve held, $55,770,808. In 1887 Illinois for the first time passed an Act providing for the organization of savings-banks. The number of state banks in operation, 14th December 1900, was 155.

Debt.—On 1st November 1900, and for a number of years prior thereto, the principal of the bonded debt outstanding has been $18,500. These bonds ceased to draw interest 1st January 1882, and although called in by the governor, have never been presented for payment. The state constitution prohibits the state from loaning its credit or making appropriations in aid of railways or canals, and a similar prohibition is placed on counties, cities, towns, and other municipalities. Neither can the state loan its credit to, or in aid of, any public or other corporation, association, or individual. The state may, to meet casual deficits, contract debts not to exceed in the aggregate $250,000; and no other debt, except for repelling invasion, suppressing insurrection, or defending the state in war, can be contracted until submitted to a vote of the people and approved by a majority of the votes cast. No county, city, township, school district, or other municipal corporation can incur indebtedness exceeding 5 per cent. on the value of the taxable property. In 1890, 46 of the 103 counties of the state were free from debt.

Revenues and Taxation.—Receipts in the state treasury from all sources from 1st October 1898 to 30th September 1900 were $16,645,925; disbursements for the same period were $14,027,970. The balance in the state treasury, 1st October 1900, was $2,617,955. Under charter of the Illinois Central Railway that company is bound to pay into the state treasury semi-annually 7 per cent. of its gross annual earnings, and is relieved from all other taxes on its property. The state has received from the company, 30th April 1900 inclusive, $18,392,243. The inheritance tax brought to the state treasury, from 1st October 1898 to 30th September 1900, $958,785. The total value of all property assessed for taxes for 1899, as fixed by the State Board of Equalization, was $953,099,468. Total number of horses assessed in 1899 was 1,222,048, value $10,127,085; cattle, 2,256,759, value $11,350,995; mules and asses, 108,458, value $957,769; sheep, 630,677, value $453,729; hogs, 2,730,652, value $2,285,546. The assessed value of railway property was $79,072,674. The equalized value of personal property was $183,526,987; of town and city lots, $373,742,282; railway personal property, $1,789,666; railway lands, $222,010; railway town and city lots, $1,048,956.

Churches.—The number of church organizations within the state, census 1890, was 8296; the number of church edifices, 7352; the seating capacity, 2,260,619; the value of church property, $39,715,245; the number of communicants, 1,202,588; the percentage of population, 31·43. Church membership was divided as follows: Catholics, 475,474; Methodists, 189,358; Baptists, 109,640; Presbyterian, 77,213; Lutheran, 116,807; Disciples of Christ, 60,867; Protestant Episcopal, 20,854; Congregational, 35,830. In respect of the value of church property the state ranked fourth.

Population.—Illinois ranks third in population among the states of the Union, under the census of 1900. The population was 4,821,550, and the gain for the decade was 995,199. The numerical increase was greater than in any previous decade of the state's history. The gain in the previous decade was 748,480. The number of males was 2,472,782, and females 2,348,768. The number of native-born was 3,854,803, and of foreign-born 966,747. The total white population was 4,734,873, the native white population was 3,770,238. The average number of persons to the square mile, under the census of 1900, was 86·0; and under that of 1890, 68·3. The number of males of voting age in 1900 was 1,401,456. Of this number 932,574 were native-born and 468,882 foreign-born; 1,370,209 were white, and 31,247 coloured. There were 29 cities in 1890 having a population exceeding 5000, and 51 in 1900. Of the 930 incorporated cities, towns, and villages in the state in 1900, 614 had less than 1000 inhabitants; 878 less than 5000; 27 more than 5000, but less than 10,000; 14 more than 10,000, but less than 20,000; 4 more than 20,000, but less than 25,000; and 7 more than 25,000. These seven with their populations were as follows:—

Chicago	1,698,575
Peoria	56,100
Quincy	36,252
Springfield	34,159
Rockford	31,051
East St Louis	29,655
Joliet	29,353

(H. W. R.)

Illustration.—In a general sense illustration is as old as Art itself. There has never been a time since civilization began when artists were not prompted to pictorial themes from legendary, historical, or literary sources. But the art of illustration, as now understood, is a comparatively modern product. The tendency of modern culture has been to make the interests of the different arts overlap. The theory of Wagner, as applied to opera, for making a combined appeal to the artistic emotions, has been also the underlying principle in the development of that great body of artistic production which in painting gives us the picture containing "literary" elements, and, in actual association with literature in its printed form, becomes what we call "illustration." The illustrator's work is the complement of expression in some other medium. A poem can hardly exist which does not awaken in the mind at some moment a suggestion either of picture or music. The sensitive temperament of the artist or the musician is able to realize out of words some parallel idea which can only be conveyed, or can be best conveyed, through his own medium of music or painting. Similarly, music or painting may, and often does, suggest poetry. It is from this inter-relation of the emotions governing the different arts that illustration may be said to spring. The success of illustration lies, then, in the instinctive transference of an idea from one medium to another; the more spontaneous it be and the less laboured in application, the better. But when this

common ground has been stated, it must be recognized that illustration introduces a fresh personality, and, therefore, the risk of departure in feeling from the idea which was in the writer's mind. There is this drawback appertaining to illustration—that while, as art, it may be fine, as illustration it may be very imperfect. So, also, does the converse hold good. Thus the *Bab Ballads* and the *Ingoldsby Legends* have been more adequately illustrated than the works of Shakespeare. But if to illustrate is a natural artistic impulse, the freedom of the artist to a large extent follows. The written word remains unchanged, and the illustrations may be taken apart from their context. It is only a particular edition, and not the literary essence of a book, that illustration can damage.

Leaving on one side the illuminated manuscripts of the Middle Ages, which have been treated in the ninth edition of this work under ILLUMINATION, we start with the fact that illustration in the accepted sense was coincident with the invention of printing. Italian art produced many fine examples, notably the outline illustrations to the *Poliphili Hypnerotomachia*, printed by Aldus at Venice in the last year of the 15th century. Other early works exist, the products of unnamed artists of the French, German, Spanish, and Italian schools; while of more singular importance, though not then brought into book form, were the illustrations to Dante's *Divine Comedy* made by Botticelli at about the same period. The sudden development of engraving on metal and wood drew many painters of the Renaissance towards illustration as a further opportunity for the exercise of their powers; and the line-work, either original or engraved by others, of Pollajuolo, Mantegna, Michelangelo, and Titian (to name only a few) has its place in the gradual enlargement of illustrative art. The German school of the 16th century committed its energies even more vigorously to illustration; and many of its artists are now known chiefly through their engravings on wood or copper, a good proportion of which were done to the accompaniment of printed matter. The names of Dürer, Burgmair, Altdorfer, and Holbein represent a school whose engraved illustrations possess qualities which have never been rivalled, and remain an invaluable aid to imitators of the present day.

Illustration has generally flourished in any particular age in proportion to the health and vigour of the artistic productions in other kinds. No evident revival in painting has come about, no great school has existed during the last four centuries, which has not set its mark upon the illustration of the period and quickened it into a medium for true artistic expression. The etchers of the Low Countries during the 17th century, with Rembrandt at their head, were to a great extent illustrators in their choice of subjects. In France the period of Watteau and Fragonard gave rise to a school of delicately engraved illustration, exquisite in detail and invention. In England Hogarth came to be the founder of many new conditions, both in painting and illustration, and was followed by men of genius so distinct as Reynolds on the one side and Bewick on the other. With Reynolds one connects the illustrators and engravers for whom now Bartolozzi supplies a surviving name and an embodiment in his graceful but never quite English art. But it is from Bewick that the wonderfully consistent development of English illustration begins to date. Bewick marks an important period in the technical history of wood-engraving as the practical inventor of the "tint" and "white line" method of wood-cutting; but he also happened to be an artist. His artistic device was to give local colour and texture without shadow, securing thereby an altogether novel amount of truth, side by side with a precision of outline which allowed no form to be lost. And though, in consequence, many of his best designs have somewhat the air of a specimen plate, he succeeded in bringing into black-and-white illustration an element of colour which had been wholly absent from it in the work of the 15th and 16th century German and Italian schools. Bewick's method started a new school; but the more racy qualities of his woodcuts were entirely dependent on the designer being his own cutter; and the same happy relationship gave distinct characteristics to the nearly contemporary work of Blake and of Calvert. Blake's wonderful *Illustrations to the Book of Job*, while magnificent in their conventional rendering of light and shade, still retain the colourlessness of the old masters, as do also the more broadly handled designs to his own books of prophecy and verse; but in his woodcuts to Philips's *Pastorals* the modern tendency towards local colour makes itself strongly felt. So wonderfully, indeed, have colour and tone been expressed in these rough wood-blocks, that more vivid impressions of darkness and twilight falling across quiet landscape have never been produced through the same materials. The pastoral designs made by Edward Calvert on similar lines can hardly be over-praised. Technically these engravings are far more able than those from which they drew their inspiration.

Progress in England.

With the exception of the two artists named, and in a minor degree of Stothard and Flaxman, who also produced original illustrations, the period from the end of the 18th century till about the middle of the 19th was less notable for the work of the designer than of the engraver. The delicate plates to Rogers's *Italy* were done from drawings which Turner had not produced for purposes of illustration; and the admirable lithographs of Prout and Bonington were merely studies of architecture and landscape made in a material that admitted of indefinite multiplication. It is true that Géricault came over to England about the year 1820 to draw the English race-horse and other studies of country life, which were published in London in 1821, and that other fine work in lithography was done by James Ward, G. Cattermole, and somewhat later by J. F. Lewis. But illustration proper, subject-illustration applied to literature, was mainly in the hands of the wood-engravers; and these, forming a really fine school founded on the lines which Bewick had laid down, had for about thirty years to content themselves with rendering the works of ephemeral artists, among whom Haydon and Martin stand out as the chief lights. It must not be forgotten, however, that while the day of a serious English school of illustration had not yet come, Great Britain possessed an indigenous tradition of gross and lively caricature; a tradition of such robust force and vulgarity that, by the side of some choicer specimens of Gillray and Bunbury, the art of Rowlandson appears almost refined. This was the school in which George Cruikshank, John Leech, and the Dickens illustrators had their training, from which they drew more and more away; until, with the help of *Punch*, just before the middle of the 19th century, English caricaturists had learned the secret, which in France has not yet been discovered, of how to be apposite and amusing without scurrility and without libel.

It was in about the year 1832 that the illustrated weekly paper started on its career in England, and almost by accident determined under what form a great national art was to develop itself. While in France the illustrators were making their triumphs by means of lithography, English illustration was becoming more and more identified with wood-engraving. The demand for a method of illustration, easy to produce and easy to print, for books

and magazines of large circulation and moderate price, forced the artist before long into drawing upon the wood itself; and so soon as the artist had asserted his preference for facsimile over "tint," the school which came to be called "of the 'sixties" was in embryo, and waited only for artistic power to give it distinction. The engraver's translation of the artist's painting or wash-drawing into "tint" had largely exalted the individuality of the engraver at the expense of the artist. But from the moment when the designer began to put his own lines upon the wood, new conditions shaped themselves; and though the artist at times might make demands which the engraver could not follow, or the engraver inadequately fulfil the expectation of the artist, the general tendency was to bring designer and engraver into almost ideal relations—an ideal which nothing short of the artist being his own engraver could have equalled. Out of an alliance cemented by their common use and understanding of the material on which they worked came the school of facsimile or partial-facsimile engraving which flourished during the 'sixties, and lasted just so long as its conditions were unimpaired—losing its flavour only at the moment when "improved" mechanical appliances enabled the artist once more to dissociate himself from the conditions which bound the engraver in his craft.

Influence of wood-engraving.

Before the fortunate circumstances which governed the work of the 'sixties became decisive, illustrations of a transitional character but tending to the same end had been produced by John Tenniel, John Gilbert, Birket Foster, Harrison Weir, T. Creswick, W. Mulready, and others; but their methods were too vague and diffuse to bear as yet the mark of a school; no single influence gave a unity to their efforts. On some of them Menzel's illustrations to Kügler's *Frederick the Great*, published in England in 1844, may have left a mark: Gilbert certainly shows traces of the influence of Delacroix and Bonington in the free, loose method of his draughtsmanship, independent of accurate modelling, and with here and there a paint-like dab of black to relieve a generally colourless effect; while Tenniel, with cold, precise lines of wire-drawn hardness, remained the representative of the past academic style, influencing others by the dignity of his fine technique, but with his own feeling quite untouched by the Pre-Raphaelite and romantic movement which was soon to occupy the world of illustration. In greater or less degree it may be said of the work of all these artists that, as it antedates, so to the end does it stand somewhat removed in character from, the school with which for a time it became contemporary. The year which decisively marked the beginning of new things in illustration was 1857, the year of the Moxon *Tennyson* and of Wilmott's *Poets of the Nineteenth Century*, with illustrations by Rossetti, Millais, Holman Hunt, and Ford Madox Brown. In these artists we get the germ of the movement which afterwards came to have so wide a popularity. At the beginning, Pre-Raphaelite in name, poetic and literary in its choice of subjects, the school quickly expanded to an acceptance of those open-air and everyday subjects which one connects with the names of Walker, Houghton, Pinwell, and North. The illustrations of the Pre-Raphaelites were eminently thoughtful, full of symbolism, and with a certain pressure of interest to which the epithet of "intense" came to be applied. As an example of their method of thought-transference from word to form, Madox Brown's drawing for the Dalziel Bible of "Elijah and the Widow's Son" may be taken. The restoration of life to a dead body, of a child to its mother, is there conveyed with many illustrative touches and asides, which become clumsy when stated in words. The hen bearing her chicken between her wings is a perfectly direct and appropriate pictorial symbol, but a far more imaginative stroke is the shadow on the wall of a swallow flying back to the clay bottle where it has made its nest. Here is illustration full of literary symbolism, yet wholly pictorial in its means; and in this it is entirely characteristic of Pre-Raphaelite feeling, with its method of suggesting, through externals, consideration as opposed to mere outlook. Of this phase Rossetti must be accounted the leader, but it was Millais who, by the sheer weight of his personality, carried English illustration along with him from Pre-Raphaelitism to the freer romanticism and naturalistic tendencies of the 'sixties. Rossetti, with his poetic enthusiasm, his strong personal magnetism, and dramatic power of composition, may be said to have brought about the awakening; it was Millais who, by his rapid development of style, his original and daring technique, turned it into a movement. When he started, there were many influences behind him and his fellow-workers—among older foreign contemporaries, those of Menzel and Rethel; and behind these again something of the old masters. But through a transitional period, represented by his twelve drawings of "The Parables," which appeared first in *Good Words*, Millais emerged into the perfect independence of his illustrations to Trollope's novels, *Framley Parsonage* and *The Small House at Allington*, his own master and the master of a new school. Depicting the ugly fashions of his day with grave dignity and distinction, and with a broad power of rendering type in work which had the aspect of genre, he drew the picture of his age in a summary so embracing that his illustrations attain the rank almost of historical art. For art of this sort the symbolism of the Pre-Raphaelites lost its use: the realization in form of a character conveyed by an author's words, the happy suggestion of a locality helping to fix the writer's description, the verisimilitudes of ordinary life, even to trivial detail, carried out with real pictorial conviction, were the things most to be aimed at. Pictorial conviction was the great mark of the illustrative school of the 'sixties. The work of its artists has absorbed so completely the interest and reality of the letterpress that the results are a model of what faithful yet imaginative illustration should be. In the illustrated magazines of this period, *Once a Week*, *Good Words*, *Cornhill*, *London Society*, *The Argosy*, *The Leisure Hour*, *Sunday at Home*, *The Quiver*, and *The Churchman's Family Magazine*, as well as others, is to be found the best work of this new school of illustrators; and with the greater number of them it cannot be mistaken that Millais is the prevailing force.

Pre-Raphaelite movement.

Influence of Millais.

By their side other men were working, more deeply influenced by the old masters, and by the minuteness and hard, definite treatment of form which the Pre-Raphaelite school had inculcated. Foremost of these was Frederick Sandys, a draughtsman of great technical power, precise in outline and detail. His method shows a blend of the styles of Dürer, Holbein, and Rethel, with an acceptance of the more modern devices which suggest colour and tone. His illustrations, scattered through nearly all the magazines which have been named, show always a decorative power of design, and are full of fine drawing and fine invention, but remain resolutely cold in handling and lacking in imaginative ardour. The few illustrations done by Burne-Jones at this period show a whole-hearted following of Rossetti, but a somewhat struggling technique; and the same qualities are to be found in the work of Arthur Hughes, whose illustrations in *Good Words for the Young* (1869) have a charm of tender poetic invention showing through the faults and persistent uncertainty of his draughtsmanship. Higher technical

qualities single out the work of Frederick Shields for notice: his illustrations to Defoe's *History of the Plague* have a certain affinity to the work of Sandys; but, with less power over form, they show a more dramatic sense of light and shade, and at their best can claim real and original beauty. The formality of feeling and composition, and the strained, stiff quality of line in Lord Leighton's designs to *Romola* (1863), do a good deal to mar one's enjoyment of their admirable draughtsmanship. Many fine drawings done at this period by Leighton, Poynter, Armstead, and Burne-Jones, characterized by fine, hard draughtsmanship and close cross-hatching, did not appear until the year 1880 in the "Dalziel Bible Gallery," when the methods of which they were the outcome had fallen almost out of use.

Deeply influenced by the broad later phases of Millais's black-and-white work were those artists whose tendency lay in the direction of idyllic naturalism and popular romance, the men to whom more particularly is given the name of the period and school "the 'sixties," and whose more immediate leader, as far as popular estimation goes, was Frederick Walker. With his, one may roughly group the names of Pinwell, Houghton, North, Keene, Lawless, Mahoney, Morten, and, with a certain reservation, W. Small and G. du Maurier. In no very separate category stand two other artists whose contributions to illustration were but incidental, John Pettie and J. M'Neill Whistler. The broad characteristics of this variously related group were a loose, easy line suggestive of movement, a general fondness for white spaces and open-air effects, and in the best of them a thorough sense of the serious beauty of domestic and rural life. They treated the present with a feeling rather idyllic than realistic; when they touched the past it was with a courteous sort of realism, and a wonderful inventiveness of detail which carried with it a curious charm of conviction. Walker's method shows a broad and vivid use of black and white, with a fine sense of balance, but very little preoccupation for decorative effect. Pinwell had a more delicate fancy, but less freedom in his technique—less ease, but more originality of composition. In Houghton's work one sees a swift, masterful technique, full of audacity, noble in its economy of means, sometimes rough and careless. His temperament was dramatic, passionate, satiric, and witty. Some of his best work, his "Scenes from American Life," appeared in the pages of the *Graphic* as late as the years 1873–74. There are indications in the work of Lawless that he might have come close to Millais in his power of infusing distinction into the barest materials of everyday life, but he died too soon for his work to reach its full accomplishment. North was essentially a landscape illustrator, notable for the dignity and sense of subject he was able to infuse into compositions which were without figure interest. The delicate sense of beauty in du Maurier's early work became lost in the formal but graceful conventions of his later *Punch* drawings. It was in the pages of *Punch* that Keene, the greatest impressionist illustrator England has produced, secured his chief triumphs. The two last-named artists outstayed the day which saw the break-up of the school of which these are the leading names. It ran its course through a period when illustrated magazines formed the staple of popular consumption, before the illustrated newspapers, with their hungry rush for the record of latest events, became a weekly feature. Its waning influence may be plainly traced through the early years of the *Graphic*, which started in 1869 with some really fine work, done under transitional conditions before the engraver's rendering of tone-drawings once more ousted facsimile from its high place in illustration.

"The 'Sixties."

In connexion with this transitional period, drawings for the *Graphic* by Houghton, Pinwell, Herkomer, E. J. Gregory, H. Woods, Charles Green, H. Paterson (Mrs Allingham), and William Small deserve honourable mention. Yet it was the last-named who was mainly instrumental in bringing about the change from line-work to pigment, which, by removing the limitations that had flavoured the artist's work and made it native to its environment, depressed the artistic value of illustration during the 'seventies and the 'eighties to almost absolute mediocrity. Several artists of great ability practised illustration during this period: in addition to those *Graphic* artists already mentioned there were Luke Fildes, Frank Holl, S. P. Hall, Paul Renouard, and a few others of smaller merit. But the interest was for the time shifting from black-and-white work and turning to colour. Kate Greenaway began to produce her charming idyllic renderings of children in mob-caps and long skirts delicately outlined and tinted. Walter Crane on somewhat similar lines designed his illustrated nursery rhymes, *Baby's Opera*, *Baby's Bouquet*, and the like; while Randolph Caldecott took the field with his fresh and breezy scenes of hunting life and carousal in the times most typical of the English squirearchy. Working with a broad outline, suggestive of the brush by its easy freedom, and adding washes of conventional colour for embellishment, he was one of the first in England to show the beginnings of Japanese influence. Even more dependent upon colour were his illustrated books for children; while in black and white, in his illustrations to *Bracebridge Hall* (1876), for instance, pen and ink began to replace the pencil, and to produce a new and more independent style of draughtsmanship. This style, clear and straightforward but without much subtlety, was taken up and followed by many artists of ability, by Harry Furniss, Hugh Thomson, and others, till the influence of E. A. Abbey's more mobile and more elaborate penmanship came to produce a still further development in the direction of fineness and illusion, and that of Phil May, with Linley Sambourne for his teacher, to simplify and make broad for those who aimed rather at a journalistic and shorthand method of illustration. (See also CARICATURE and CARTOON.)

Under the absolutely liberating conditions of "process reproduction" (see PROCESS) the latest developments in illustration on its lighter and more popular side are full of French influences, or ready to follow the wind in any fresh direction, whether to America or Japan; but on the graver side they show a strong leaning towards the older traditions of the 'sixties and of Pre-Raphaelitism. It would be rash from the random and often undistinguished cleverness of the popular school to select names which may have very little permanent standing: the title of the weekly paper which started them on a prosperous career, the *Sketch*, will indicate where their works may be found and their style studied, just as in the first volume of *Black and White* may be seen the one serious attempt to revive in connexion with a weekly publication a worthier and less flighty tradition of illustration. A more successful motive force in that direction came from the founding by William Morris of the Kelmscott Press in 1891 (see WILLIAM MORRIS, and BOOK-PRINTING), through which were produced a series of decorated and illustrated books which aimed frankly at a revival of mediæval taste. In Morris's books decorative effect and sense of material claimed mastery over the whole scheme, and subdued the illustrations to a sort of glorious captivity into which no breath of modern spirit could be breathed. The illustrations of Burne-Jones filled with a happy touch of archaism the decorative borders of William Morris; and only a little less happy, apart from their imaginative inferiority, were the serious efforts of Walter Crane and one or two others to fulfil the requirements of pages which would not abate a decade of their mediæval standpoint to fit with more nicety the requirements of the illustrator. Directly under the Morris influence arose the "Birmingham school," with an entire devotion to decorative methods and still archaic effects which tended sometimes to rather inane technical results. Among its leaders may be named Arthur Gaskin, C. M. Gere, and E. H. New; while work

Contemporary illustrators.

not dissimilar but more independent in spirit had already been done by Selwyn Image and H. P. Horne in the *Century Guild Hobby-Horse*. But far greater originality and force belonged to the work of a group, known for a time as the neo-Pre-Raphaelites, which joined to an earnest study of the past a scrupulously open mind towards more modern influences. Its earliest expression of existence was the publication of an occasional periodical, the *Dial* (1889 to 1897), but before long its influence became felt outside its first narrow limits. The technical influence of Abbey, but still more the emotional and intellectual teaching of Rossetti and Millais, together with side-influences from the few great French symbolists, were, apart from their own originality, the forces which gave distinction to the work of C. S. Ricketts, C. H. Shannon, R. Savage, and their immediate following. Beauty of line, languorous passion, symbolism full of literary allusions, and a fondness for the life of any age but the present, are the characteristics of the school. Their influence fell very much in the same quarters where Morris found a welcome; but an affinity for the Italian rather than the German masters (shown especially in the "Vale Press" publications), and a studied note of world-weariness, kept them somewhat apart from the sturdy mediævalism of Morris, and linked them intellectually with the decadent school initiated by the wayward genius of Aubrey Beardsley. But though broadly men may be classed in groups, no grouping will supply a formula for all the noteworthy work produced when men are drawn this way and that by current influences. Among artists resolutely independent of contemporary coteries are W. Strang, whose grave, rugged work shows him a pupil, through Legros, of Dürer and others of the old masters; T. Sturge Moore, an original engraver of designs which have an equal affinity for Blake, Calvert, and Hokusai; W. Nicholson, whose style shows a dignified return to the best part of the Rowlandson tradition; and E. J. Sullivan. Among decorative and romantic illustrators of no particular school may be named G. Moira, Byam Shaw, Anning Bell, R. Spence, Mary S. Florence, J. D. Batten, Patten Wilson, and C. Robinson—all artists of considerable inventive faculty, but of rather irresolute imagination and style. In the closing years of the 19th century Aubrey Beardsley became the creator of an entirely novel style of decorative illustration. Drawing inspiration from all sources of European and Japanese art, he produced, by the force of a vivid personality and extraordinary technical skill, a result which was highly original and impressive. To a genuine liking for analysis of repulsive and vicious types of humanity he added an exquisite sense of line, balance, and mass; and partly by *succès de scandale*, partly by genuine artistic brilliance, he gathered round him a host of imitators, to whom, for the most part, he was able to impart only his more mediocre qualities.

United States.

In America, until a comparatively recent date, illustration bowed the knee to the superior excellence of the engraver over the artist. Not until the brilliant pen-drawing of E. A. Abbey carried the day with the black-and-white artists of England did any work of real moment emanate from the United States, unless that of Elihu Vedder be regarded as an exception. Even now it has no school of illustration properly so called, but its leading magazines contain work of individual power which cannot be overlooked. Howard Pyle is a brilliant imitator of Durer; he has also the ability to adapt himself to draughtsmanship of a more modern tendency. C. S. Reinhart was an artist of directness and force, in a style based upon modern French and German examples; while of greater originality as a whole, though derivative in detail, is the fanciful penmanship of Alfred Brennan. Other artists who stand in the front rank of American illustrators, and whose works appear chiefly in the pages of *Scribner's*, *Harper's*, and the *Century Magazine*, are W. T. Smedley, F. S. Church, R. Blum, Wenzell, A. B. Frost, and in particular C. Dana Gibson, the last of whom has gained a reputation in England as an American du Maurier.

France.

The record of modern French illustration goes back to the day when political caricature and the Napoleonic legend divided between them the triumphs of early lithography. The illustrators of France at that period were also her greatest artists. Of the historical and romantic school were Raffet, Charlet, Géricault, Delacroix, Isabey, and Achille Devéria, many of whose works appeared in *L'Artiste*, a paper founded in 1831 as the official organ of the romanticists; while the realists were led in the direction of caricature by two artists of such enormous force as Gavarni and Daumier, whose works, appearing in *La Lithographie Mensuelle*, *Le Charivari*, and *La Caricature*, ran the gauntlet of political interference and suppression during a troubled period of French politics—which was the very cause of their prosperity. Behind these men lay the influence of the great Spanish realist Goya. Following upon the harsh satire and venomous realism of this famous school of pictorial invective, the influence of the Barbizon school came as a milder force; but the power of its artists did not show in the direction of original lithography, and far more value attaches to the few woodcuts of J. F. Millet's studies of peasant life. In these we see clearly the tendency of French illustrative art to keep as far as possible the authentic and sketch-like touch of the artist; and it was no doubt from this tendency that so many of the great French illustrators retained lithography rather than commit themselves to the middleman engraver. Nevertheless, from about the year 1830 many French artists produced illustrations which were interpreted upon the wood for the most part by English engravers. Cunier's editions of *Paul et Virginie* and *La Chaumière Indienne*, illustrated by Huet, Jacque, Isabey, Johannot, and Meissonier, were followed by Meissonier's more famous illustrations to *Contes Rémois*. After Meissonier came Detaille and De Neuville, and, with a voluminous style of his own, Doré. By the majority of these artists the drawing for the engraver seems to have been done with the pen; and the tendency to penmanship was still more accentuated when from Spain came the influence of Fortuny's brilliant but restless technique; while after him, again, came Vierge, to make, as it were, the point of the pen still more pointed. During the middle period of the 19th century the best French illustration was serious in character; but among the later men, when we have recognized the grave beauty of Grasset's *Les Quatre Fils d'Aymon* (in spite of his vicious treatment of the page by flooding washes of colour through the type itself), and the delicate grace of Boutet de Monvel's *Jeanne d'Arc*, also in colours, it is to the illustrators of the comic papers that we have to go for the most typical and most audacious specimens of French art. In the pages of *Gil Blas*, *Le Pierrot*, *L'Écho de Paris*, *Le Figaro Illustré*, *Le Courrier Français*, and similar publications, are to be found, reproduced with a dexterity of process unsurpassed in England, the designs of Forain, Léandre, Willette, and Steinlen, the leaders of a school enterprising in technique, and with a mixture of subtlety and grossness in its humour. Caran d'Ache is also well known as a draughtsman of comic drama in outline.

Germany.

Among illustrators of Teutonic race the one artist who seems worthy of comparison with the great Menzel is Hans Tegner, if, indeed, he be not in some respects his technical superior; but apart from these two, the illustrators respectively of Kügler's *Frederick the Great* and Holberg's *Comedies*, there is no German, Danish, or Dutch illustrator who can lay claim to first rank. Max Klinger, A. Böcklin, W. Trübner, Franz Stück, and Hans Thoma are all symbolists who combine in a singular degree force with brutality; the imaginative quality in their work is for the most part ruined by the hard, braggart way in which it is driven home. The achievements and tendency of the present school of illustration in Germany are best seen in the weekly illustrated journal, *Jugend*, of Munich. Typical of an older German school is the work of Oberländer, a solid, scientific sort of caricaturist, whose illustrations are at times so monumental that the humour in them seems crushed out of life. Others who command high qualities of technique are W. Dietz, L. von Nagel, Hermann Vogel, H. Lüders, and Robert Haug. Behind all these men in greater or less degree lies the influence of Menzel's coldly balanced and dry-lighted realism; but wherever the influence of Menzel ceases, the merit of German illustration for the most part tends to disappear or become mediocre.

TECHNICAL DEVELOPMENTS.

The history of illustration, apart from the merits of individual artists, during the period since the year 1875, is mainly that of the development of what is called Process (*q.v.*), the term applied to methods of reproducing a drawing or photograph which depend on the use of some mechanical agency in the making of the block, as distinguished from such products of manual skill as steel or wood engraving, lithography, and the like. There is good reason to believe that the art of stereotyping—the multiplication of an already existing block by means of moulds and casts—is as old as the 15th century; and the early processes were, in a measure, a refinement upon this: with the difference that they aimed at the making of a metal block by means of a cast of the lines of the drawing

itself, the background of which had been cut away so as to leave the design in a definite relief. Experiments of this nature may be said to have assumed practical shape from the time of the invention of Palmer's process called at first *Glyphography*, about the year 1844; this was afterwards perfected and used to a considerable extent under the name of *Dawson's Typographic Etching*, and its results were, in many cases, quite admirable, and often appear in books and periodicals of the first part of the period with which we are now concerned. The *Graphic*, for instance, published its first process block in 1876, and the *Illustrated London News* also made similar experiments at about the same time.

From this time begins the gradual application of photography to the uses of illustration, the first successful line blocks made by its help being probably those of Gillot, at Paris, in the early 'eighties. The next stage was to be the invention of some means of reproducing wash drawings. To do this it was necessary for the surface of the block to be so broken up that every tone of the drawing should be represented thereon by a grain holding ink enough to reproduce it. This was finally accomplished by the insertion of a screen, in the camera, between the lens and the plate—the effect of which was to break up the whole surface of the negative into dots, and so secure, when printed on a zinc plate and etched, an approximation to the desired result. Half-tone blocks (as they were called) of this nature (see PROCESS) were used in the *Graphic* from 1884 and the *Illustrated London News* from 1885 onwards, the methods at first in favour being those of Meisenbach and Boussod Valadon and Co.'s phototype. Lemercier and Petit of Paris, Angerer and Göschl of Vienna, and F. Ives of Philadelphia also perfected processes giving a similar result, a block by the latter appearing in the *Century* magazine as early as 1882. Processes of this description had, however, been used for some years before by Henry Blackburn in his *Academy Notes*.

During the decade 1875–85, however, the main body of illustration was accomplished by wood-engraving, which a few years earlier had achieved such splendid results. Its artistic qualities were now at a rather low ebb, although good facsimile engravings of pen-drawings were not infrequent. The two great illustrated periodicals already referred to during that period relied more upon pictorial than journalistic work. An increasing tendency towards the illustration of the events of the day was certainly shown, but the whole purpose of the journal was not, as at present, subordinated thereto. The chief illustrated magazines of the time, *Harper's*, the *Century*, the *English Illustrated*, were also content with the older methods, and are filled with wood-engravings, in which, if the value of the simple line forming the chief quality of the earlier work has disappeared, a most astonishing delicacy and success were obtained in the reproduction of tone.

Perhaps the most notable and most characteristic production of the time in England was colour-printing. The *Graphic* and the *Illustrated London News* published full-page supplements of high technical merit printed from wood-blocks in conjunction with metal plates, the latter sometimes having a relief aquatint surface which produced an effect of stipple upon the shading; metal was also used in preference to wood for the printing of certain colours. The children's books illustrated by Randolph Caldecott, Walter Crane, and Kate Greenaway at this time are among the finest specimens of colour-printing yet seen outside of Japan; in them the use of flat masses of pleasant colour in connexion with a bold and simple outline was carried to a very high pitch of excellence. These plates were generally printed by Edmund Evans. In 1887 the use of process was becoming still more general; but its future was by no means adequately foreseen, and the blocks of this and the next few years are anything but satisfactory. This, it soon appeared, was due to inefficient printing on the one hand, and, on the other, to a want of recognition by artists of the special qualities of drawing most suitable for photographic reproduction. The publication of Quevedo's *Pablo de Segovia* with illustrations by Daniel Vierge in 1882, although hardly noticed at the time, was to be a revelation of the possibilities of the new development; and a serious study of pen-drawing from this point of view was soon inaugurated by the issue of Joseph Pennell's *Pen Drawing and Pen Draughtsmen* in 1889, followed in 1892 by C. G. Harper's *English Pen Artists of To-day*, and in 1896 by Walter Crane's *Decorative Illustration of Books*. At this time also the influence of Aubrey Beardsley made itself strongly felt, not merely as a matter of style, but, by the use of simple line or mass of solid black, as an almost perfect type of the work most suitable to the needs of process. Wider experience of printing requirements, and finer workmanship in the actual making of the blocks, in Paris, Vienna, New York, and London, soon brought the half-tone process into great vogue. The spread of education has enormously increased the demand for ephemeral literature, more especially that which lends itself to pictorial illustration; and the photograph or drawing in wash reproduced in half-tone has of late to a great extent ousted line work from the better class of both books and periodicals.

Improvements in machinery have made it possible to print illustrations at a very high speed; and the facility with which photographs can now be taken of scenes such as the public delight to see reproduced in pictures has brought about an almost complete change in pictorial journalism. In addition, reference must be made to an extraordinary increase in the numbers and circulation of cheap periodical publications depending to a very large extent for popularity on their illustrations. Several of these, printed on the coarsest paper, from rotary machines, sell to the extent of hundreds of thousands of copies per week. It was inevitable that this cheapening process should not be permitted to develop without opposition, and the *Dial* (1889–97) must be looked on as a protest by the band of artists who promoted it against the unintelligent book-making now becoming prevalent. Much more effective and far-reaching in the same direction was the influence of William Morris, as shown in the publications of the Kelmscott Press (dating from 1891). In these volumes the aim was to produce illustrations and ornaments which were of their own nature akin to, and thus able to harmonize with the type, and to do this by pure handicraft work. As a result, a distinct improvement is to be found in the mere book-making of Great Britain; and although the main force of the movement soon spent itself in somewhat uninspired imitations, there can be no doubt of the survival of a taste for well-produced volumes, in which the relationship of type, paper, illustration, and binding has been a matter of careful and artistic consideration. Under this influence, a notable feature has been the re-issue, in an excellent form, of illustrated editions of the works of most of the famous writers.

Another significant outcome of the trend of popular education has been the rapid creation of a large literature devoted exclusively to art in one form or another. The *Art Journal* (1849), the *Magazine of Art* (1878), the *Studio* (1893), the *Artist* (in its illustrated form, 1895), and the *Connoisseur* (1901), as well as the considerable and important publications devoted to architecture and the like, have eagerly availed themselves of the new developments of illustration, and their pages have been the means of bringing before the public many experiments which might not otherwise have been tried. In addition to periodicals, large numbers of books of this nature are now issued, the cheapness and facility of the photographic processes making it possible to render treatises attractive to a much wider circle of readers than before, as well as to multiply evidence and example in a way that the older methods could never permit. But it is to be regretted that a large proportion of these—and indeed of most books of the day illustrated by half-tone blocks—are printed upon clay-faced paper, which it is believed cannot last many years.

The illustration of newspapers pure and simple is a matter of which we are probably only experiencing the beginnings of a great progress. *The Times* had occasionally published maps, but the printing of a portrait of Lefroy the murderer by the *Daily Telegraph* in 1881 was perhaps one of the earliest examples of journalistic enterprise in this direction. On 11th February 1895 the *Daily Chronicle* published an enlargement from a line drawing by Sir E. Burne-Jones, which was printed from a process line-block on a rotary machine; and since then illustrations of this kind are yearly becoming more frequent. They are generally in pure line, but the *Black and White Budget* has printed many half-tones in this manner.

In France the general movement has proceeded upon lines on the whole very similar. Process—especially what was called "Gillotage"—was adopted earlier, and used at first with greater liberality than in England, although wood-engraving has persisted effectively even up to our own time. The French have no periodicals which can compare with the *Daily Graphic*, or with the great illustrated weekly journals issued in the United Kingdom. Neither have they anything at all like the cheap and so-called "humorous" English papers. But in the various types of periodicals of which the *Revue Illustrée*, *Figaro Illustré*, and *Gil Blas Illustré* may be taken as examples, the most noticeable feature is a use of colour-printing, which is far in advance of anything generally attempted in Great Britain. A favourite and effective process is that employed for the reproduction of chalk drawings (as by Steinlen), which consists of the application of a surface-tint of colour from a metal plate to a print from an ordinary process block. *L'Illustration* still relies on older fashions, and publishes a considerable number of wood-engravings.

In Germany, *Jugend*, *Simplicissimus*, and other publications devoted to humour and caricature, employ colour-printing to a great extent with success. The organ of the artists of the younger German schools, *Pan* (1895), makes use of every means of illustration, and has especially cultivated lithography and wood-cuts, using these arts effectively but with some eccentricity. Holland

has also employed coloured lithography for a remarkable series of children's books illustrated by van Hoytema and others. The Viennese *Kunst und Kunsthandwerk* is an art publication which is exceptionally well produced and printed.

Illustration in the United States has some few characteristics which differentiate it from that of other countries. The later school of fine wood-engraving is even yet in existence. American artists also introduced an effective use of the process block, namely, the engraving or working over of the whole or certain portions of it by hand. This is generally done by an engraver, but in certain cases it has been the work of the original draughtsman, and its possibilities foreseen by him in making his drawing. The only other variant of note is the use of half-tone blocks superimposed for various colours; but the experiments of this nature in *Harper's* and *Scribner's* magazines cannot be said to have yet achieved all the success that may be expected. (E. F. S.)

Ilmenau, a town and summer resort of Germany, grand-duchy of Saxe-Weimar, at the north foot of the Thuringian Forest and 30 miles by rail south of Erfurt. The town stands picturesquely amongst wooded hills and is much frequented as a health-resort, and is in German literary history associated with Goethe's *Iphigenie.* It has manufactures of glass and porcelain, toys, gloves, and chemicals, iron and coal mines, and sawmills. Here is a grand-ducal castle, now used as administrative offices. Population (1885), 5483; (1895), 7958; (1900), 10,419.

Iloilo, capital of the province of the same name, situated on the south-east coast of Panay, one of the Philippine Islands. A small tidal river furnishes a well-protected port, suitable for ships of 15 feet draught, while ocean-going vessels can lie off the city in the roadstead between Panay and Guimaras. The town is irregularly built on low ground. Its streets are not paved. There were formerly many good shops and residences, but the town was burned by the Filipino insurgents on the landing of the American troops, 11th February 1899, and has not been fully rebuilt. Iloilo ranks next to Manila in commercial importance among Philippine cities. It was organized as a municipality under Spanish rule. It is a port of entry, and is the main shipping-point for the sugar grown in the Visayan Islands. Cocoanut oil, lime, vinegar, mats, and various articles of palm wood are manufactured. It has a good government house and a fine church. Population, about 12,000.

Imaizumi. See Gifu.

Imbros, a Turkish island in the Ægean, at the southern end of the Thracian Chersonese peninsula. It forms with Samothrace, about 17 miles distant, a caza (or canton) in the sanjak of Lemnos, and province of the Archipelago Isles. The island is the seat of a Greek bishopric. There is communication with the mainland by occasional vessels. The island is of great fertility—wheat, oats, barley, olives, sesame, and valonea being the principal products, in addition to a variety of fruits. The population is about 92,000, nearly all Turks.

Immigration. See Migration.

Impressionism.—The word "Impressionist" has come to have a more general application in England than in France, where it took currency as the nickname of a definite group of painters exhibiting together, and was adopted by themselves during the conflict of opinion which the novelty of their art excited. The word therefore belongs to the class of nicknames or battle-names, like "Romanticist," "Naturalist," "Realist," which preceded it, words into which the acuteness of controversy infuses more of theoretical purport than the work of the artists denoted suggests to later times. The painters included in such a "school" differ so much among themselves, and so little from their predecessors compared with the points of likeness, that we may well see in these recurring effervescences of official and popular distaste rather the shock of individual force in the artist measured against contemporary mediocrity than the disturbance of a new doctrine. The "Olympia" of Manet, hooted at the Salon of 1865 as subversive of all tradition, decency, and beauty, strikes the visitor to the Luxembourg rather as the reversion to a theme of Titian by an artist of ruder vision than as the demonstration of a revolutionary in painting. Later developments of the school do appear to us revolutionary. With this warning in a matter still too near us for final judgment, we may give some account of the Impressionists proper, and then turn to the wider significance sometimes given to the name.

The words *Impressioniste, Impressionisme,* are said to have arisen from a phrase in the preface to Manet's catalogue of his pictures exhibited in 1867 during the Exposition Universelle, from which he was excluded. "It is the effect," he wrote, "of sincerity to give to a painter's works a character that makes them resemble a protest, whereas the painter has only thought of rendering his impression." An alternative origin is a catalogue in which Claude Monet entitled a picture of sunrise at sea "Une Impression." The word was probably much used in the discussions of the group, and was caught up by the critics as characteristic.[1] At the earlier date the only meaning of the word was a claim for individual liberty of subject and treatment. So far as subject went, most, though not all of Manet's pictures were modern and actual of his Paris, for his power lay in the representation of the thing before his eye, and not in fanciful invention. His simplicity in this respect brought him into collision with popular prejudice when, in the "Déjeuner sur l'herbe" (1863), he painted a modern "Fête Champêtre." The actual characters of his painting at this period, so fancifully reproached and praised, may be grouped under two heads. (1) The expression of the object by a few carefully chosen values in flattish patches. Those patches are placed side by side with little attenuation of their sharp collision. This simplification of colour and tone recalls by its broad effects of light and silhouette on the one hand Velasquez, on the other the extreme simplification made by the Japanese for the purposes of colour-printing. Manet, like the other painters of his group, was influenced by these newly-discovered works of art. The image, thus treated, has remarkable hardiness and vigour, and also great decorative breadth. Its vivacity and intensity of aspect is gained by the sacrifice of many minor gradations, and by the judgment with which the leading values have been determined. This matching of values produces, technically, a "solid" painting, without glazing or elaborate transparency in shadows. (2) During this period Manet makes constant progress towards a fair, clear colour. In his early work the patches of blond colour are relieved against black shadows; later these shadows clear up, and in place of an indeterminate brown sauce we find shadows that are colours. A typical picture of this period is the "Musique aux Tuileries," refused by the Salon of 1863. In this we have an actual out-of-doors scene rendered with a frankness and sharp taste of contemporary life surprising to contemporaries, with an elision of detail in the treatment of a crowd and a seizing on the chief colour note and patch that characterize each figure equally surprising, an effort finally to render the total high-pitched gaiety of the spectacle as a banquet of sunlight and colour rather than a collection of separate dramatic groups.

For life of Édouard Manet (1833–1883) see Edmond Bazire. *Manet.* Paris, 1884. An idea of the state of popular feeling may be

[1] Mr H. P. Hain Friswell has pointed out that the word "impression" occurs frequently in Chevreul's book on colour; but it is also current among the critics. See Ruskin's chapter on Turner's composition—"impression on the mind."

gained by reading ZOLA's eloquent defence in *Mon Salon*, which appeared in *L'Événement* (1866) and *Édouard Manet* (1867), both reprinted in *Mes Haines* (Paris, 1880). The same author has embodied many of the impressionist ideals in Claude Lantier, the fictitious hero of *L'Œuvre*. Other writers belonging to Manet's group are THÉODORE DURET, author of *Les Peintres Français en 1867* and *Critique d'avant-garde*, articles and catalogue-prefaces reprinted 1885. See also, for Manet and others, J. K. HUYSMAN'S *L'Art Moderne* (1883) and *Certains*. Summaries of the literature of the whole period will be found in R. MUTHER, *The History of Modern Painting* (tr. London, 1896), not always trustworthy in detail, and Miss R. G. KINGSLEY, *A History of French Art* (1899). For an interesting critical account see W. C. BROWNELL, *French Art* (1892).

The second period, to which the name is sometimes limited, is complicated by the emergence of new figures, and it is difficult as yet, and perhaps will always remain difficult, to say how much of originality belongs to each artist in the group. The main features are an intenser study of illumination, a greater variety of illuminations, and a revolution in *facture* with a view to pressing closer to a high pitch of light. Manet plays his part in this development, but we shall not be wrong probably in giving to Claude Monet (born 1840) the chief rôle as the instinctive artist of the period, and to Camille Pissarro (born 1830) a very large part as a painter curious in theory and experiment. Monet at the early date of 1866 had painted a picture as daring in its naïve brutality of out-of-door illumination as the "Déjeuner sur l'herbe." But this picture has the breadth of patch, solidity, and suavity of paste of Manet's practice. During the siege of Paris (1870–71) Monet and Pissarro were in London, and there the study of Turner's pictures enlarged their ideas of the pitch in lighting and range of effect possible in painting, and also suggested a new handling of colour, by small broken touches in place of the large flowing touches characteristic of Manet. This method of painting occupied much of the discussion of the group that centred round Manet at the Café Guerbois, in the Batignolles quarter (hence called *L'École de Batignolles*). The ideas were: (1) Abolition of conventional brown tonality. But all browns, in the fervour of this revolt, went the way of conventional brown, and all ready-made mixtures like the umbers, ochres, siennas were banished from the palette. Black itself was condemned. (2) The idea of the spectrum, as exhibiting the series of "primary" or "pure" colours, directed the reformed palette. Six colours, besides white, were admitted to represent the chief hues of the spectrum. (3) These colours were laid on the canvas with as little previous mixture on the palette as possible to maintain a maximum of luminosity, and were fused by touch on the canvas as little as possible, for the same reason. Hence the "broken" character of the touch in this painting, and the subordination of delicacies of form and suave continuity of texture to the one aim of glittering light-and-colour notation. Justification of these procedures was sought in occasional features of the practice of Delacroix, of Watteau, of Chardin, in the hatchings of pastel, the stipple of water-colour. With the ferment of theory went a *parti pris* for translating all effects into the upper registers of tone (cf. Ruskin's chapter on Turner's practice in *Modern Painters*), and for emphasizing the colour of shadows at the expense of their tone. The characteristic work of this period is landscape, as the subject of illumination strictly observed and followed through the round of the day and of the seasons. Other pictorial motives were subordinated to this research of effect, and Monet, with a haystack, group of poplars, or church front, has demonstrated the variety of lighting that the day and the season bring to a single scene. Besides Pissarro, Alfred Sisley (1840–1899) is a member of the group, and Manet continues his progress, influenced by the new ideas in pictures like "Le Linge" and "Chez le Père Lathuille."

Edmond Degas (born 1834), a severe and learned draughtsman, is associated with this landscape group by his curiosity in the expression of momentary action and the effects of artificial illumination, and by his experiments in broken colour, more particularly in pastel. The novelty of his matter, taken from unexplored corners of modern life, still more the daring and irony of his observation and points of view, and the strangeness of his composition, strongly influenced by Japanese art, enriched the associations now gathering about the word "impressionist." Another name, that of Auguste Renoir (born 1841), completes the leading figures of the group. Any "school" programme would be strained to breaking-point to admit this painter, unless on the very general grounds of love of bright colour, sunlit places, and independence of vision. He has no science of drawing or of tone, but wins a precarious charm of colour and expression.

The landscape, out-of-doors line, which unites in this period with Manet's line, may be represented by these names: Corot, Jongkind, Boudin, Monet. Monet's real teacher was Eugène Boudin (1824–1898). (See GUSTAVE CAHEN'S *Eugène Boudin*. Paris, 1900.) They, and others of the group, worked together in a painters' colony at Saint Simeon, near Honfleur. It is usual to date the origin of *plein-air* painting, *i.e.*, painting out-of-doors, in an out-of-doors key of tone, from a picture Manet painted in the garden of De Nittis, just before the outbreak of war in 1870. This dates only Manet's change to the lighter key and looser handling. It was Monet who carried the practice to a logical extreme, working on his canvas only during the effect and in its presence. The method of Degas is altogether different, viz., a combination in the studio from innumerable notes and observations. It will be evident from what has been said above that impressionistic painting is an artistic ferment, corresponding to the scientific research into the principles of light and colour, just as earlier movements in painting coincided with the scientific study of perspective and anatomy. CHEVREUL'S famous book, already referred to, *De la loi du contraste simultané des Couleurs* (1838), established certain laws of interaction for colours adjacent to one another. He still, however, referred the sensations of colour to the three impossible "primaries" of Brewster—red, blue, and yellow. The Young-Helmholtz theory affected the palette of the Impressionists, and the work of Ogden Rood, *Colour* (Internat. Scientific Series, 1879–81), published in English, French, and German, furnished the theorists with formulæ measuring the degradation of pitch suffered by pigments in mixture.

The Impressionist group (with the exception of Manet, who still fought for his place in the Salon) exhibited together for the first time as L'Exposition des Impressionistes at Nadar's, Boulevard des Capucines, in 1874. They were then taken up by the dealer Durand-Ruel, and the succeeding exhibitions in 1876, 1877, 1879, 1880, 1881, 1882, and 1886, were held by him in various galleries. The full history of these exhibitions, with the names of the painters, will be found in two works: FÉLIX-FÉNÉON, *Les Impressionistes en 1886* (Paris, 1886), and G. GEFFROY, *La Vie Artistique* (*Histoire de l'Impressionisme*, in vol. for 1894). See also G. LECOMTE, *L'Art Impressioniste d'après la Collection privée de M. Durand-Ruel* (Paris, 1892); DURANTY, *La Peinture Nouvelle* (1876). Besides the names already cited, some others may be added: Madame Berthe Morisot, sister-in-law of Manet; Paul Cézanne, belonging to the Manet-Pissarro group; and later, Gauguin. J. F. Raffaëlli applied a "characteristic" drawing, to use his word, to scenes in the dismal suburbs of Paris; Forain, the satiric draughtsman, was a disciple of Degas, as also Zandomeneghi. Miss Mary Cassatt was his pupil. Caillebotte, who bequeathed the collection of Impressionist paintings now in the Luxembourg, was also an exhibitor; and Boudin, who linked the movement to the earlier schools.

The first exhibitions of the Impressionists in London were in 1882 and 1883, but their fortunes there cannot be pursued in the present article, nor the history of the movement beyond its originators. This excludes notable figures, of which M. Besnard may be chosen as a type.

In Manet's painting, even in the final steps he took towards "*la peinture claire*," there is nothing of the "decomposition of tones" that logically followed from the theories of his followers. He recognized the existence in certain illuminations of the violet shadow, and he adopted in open-air work a looser and more broken touch. The nature of his subjects encouraged such a handling, for the painter who attempts to note from nature the colour

values of an elusive effect must treat form in a summary fashion, still more so when the material is in constant movement like water. Moreover, in the river-side subjects near Paris there was a great deal that was only pictorially tolerable when its tone was subtracted from the details of its form. Monet's painting carries the shorthand of form and broken colour to extremity; the flowing touch of Manet is chopped up into harsher, smaller notes of tone, and the pitch pushed up till all values approach the iridescent end of the register. It was in 1886 that the *doctrinaire* ferment came to a head, and what was supposed to be a scientific method of colour was formulated. This was *pointillisme*, the resolution of the colours of nature back into six bands of the rainbow or spectrum, and their representation on the canvas by *dots* of unmixed pigment. These dots, at a sufficient distance, combine their hues in the eye with the effect of a mixture of coloured *lights*, not of pigments, so that the result is an increase instead of a loss of luminosity. There are several fallacies, however, theoretical and practical, in this "spectral palette" and pointillist method. If we depart from the three primaries of the Helmholtz hypothesis, there is no reason why we should stop at six hues instead of six hundred. But pigments follow the spectrum series so imperfectly that the three primaries, even if we could exactly locate them, limit the palette considerably in its upper range. The sacrifice of black is quite illogical, and the lower ranges suffer accordingly. Moreover, it is doubtful whether many painters have followed the laws of mixture of lights in their dotting, *e.g.*, dotting green and red together to produce yellow. It may be added that dotting with oil pigment is in practice too coarse and inaccurate a method. This innovation of *pointillisme* is generally ascribed to George Seurat (died 1890), whose picture, "La Grande Jatte," was exhibited at the Rue Laffitte in 1886. Pissarro experimented in the new method, but abandoned it, and other names among the *Pointillistes* are Paul Signac, Vincent van Gogh, and van Rysselberghe. The theory opened the way for endless casuistries, and its extravagances died out in the later exhibition of the *Indépendants* or were domesticated in the Salon by painters like M. Henri Martin.

The first modern painter to concern himself scientifically with the reactions of complementary colours appears to have been Delacroix (Leonardo, it should be remembered, left some notes on the subject). It is claimed for Delacroix that as early as 1825 he observed and made use of these reactions, anticipating the complete exposition of Chevreul. He certainly studied the treatise, and his biographers describe a dial-face he constructed for reference. He had quantities of little wafers of each colour, with which he tried colour effects, a curious anticipation of pointillist technique. The pointillists claim him as their grandfather. See PAUL SIGNAC, "D'Eugène Delacroix au Néo-Impressionnisme" (*Revue Blanche*, 1898). For a fuller discussion of the spectral palette see the *Saturday Review*, 2nd, 9th, and 23rd February and 23rd March 1901.

In England the ideas connected with the word Impressionism have been refracted through the circumstances of the British schools. The questions of pitch of light and iridescent colour had already arisen over the work of Turner, of the Pre-Raphaelites, and also of G. F. Watts, but less isolated and narrowed, because the art of none of these limited itself to the pursuit of light. *Pointillisme*, after a fashion, existed in British water-colour practice. But the Pre-Raphaelite school had accustomed the English eye to extreme definition in painting and to elaboration of detail, and it happened that the painting of James M'Neill Whistler (Grosvenor Gallery, 1878) brought the battle-name Impressionism into England and gave it a different colour. Mr Whistler's method of painting is in no way revolutionary, and he prefers to transpose values into a lower key rather than compete with natural pitch, but his vision, like that of Manet under the same influences, Spanish and Japanese, simplifies tone and subordinates detail. These characteristics raised the whole question of *the science and art of aspect in modern painting*, and the field of controversy was extended backwards to Velasquez as the chief master of the moderns. "Impressionism" at first had meant individualism of vision, later the notation of fugitive aspects of light and of movement; now it came to mean breadth in pictorial vision, all the simplifications that arise from the modern analysis of aspect, and especially the effect produced upon the parts of a picture-field by attending to *the impression of the whole.* Ancient painting analyses aspect into three separate acts as form, tone, and colour. All forms are made out with equal clearness by a conventional outline; over this system of outlines a second system of light and shade is passed, and over this again a system of colours. Tone is conceived as a difference of black or white added to the tints, and the colours are the definite local tints of the objects (a blue, a red, a yellow, and so forth). In fully-developed modern painting, instead of an object analysed into sharp outlines covered with a uniform colour darkened or lightened in places, we find an object analysed into a number of surfaces or planes set at different angles. On each of these facets the character of the object and of the illumination, with accidents of reflexion, produces a patch called by modern painters a "value," because it is colour of a particular value or tone. (With each difference of tone, "value" implies a difference of hue also, so that when we speak of a different tone of the same colour we are using the word "same" in a loose or approximate sense.) These planes or facets define themselves one against another with greater or less sharpness. Modern technique follows this modern analysis of vision, and in one act instead of three renders by a "touch" of paint the shape and value of these facets, and instead of imposing a uniform ideal outline at all their junctions, allows these patches to define themselves against one another with variable sharpness.

Blurred definition, then, as it exists in our natural view of things, is admitted into painting; a blurring that may arise from distance, from vapour or smoke, from brilliant light, from obscurity, or simply from the nearness in value of adjacent objects. Similarly, much detail that in primitive art is elaborated is absorbed by rendering the aspect instead of the facts known to make up that aspect. Thus hair and fur, the texture of stuffs, the blades of grass at a little distance, become patches of tone showing only their larger constructive markings. But the blurring of definitions and the elimination of detail that we find in modern pictorial art are not all of this ready-made character. We have so far only the scientific analysis of a field of view. If the painter were a scientific reporter he would have to pursue the systems of planes, with their shapes and values, to infinity. Impressionism is the art that surveys the field and determines which of the shapes and tones are of chief importance to the *interested* eye, enforces these, and sacrifices the rest. Construction, the logic of the object rendered, determines partly this action of the eye, and also decoration, the effects of rhythm in line and harmony in fields of colour. These motives belong to all art, but the specially impressionist motive is the act of *attention* as it affects the aspect of the field. We are familiar, in the ordinary use of the eye, with two features of its structure that limit clearness of vision. There is, first, the spot of clear vision on the retina, outside of which all falls away into blur; there is, secondly, the action of *focus*. As the former limits clear definition to one spot in the field extended vertically and laterally, so focus limits clear definition to one plane in the third dimension, viz.,

depth. If three objects, A, B, and C, stand at different depths before the eye, we can at will fix A, whereupon B and C must fall out of focus, or B, whereupon A and C must be blurred, or C, sacrificing the clearness of A and B. All this apparatus makes it impossible to see everything at once with equal clearness, enables us, and forces us for the uses of real life, to frame and limit our picture, according to the immediate interest of the eye, whatever it may be. The painter instinctively uses these means to arrive at the emphasis and neglect that his choice requires. If he is engaged on a face he will now screw his attention to a part and now relax it, distributing the attention over the whole so as to restore the bigger relations of aspect. Sir Joshua Reynolds describes this process as seeing the whole "with the dilated eye"; the commoner precept of the studios is, "to look with the eyes half closed"; a third way is to throw the whole voluntarily out of focus. In any case the result is that minor planes are swamped in bigger, that smaller patches of colour are swept up into broader, that markings are blurred. The final result of these tentative reviews records, in what is blurred and what is clear, the attention that has been distributed to different parts, and to parts measured against the whole. The Impressionist painter does not allot so much detail to a face in a full-length portrait as to a head alone, nor to twenty figures on a canvas as to one. Again, he indicates by his treatment of planes and definitions whether the main subject of his picture is in the foreground or the distance. He persuades the eye to slip over hosts of near objects so that, as in life, it may hit a distant target, or concentrate its attack on what is near, while the distance falls away into a dim curtain. All those devices by which attention is directed and distributed, and the importance in space of an object established, affect impressionistic composition.

It is an inevitable misunderstanding of painting which plays the game of art so closely up to the real aspects of nature that its aim is that of mere exact copying. Painting like Manet's, accused of being realistic in this sense, sufficiently disproves the accusation when examined. Never did painting show a *parti pris* more pronounced, even more violent. The elisions and assertions by which Manet selects what he finds significant and beautiful in the complete natural image are startling to the stupid realist, and the Impressionist may best be described as the painter who out of the completed contents of vision constructs an image moulded upon his own interest in the thing seen and not on that of any imaginary schoolmaster. Accepting the most complex terms of nature with their special emotions, he uses the same freedom of sacrifice as the man who at the other end of the scale expresses his interest in things by a few scratches of outline. The perpetual enemy of both is the eclectic, who works for possible interests not his own.

Some of the points touched on above will be found amplified in articles by the writer in *The Albemarle* (September 1892), the *Fortnightly Review* (June 1894), and *The Artist* (March–July 1896). An admirable exposition of Impressionism in this sense is R. A. M. STEVENSON's *The Art of Velasquez* (1895). Mr Stevenson was trained in the school of Carolus Duran, where impressionist painting was reduced to a system. Mr Sargent's painting is a brilliant example of the system. (D. S. M.)

Ince-in-Makerfield, a township in the Ince parliamentary division of Lancashire, England, adjoining the borough of Wigan. The Leeds and Liverpool Canal intersects the township. There are large collieries, ironworks, forges, railway-waggon works, and cotton mills here. Walmesley Park, area 26 acres, was opened in 1895. Area, 2320 acres. Population of urban district (1901), 21,270.

Incense.—The article on incense in the earlier volumes of the *Ency. Brit.* (ninth edition) gives a full account of the nature, preparation, and use of incense in ancient as well as modern times, and in different parts of the world, but especially in the East. The object of the present article is to give some information as to the use of incense in the Church of England. Mr Scudamore (*Notitia Eucharistica*, 2nd ed., pp. 141–142) thus describes the method and extent of its employment at the mass prior to the Reformation: "According to the use of Sarum (and Bangor) the priest, after being himself censed by the deacon, censed the altar before the Introit began. The York rubric directed him to do it immediately after the first saying of the Introit, which in England was thrice said. The Hereford missal gives no direction for censing the altar at that time. The middle of the altar was censed, according to Sarum, Bangor, and Hereford, before the reading of the Gospel. According to Sarum and Bangor, the thurible, as well as the lights, attended the Gospel to the lectern. Perhaps the York rubric implies that this was done when it orders (which the others do not) the thurible to be carried round the choir with the Gospel while the Creed was being sung. In the Sarum and Bangor, the priest censed the oblations after offering them; then the space between himself and the altar. He was then, at Sarum, censed by the deacon, and an acolyte censed the choir; at Bangor the *Sinistrum Cornu* of the altar and the relics were censed instead. York and Hereford ordered no censing at the offertory. There is reason to think that, notwithstanding the order for the use of incense at every celebration, it was in practice burnt only on high festivals, and then only in rich churches, down to the period of the Reformation. In most parishes its costliness alone would preclude its daily use, while the want of an assistant minister would be a very common reason for omitting the rite almost everywhere. Incense was not burnt in private masses, so that the clergy were accustomed to celebrations without it, and would naturally forego it on any plausible ground." The ritual of the mass remained unchanged until the death of Henry VIII. (28th January 1547). In March 1548 the *Order of the Communion* was published and commanded to be used by royal proclamation in the name of Edward VI. It was the precursor of the Prayer Book, and supplemented the accustomed Latin service by additions in English to provide for the communion of the people in both kinds. But it was expressly stated in a rubric that the old service of the mass was to proceed without variation of any rite or ceremony until after the priest had received the sacrament, that is, until long after the last of the three occasions for the use of incense explained above. But on Whitsunday 1549 the first Prayer Book of Edward VI. came into use under an Act of Parliament (2 and 3 Ed. VI. ch. 1, the first Act of Uniformity) which required its exclusive use in public worship so as to supersede all other forms of service. Another Act, 3 and 4 Ed. VI. ch. 10, required the old service books to be delivered up to be destroyed. The first Prayer Book does not contain any direction to use or any mention of incense. It has been and still is a keenly controverted question whether incense did or did not continue to be in ceremonial use under the first Prayer Book or during the rest of Edward VI.'s reign. No evidence has hitherto been discovered which justifies us in answering this question in the affirmative. The second Prayer Book of Edward VI. (1552), published under the authority of the second Act of Uniformity (5 and 6 Ed. VI. ch. 1), contains no reference to incense. Edward VI. died on the 6th July 1553. Queen Mary by statute (1 Mary, sess. 2, ch. 2) abolished the Prayer Book, repealed the Acts of Uniformity, and restored "divine service and administration of sacraments as were most commonly used in

England in the last year of Henry VIII." The ceremonial use of incense thus became again an undoubted part of the communion service in the Church of England. A proclamation issued (6th December 1553) directed the churchwardens to obtain the proper ornaments for the churches; and the bishops (at any rate Bishop Bonnor, see *Visitation Articles 1554*, Cardwell's *Doc. Ann.* vol. i. pp. 149–153) in their visitations inquired whether censers had been furnished for use. Mary died 17th November 1558. On 24th June 1559 the second Prayer Book of Edward VI. (with a few alterations having no reference to incense) was again established, under the authority of the third Act of Uniformity (1 Eliz. ch. 2), as the exclusive service book for public service. There is no evidence of the ceremonial use of incense under Elizabeth's Prayer Book, or under the present Prayer Book of 1662 (established by the fourth Act of Uniformity, 13 and 14 Charles II. ch. 4) until the middle of the 19th century; and there is no doubt that as a ceremony of divine worship, whether at the Holy Communion or at other services, it was entirely disused. There are, however, a good many instances recorded of what has been called a fumigatory use of frankincense in churches, by which it was sought to purify the air, in times of public sickness, or to dispel the foulness caused by large congregations, or poisonous gases arising from ill-constructed vaults under the church floor. It seems also to have been used for the purpose of creating an agreeable perfume on great occasions, *e.g.*, the great ecclesiastical feasts. But this use of incense must be carefully distinguished from its ceremonial use. It was utilitarian and not symbolical, and from the nature of the purpose in view must have taken place before, rather than during, service. Of the same character is the use of incense carried in a perfuming pan before the sovereign at his coronation in the procession from Westminster Hall to the Abbey. This observance was maintained from James II.'s coronation to that of George III. In the general revival of church ceremonial which accompanied and followed the Oxford Movement incense was not forgotten, and its ceremonial use in the Pre-Reformation method has been adopted in a few extreme churches since 1850. Its use has been condemned as an illegal ceremony by the ecclesiastical courts. In 1868 Sir Robert Phillimore (Dean of the Arches) pronounced the ceremonial use of incense to be illegal in the suit of *Martin* v. *Mackonochie* (2 A. and E. L.R. 116). The case was carried to the Privy Council on appeal, but there was no appeal on the question of incense. Again, in 1870, the ceremonial use of incense was condemned by Sir Robert Phillimore in the suit of *Sumner* v. *Wix* (3 A. and E. L.R. 58).

Notwithstanding these decisions, it was insisted by those who defended the revival of the ceremonial use of incense that it was a legal custom of the Church of England. The question was once more elaborately argued in May 1899 before an informal tribunal consisting of the archbishop of Canterbury (Dr Temple) and the archbishop of York (Dr Maclagan), at Lambeth Palace. On 31st July 1899 the archbishops decided that the liturgical use of incense was illegal. The Lambeth "opinion," as it was called, failed to convince the clergy against whom it was directed any better than the judgments of the ecclesiastical courts, but at first a considerable degree of obedience to the archbishops' view was shown. Various expedients were adopted, as, *e.g.*, the use of incense just before the beginning of service, by which it was sought to retain incense without infringing the law as laid down by the archbishops. There remained, nevertheless, a tendency on the part of the clergy who used incense, or desired to do so, to revert to the position they occupied before the Lambeth hearing—that is, to insist on the ceremonial use of incense as a part of the Catholic practice of the Church of England which it is the duty of the clergy to maintain, notwithstanding the decisions of ecclesiastical judges or the opinions of archbishops to the contrary. (L. T. D.)

Income Tax.—*United Kingdom.*—An income tax was originally imposed by Mr Pitt in 1798, but it did not assume its present form until 1803. It lapsed in 1816, and was revived by Sir R. Peel's Government in 1842. It had always been regarded as a temporary measure, and is still renewed annually; but it has now become so important a feature of the fiscal system that there does not appear to be any prospect of its being again abandoned. Speaking broadly, it is a tax levied on all incomes derived from sources within the United Kingdom, or received by residents in the United Kingdom from other sources. But incomes under £160 are exempt; and an abatement is allowed of £160 on those between £160 and £400; of £150 on those between £400 and £500; of £120 on those between £500 and £600; and of £70 on those between £600 and £700. An abatement is also allowed on account of any premiums paid for life assurance, provided they do not exceed one-sixth of the total income. The existing limit of total exemption was fixed in 1894, when it was raised from £150; and the scale of abatements was last revised in 1898 by admitting incomes between £500 and £700. The rate of charge has been as high as 16d. (in 1855–57), and as low as 2d. (in 1874–76). Each penny of the tax was estimated to produce in 1898–99 a revenue of £2,248,000. The tax is assessed under five different schedules, known as A, B, C, D, and E. Under schedule A are charged the incomes derived from landed property, including houses, the annual value or rent being the basis of the assessment. A reduction is allowed from this value of one-eighth in the case of land and one-sixth in the case of houses. The occupier is liable for the tax, but is entitled, if not himself the owner, to deduct a proportionate part of the tax on paying his rent. Under schedule B are charged the profits arising from the occupation of land. The amount of such profits is assumed to be one-third of the annual value of the land as fixed for the purposes of schedule A; but the farmer may, if he chooses, be assessed under schedule D on his actual profits. Schedule C includes income derived from interest, &c., payable out of the public funds of this or any other country. Schedule D, which is the most important branch of the income tax and the most difficult to assess, includes profits arising from trade, from professional or other employment, and from foreign property. The assessment is in most cases made on an average of the receipts for three years. Schedule E covers the salaries and pensions of persons in the employment of the state or of public bodies, and of the higher officials of public companies, &c. The assessment and collection of the tax under schedules A, B, and D are in the hands of local authorities known as the General or District Commissioners of Taxes. They are appointed by the Land Tax Commissioners out of their own body, and, as regards assessment, are not in any way controlled by the executive Government. They appoint a clerk, who is their principal officer and legal adviser, assessors for each parish, and collectors. There is an appeal from their decisions to the High Court of Justice on points of law, but not on questions of fact. Assessments under schedules A and B are usually made every five years, and under schedule D every year. The interests of the revenue are looked after by officers of the Board of Inland Revenue, styled Surveyors of Taxes, who are stationed in different parts of the country. They are in constant communication with the Board and with the

public on all matters relating to the assessment and collection of the tax; they attend the meetings of the local commissioners, examine the assessments and the taxpayers' returns, and watch the progress of the collection. There are also three officers, known as Special Commissioners, who are appointed by the Crown and receive fixed salaries from public funds. For the purpose of schedule D, any taxpayer may elect to be assessed by them instead of by the local commissioners; and those who object to their affairs being disclosed to persons in their own neighbourhood may thus have their assessments made without any risk of publicity. The Special Commissioners also assess the profits of railway companies under schedule D, and profits arising from foreign or colonial sources under schedules C and D. The greater part of the incomes under schedule E is assessed by the commissioners for public offices, appointed by the several departments of the Government.

For further information reference should be made to DOWELL's *Income Tax Laws*, and the Annual Reports of the Commissioners of Inland Revenue, especially those issued in 1870 and 1885.

(G. H. M.)

United States.—One of the means adopted by the Federal Government for meeting its expenses during the Civil War was the levying of an income tax. By the Act of Congress of 5th August 1861 a tax of 3 per cent. was imposed on all incomes, with an exemption of $800, and was made payable on or before the 30th of June 1862. No tax, however, was assessed under the law. In March 1862 a new Income Tax Bill was introduced into the House of Representatives. This Act, which was signed 1st July 1862, imposed a tax of 3 per cent. on all incomes not over $10,000, and 5 per cent. on all incomes above that sum, with an exemption of $600. It was also provided that dividends of banks, insurance companies, and railways should be assessed directly; but the bondholder was allowed to deduct the dividend so assessed from his taxable income. In the case of Government salaries, the tax was deducted before the salaries were paid. The income tax was first levied in 1863. The rate was changed by Act of Congress in 1865, 1867, and 1870; and a joint resolution in 1864 imposed a special additional tax of 5 per cent. for that year. The tax was finally abolished in 1871. The total amount produced by the tax from the beginning was $376,150,209. The constitutionality of the Act was subsequently brought into question, but was upheld by a unanimous decision of the Supreme Court in 1880, which held that the tax was not a direct tax but an excise tax, and that Congress had a right to impose it so long as it was made uniform throughout the United States. On 27th August 1894 an Income Tax Act was passed as part of the Wilson Bill. By this Act it was provided that a tax of 2 per cent. on all incomes should be levied from 1st January 1895 to 1st January 1900, with an exemption of $4000. The legality of the tax was assailed chiefly on the ground that it was a direct tax, and not apportioned among the several states in proportion to their population. On 20th May 1895 the Supreme Court, by a vote of five to four, declared the tax to be unconstitutional.

Independence, capital of Jackson county, Missouri, U.S.A., three miles south of the Missouri on the high prairie, at an altitude of 950 feet. It is built on an undulating site, with a regular plan, and is on the Chicago and Alton and the Missouri Pacific Railways, besides being connected with Kansas City, 14 miles distant, by street railway. It is one of the oldest cities in Missouri, having been founded on the frontier in 1827. For many years thereafter it was the outfitting and starting point for emigrant and exploring parties for the Far West and the Pacific coast. Population (1880), 3146; (1890), 6380; (1900), 6974.

INDIA.

GEOGRAPHY AND STATISTICS.

INDIA, the great country of Asia under British rule or control, from which King Edward VII. takes the title of Emperor, in succession to the first British Empress of India, Queen Victoria, is a peninsula with a length extending from the 8th to the 37th degree of north latitude, or about 2000 miles. Its greatest breadth is nearly the same distance. To this the British have added the country of Burma, extending along the eastern side of the Bay of Bengal, and stretching inland to the frontiers of China, French Laos, and Siam. Besides the Andaman, Nicobar, and Laccadive Islands, the outlying station of Aden at the mouth of the Red Sea is politically included within the Indian Empire; while dots on the shore of the peninsula itself, representing old Portuguese and French settlements, break at intervals the continuous line of British territory.

Politically, India is divided into some thirteen provinces of varying size under direct British administration, and a number of native States, estimated at more than 200, which exercise more or less of the attributes of sovereignty under British control. According to Act of Parliament (52 and 53 Vict. c. 63, sec. 18, subsecs. 4 and 5), "British India" is interpreted to mean "all territories and places within His Majesty's dominions which are for the time being governed by His Majesty through the governor-general of India or through any other governor or officer subordinate to" him; and "India" is interpreted to mean "British India together with any territories of any native prince or chief under the suzerainty of His Majesty exercised through the governor-general of India, or through any other governor or officer subordinate to" him. Native States occupy about 38 per cent. of the total area, and contain about 23 per cent. of the total population. They vary in size from Haidarabad or the Nizam's Dominions (with an area of 83,000 square miles and a population of 11 millions) to a share of a petty village in Kathiawar. The one feature common to all alike is that ordinary British administration is excluded. In Anglo-Indian phraseology, all relations with them are "political" (see below, *Native States*). Except where otherwise mentioned, as in the section on population, the remainder of this article will deal only with British India.

Population.—The preliminary results of the census of 1901 will be given farther on. For all details of population recourse has had to be made to the census of 1891. In order to obtain the aggregate population of all India, it is necessary to include certain regions to which the census of 1891 did not extend. For the two independent States of Nepal and Bhutan in the Himalaya no trustworthy estimates are available. In the frontier State of Manipur (subordinate to Assam) the records of the census were destroyed in the disturbances of April 1891. In the State of Sikkim (subordinate to Bengal), in British Baluchistan (excluding Quetta), in some of the Shan States and other frontier tracts of Burma, and also in the hill tracts of Rajputana (mainly occupied by Bhils), only an informal registration was made, so far as possible synchronously with the census. In the Andaman Islands (outside the convict settlement of Port Blair), in the trans-Salween Shan States, and in the Kakhyen hill country lying between Burma and Assam, no enumeration was attempted. In the French settlements a census was taken simultaneously with that of British India. For the Portuguese possessions the returns are those of the census of 1887. The following table adds all these excluded items:—

Tract.	Number of Persons.
Sikkim (registered)	30,458
Manipur (estimated)	250,000
British Baluchistan (registered)	145,417
Cis-Salween Shan States (registered)	372,969
Burma Frontier Tracts	116,493
Rajputana Hill Tracts (registered)	204,241
French Settlements	282,923
Portuguese Possessions	561,384
Included in the Census	287,223,431
Aggregate	289,187,316

The census of 1891, which was taken over an area of 1,560,160 square miles, returned a total population of 287,223,431, the average density being 184 persons per square mile. The census of 1881 was taken over a somewhat smaller area, omitting Upper Burma and the State of Kashmir. For the same area, the population increased in ten years by no less than 27,821,420, or at the rate of 10·96 per cent. In British territory alone the increase was 19,294,509, or at the rate of 9·7 per cent.; in native States the increase was 8,526,911, or at the rate of 15·5 per cent. Some portion of this increase, especially in native States, is due to improved enumeration, as is evidenced by the higher rate of increase among females (11·16, compared with 10·77 per cent. for males). Some portion, again, is due to recovery from the famine of 1876–78, shown by the percentages of increase in Mysore (18·09), Madras (15·58), and Bombay (13·71), where that famine was most severe. Apart from these two considerations, it is noteworthy that the highest rates of increase were almost always found in the most thinly peopled tracts, such as Lower Burma, Sind, and the hills of Northern and Central India. The only considerable area that showed an actual decrease (1·4 per cent.) was the water-logged Doab of the North-Western Provinces; but in Northern Bengal the rate of increase fell to 4·7 per cent., and in Southern Behar to 2·8 per cent.

The accompanying table shows the area and population, distributed between British provinces and native States, according to the census of 1891.

The *linguistic* information ascertained by the census of 1891 did not extend to Rajputana, Central India, and Kashmir. It was confined to a total population of 262,047,440. Of these, 195,463,807, or 47·6 per cent., spoke languages of the Aryo-Indic group, of which the chief representatives are Hindi, Bengali, Marathi, Punjabi, Gujarati, and Uriya; 52,964,620, or 20·2 per cent., spoke languages of the Dravidian group, of which the chief representatives are Telugu, Tamil, Kanarese, and Malayalam; 7,293,928, or 2·8 per cent., spoke languages of the Tibeto-Burman group; 2,959,006, or 1·1 per cent., spoke languages of the Kolarian group, of which Sonthali is the chief representative; and 1,329,428, or ·5 per cent., spoke languages of the Aryo-Iranic group, chiefly represented by Pashtu or Pakhtu, the vernacular of the Afghans.

For the *ethnology*, the best evidence is derived from the classification of the census of 1891 according to caste or occupation. The largest group was that of respectable cultivators, who numbered 47,927,361, or 16·7 per cent. of the total. Next came the village menials (including leather-workers), who numbered 30,795,703, or 10·7 per cent. Military Hindus (including Rajputs, Jats, Marathas, and Gujars) numbered 29,393,870, or 10·2 per cent.; artisans, 28,882,551, or 10·1 per cent; cowherds and shepherds, 16,721,494, or 5·8 per cent.; forest tribes, 15,806,914, or 5·5 per cent.; priests (mostly Brahmans), 15,467,752, or 5·4 per cent.; and traders, 12,270,973, or 4·3 per cent.

Sex.—The classification of the census of 1891 according to sex showed that the female population was in defect by more than six millions. In other words, there were 958 females to every 1000 males. It was only in Upper Burma, Madras, and Bengal that the females were in excess. In the North-Western Provinces the deficiency fell to 923, and in the Punjab to 854 per 1000 males. After a careful examination of all the circumstances, the Census Commissioner (Mr J. A. Baines, C.S.I.) came to the following conclusions:—"In most parts of India proper there is a tendency, in a greater or less degree, to omit from the census record girls of from nine to fifteen, and wives of from fifteen to twenty or thereabouts; but in every part of the country except the north girls below five are returned as more numerous

Area and Population of British India and Native States, 1891.

than boys of that age. After that period, apart from wilful or ignorant omission, there is probably a real deficiency in the number of females, extending to about the twentieth year, and due to neglect, premature cohabitation, and unskilful midwifery. At a later period, hard work, as well as the results of the above influences, and among some classes excessive fecundity, tell on the female constitution, producing greater relative mortality than prevails in the other sex."

Religion.—The following table distributes the population in 1891 according to religion:—

Population classified according to Religion.

	Number.	Per cent.	Tracts where proportionately most numerous.
Hindus	207,731,727	72·34	The South and the mid-valley of the Ganges.
Mahommedans	57,321,164	19·96	Sind, Punjab, Eastern Bengal, and Kashmir.
Aborigines	9,280,467	3·23	Central Provinces, Central India, Bengal, and Assam.
Buddhists	7,131,361	2·48	Burma.
Christians	2,284,380	·79	The South, Burma, and Bengal.
Sikhs	1,907,833	·66	Punjab.
Jains	1,416,638	·49	Rajputana and Bombay.
Parsis	89,904	·03	Bombay.
Jews	17,194	·01	Bombay.
Others	42,763	·01	Kashmir, Madras, and Bengal.

The only term that requires explanation is "aborigines," which is here used as equivalent to "animistic," for all such wild tribes as are not locally acknowledged to have become either Hindus, Mussulmans, Buddhists, or Christians. Classified according to race, the aboriginal tribes numbered about 15,922,000.

The following table distributes the Christian population in 1891 according to sect:—

Table showing Distribution of Christian Sects.

	Number.	Per cent.
Church of England	295,016	12·9
Presbyterian	40,407	1·8
Baptist	191,746	8·4
Other Protestant	140,592	6·1
Roman Catholic	1,315,263	57·6
Syrian	200,467	8·8
Others	100,889	4·4

Classified according to another principle, Europeans numbered 168,000, of whom just half are estimated to be soldiers or the families of soldiers; Eurasians numbered 79,790; and native converts 2,036,590, of whom no less than 61 per cent. were Roman Catholics, and 10 per cent. Syrians of the Jacobite rite. In the native States of Madras, on the Malabar coast, Christians form one-fifth of the total population. Their number is also considerable among the Karens of Burma and the aboriginal tribes of Chota Nagpur.

Towns.—There is little tendency for the people to crowd into towns. According to the census of 1891, the urban population numbered 27,251,176, or 9·5 per cent. of the total, leaving 90·5 per cent. for the rural population. Again, as compared with 1881, the rate of increase in the urban population was only 9·4 per cent., compared with 10·9 per cent. for the general population. It must further be remarked that this urban population was contributed by 2035 towns, of which 505 had less than 5000 inhabitants. The number of towns with more than 20,000 was only 225. The accompanying table gives a list of all the towns in 1891 with more than 100,000 inhabitants. Bombay stands at the top, as the second most populous city in the British Empire. But if all the suburbs were added to Calcutta, and also Howrah on the opposite bank of the river, the total population of the metropolis on the Hooghly would be raised to more than a million. Haidarabad, Jaipur, Srinagar, Baroda, and Gwalior owe their importance entirely to the courts of large native States. Lucknow, Delhi, Mandalay, Agra, and Poona were formerly capitals. Rangoon and Karachi, as prosperous seaports, show the highest rate of increase. Cawnpore, Bangalore, and Ahmadabad are thriving centres of trade and manufacture.

List of Towns with a Population of more than 100,000.

Census of 1901.—The census of 1901, the third general census of India, was taken on the night of 1st March, and the preliminary returns were published on 14th March. They are given in the table on the following page, which shows the population, male and female, according to British provinces and native States, with the variations as compared with the census of 1891. The operations of the census of 1901 extended for the first time to the Shan States and hill tracts of Burma, to the border States of Manipur and Sikkim, to the troops stationed on the Afghan frontier, to almost the whole of Baluchistan, and to the Andaman and Nicobar islanders. The total population amounted to 294,266,701, compared with 287,223,431 in 1891, showing an increase of 7,043,270, or 2·42 per cent. But if the area not enumerated before be excluded, the increase is reduced to 4,283,069, or 1·49 per cent. In British territory alone the rate of increase is 4·44 per cent., against which there falls to be set off a decrease at the rate of 4·34 per cent. in native States. Some evidence of the general accuracy of the enumeration may be drawn from the fact that females have apparently increased more than males, the proportion of females to every 1000 males having risen from 958 to 963.

An examination of the details clearly reveals the effects of recent famine. In the native States of Rajputana, Central India, Bombay, and Baroda the aggregate decrease is more than 5½ millions, compared with an aggregate increase of more than 4 millions in the preceding decade. The Central Provinces show a decrease of nearly one million, compared with an increase of almost an identical amount. In each of the five Gujarat districts of Bombay there is a decrease, amounting altogether to nearly 400,000. Even where famine was not severe, the rate of increase generally diminished. In Bengal it

dropped from 6·9 to 4·7 per cent., most of the densely populated districts of Behar showing an actual decrease. In the North-Western Provinces it dropped from 6·3 to 1·6 per cent.; in the Punjab, despite the extension of canal irrigation, from 10·7 to 7·6 per cent.; and in Madras from 15·6 to 7·2 per cent. Only in Assam was the rate of increase higher than in the preceding decade; and here the whole of the increase may be attributed to the immigration of labourers on the tea gardens. Burma, which stands outside the Indian peninsula and has enjoyed unbroken prosperity, shows an exceptional increase of 18·7 per cent.

The preliminary returns of the census of 1901 show some variations in the size of the large towns. Calcutta now stands easily first, with a population of 843,487, having increased by about 24 per cent. in each of the two preceding decades. If the suburbs and Howrah be added, the total is raised to 1,279,511. In Bombay, on the other hand, the population decreased to 770,843, or by 6 per cent., owing to the continued effects of plague. Madras shows a steady rate of increase, to 509,397. Rangoon, the capital and chief port of Burma, rose from the eleventh to the sixth place in the list, with 232,326 inhabitants, being an increase of 29 per cent. The results of plague again appear at Karachi and Poona, which both suffered severely. Karachi, with 115,407 inhabitants, shows an increase of only 9 per cent., compared with an increase of 43 per cent. in the preceding decade. At Poona the population fell to 111,385, or by as much as 31 per cent. The same cause reduced the population of Bangalore to 159,030, or by 12 per cent. Two cities of the Madras presidency, Madura and Trichinopoly, rise to the class with more than 100,000 inhabitants.

Agriculture.—Agriculture forms the main occupation of the inhabitants. According to the census of 1891, the number of persons employed in agriculture or in connexion with cattle was 175,381,239, being 61 per cent. of the total population. If we add, as we fairly may, most of those returned as general labourers, the proportion would rise to two-thirds. Of these, 149,931,159 were landholders or tenants, 18,673,206 agricultural labourers, and 3,645,849 employed with cattle. Agricultural statistics are now collected by a government department for every British province, though for Bengal the figures must be regarded as only approximate estimates. The two following tables give the returns according to provinces for 1897–98, which may be taken as an average year. The first of these tables shows that, out of the total area for which returns exist (excluding tributary States and mountainous or desert regions), forests cover 12 per cent., and an additional 25 per cent. is not available for cultivation. Of the remainder, 36 per cent. actually yielded crops in 1897–98, while 7 per cent. was current fallow and 20 per cent. cultivable waste. The second table shows the area under each of the principal crops. Of the total cultivated area in 1897–98, no less than 93 per cent. was devoted to food-crops of various kinds, including pulse. Rice alone covers 36 per cent., and wheat 10 per cent. But these two crops are very unevenly distributed. In Lower Burma hardly anything else is grown but rice; and rice is also the predominant crop in Eastern Bengal and Orissa, in the adjoining valleys of Assam, in the deltas of the Madras rivers, along the sea-coast under the Western Ghats, and among the hills of Chhattisgarh. Wheat, on the other hand, is grown mainly in the plains of the Punjab and the North-Western Provinces, in the valley of the Narbada, and generally throughout the Bombay presidency. Except in the rice tracts, the staple food of the people is derived from millet and other inferior grains, chiefly *jowar* and *bajra* in the

Industries and trade.

north, and *ragi* in the south. A little sugar-cane is grown everywhere, but it forms an important crop only in Northern India, from Bengal to the Punjab. Tobacco, also, is grown everywhere in garden plots, but chiefly in Bengal, Upper Burma, Madras, and Bombay. Oil-seeds of different kinds (chiefly linseed, mustard, and gingelly) are grown everywhere for local consumption, and for export in Bengal, the Central Provinces, Bombay, Madras, and the Punjab. Cotton also is widely distributed, the chief exports being derived from Berar, Bombay, the Central Provinces, and Madras. Jute is confined to Eastern Bengal, with a slight extension into the valleys of Assam.

The following table shows the area under irrigation, omitting Bengal and Assam. In the latter province there is no irrigation whatever, and in the former it is practised to an insignificant extent, as is also the case in Lower Burma. For the rest of British India, just one-fifth of the total area under crops was irrigated in 1897–98, the proportion in the large provinces ranging from 37 per cent. in the Punjab to 14 per cent. in Bombay. Excluding Sind, where more than three-fourths of the cultivated area requires irrigation, the proportion for Bombay would fall to 4 per cent., being little higher than in the Central Provinces. It was in the unirrigated tracts of Gujarat, Berar, and the Central Provinces that the famine of 1900 was felt with greatest severity. Government canals have been most widely extended in the Punjab, Sind, the North-Western Provinces, and Madras. Private canals are found chiefly in

Table of Certain Areas under Irrigation, 1897–98.

the Punjab, Upper Burma, and Sind. Irrigation from tanks is practised chiefly in Madras and the Central Provinces, irrigation from wells in the Punjab, the North-Western Provinces and Oudh, Madras, and Bombay. The principal crop grown on irrigated land is wheat; and altogether more than 90 per cent. of the total irrigated area in 1897–98 was devoted to food-crops (see also IRRIGATION).

Tea, Coffee, Indigo.—The principal agricultural products raised under European supervision and with the help of European capital are tea, coffee, and indigo. Tea is chiefly grown in the extreme north-east—in the two valleys of Assam and in the neighbourhood of Darjiling (Bengal). The following table shows the area under tea (both mature and immature plants) for the seven years 1893–99 :—

Tract.	1893.	1894.	1895.	1896.	1897.	1898.	1899.

Total	397,539	399,775	415,717	433,280	493,710	501,680	516,732

In 1899 the total production was 186,525,000 ℔, of which more than two-thirds came from Assam and nearly one-fourth from Bengal. The total number of persons employed was 655,000, including 96,000 temporary labourers.

The cultivation of coffee is practically confined to the extreme south. It is subject to greater vicissitudes than that of tea, and is generally a less prosperous industry than it was in 1880. A considerable proportion is grown by natives, especially in Mysore. The following table shows the area under coffee for the seven years 1893–99 :—

Tract.	1893.	1894.	1895.	1896.	1897.	1898.	1899.
	Acres.	Acres.	Acres.	Acres.	Acres.	Acres.	Acres
Coorg	63,783	71,181	73,828	84,820	86,155	82,575	72,296
Madras	62,245	64,512	63,953	56,851	55,895	63,983	66,473
Mysore	132,520	136,032	138,670	141,528	125,876	128,079	128,010
Travancore and Cochin	6,244	6,589	7,033	5,748	7,840	6,384	7,069
Burma, Assam, &c.	198	248	267	319	308	548	450
Total	264,990	278,562	283,751	289,266	276,074	281,569	274,298

Owing to poor crops and low prices, the total export of coffee was only 225,000 cwts. in 1897–98, as compared with 312,000 cwts. in 1891–92. In 1899–1900 it rose again to 281,000 cwts. The total number of persons employed was returned as 110,000, of whom 83,000 were temporary labourers.

The cultivation of indigo is even more fluctuating than that of coffee. The normal area under indigo is 1,400,000 acres, of which more than one-third is in Bengal, about one-fourth in the North-Western Provinces, another fourth in Madras, and most of the remainder in the Punjab. European capital is almost confined to Behar in Bengal and the neighbouring districts of the north-west. In 1900 the total area under indigo was only 964,000 acres. The total exports of indigo ranged from 187,000 cwts. in 1895–96 to 111,000 cwts. in 1899–1900.

Textiles.—Next after agriculture, the spinning and weaving of cotton at steam mills is the most important industry in India, being chiefly concentrated in Bombay. The following table gives the principal statistics of this industry for the five years named :—

Year.	Mills.	Looms.	Spindles.	Persons Employed.
1882–1883	62	15,116	1,654,108	53,624
1887–1888	97	18,840	2,375,739	80,515
1892–1893	130	26,317	3,378,303	120,898
1897–1898	163	36,946	4,210,756	148,435
1899–1900	186	38,420	4,728,000	163,200

The total capital invested was more than Rx.15,000,000, almost entirely provided by joint-stock companies. The total consumption of raw cotton was estimated at 464,000 bales of 400 ℔ each; being more than half of the normal production. For 1899–1900 the total output of yarn was reported as 501,294,000 ℔, of which 62,071,000 ℔ (or 13 per cent.) was of counts above No. 20; but the production of these finer counts from imported cotton is steadily increasing. The total out-turn of woven goods was reported as 95,320,000 ℔. Of the total number of persons employed in 1897–98, 95,962 were adult males, 26,114 women, 15,789 young persons, and 10,570 children. Bombay possessed 70 per cent. of the mills and produced 83 per cent. of the woven goods. There were fourteen mills situated in native States and in French territory.

The spinning and weaving of jute, like the cultivation of the fibre, is practically confined to Bengal, the steam mills being concentrated round Calcutta. The following table gives the chief statistics of this industry for the five years named :—

Year.	Mills.	Looms.	Spindles.	Persons Employed.
1882–1883	20	5,633	95,737	42,797
1887–1888	25	7,389	146,302	56,007
1892–1893	27	8,976	181,172	67,291
1897–1898	35	13,615	274,907	95,934
1899–1900	33	14,021	293,218	101,630

The total capital invested exceeds Rx.5,000,000, almost entirely provided by joint-stock companies. No returns of the out-turn are available, but the total quantity of raw jute worked up in the Indian mills is about 7,000,000 cwts., compared with an export of about double that quantity. Of the total number of persons employed in 1897–98, 62,247 were adult males, 17,090 women, 5740 young persons, and 10,853 children, showing a much larger proportion of children than in cotton mills.

In 1898 there were four mills for spinning and weaving wool, with 588 looms and 21,444 spindles, employing 2904 persons. The capital invested was Rx.445,000, and the output for 1898 was nearly 3,000,000 ℔, valued at Rx.307,247, chiefly blankets and greatcoats for the army and police, made from the short-stapled Indian wool.

Other Manufactures.—There were in 1898 nine paper mills, employing 4187 persons. The capital invested was Rx.627,200, and the out-turn was 42,000,000 ℔, valued at Rx.610,000. The materials used are chiefly rags, grasses, jute cuttings, &c. Most of the paper used in Government offices is now obtained from these mills. The number of breweries, mostly at hill stations in the Himalaya, is 27, with an out-turn of about 6,000,000 gallons, half of which is purchased by the Commissariat Department. The local production of beer is about twice as large as the import. One boot factory at Cawnpore turned out no less than 735,000 pairs of boots for military purposes during the two years 1899 and 1900.

Other large industries are the rice mills and timber mills of Burma, the factories for ginning and pressing cotton throughout Western India, a few sugar refineries, the Barrakur iron works in Bengal, and the pottery works at Raniganj (also in Bengal).

In 1899 the total number of factories under inspection was 1110, employing 452,796 persons, of whom 65,303 were women, 27,459 young persons, and 27,459 children. During the year the number of accidents reported was 2603, of which 77 were fatal. The convictions for breaches of the Factory Act numbered only 3. In 1899–1900 the total number of joint-stock companies registered was 1340, with an aggregate paid-up capital of £23,625,850.

Coal.—The coal industry is progressing rapidly, especially in Bengal. The following table gives the output of all the coal mines in India for the seven years 1893–99 :—

Tract.	1893.	1894.	1895.	1896.	1897.	1898.	1899.
	Tons.	Tons.	Tons.	Tons.	Tons.	Tons.	Tons.
Bengal	1,915,000	2,036,000	2,718,000	3,038,000	3,142,497	3,622,090	3,883,000
Nizam's Dominions. .	157,000	241,000	293,000	263,000	365,550	394,622	401,000
Assam	164,000	169,000	173,000	177,000	185,533	200,329	226,000
Central Provinces . .	135,000	141,000	123,000	142,000	131,629	149,709	157,000
Central India (Rewa) .	94,000	133,000	118,000	115,000	124,778	134,726	164,000
Punjab	77,000	66,000	72,000	79,000	92,792	85,862	82,000
Baluchistan . . .	20,000	22,000	23,000	11,000	8,876	10,667	12,000
Upper Burma . . .	...	12,000	17,000	23,000	11,472	6,975	8,000
Total . . .	2,562,000	2,820,000	3,537,000	3,848,000	4,063,127	4,604,980	4,933,000

In 1898 the total output was valued at Rx.1,430,467 ; the average value being Rs.3·11 per ton, as compared with Rs.19·44 per ton for imported coal. The total number of persons employed in coal-mining in 1899 was 72,000, of whom 51,000 were adult males. Nearly one-third of the total output was consumed by the railways, which now use an insignificant proportion of imported coal (less than 3 per cent. in 1898). Bengal alone produced nearly four-fifths of the total, exporting by sea to Bombay, Madras, Burma, Ceylon, and the Straits, as well as inland by rail and river. A revised Act for the regulation of coal mines was passed by the Viceroy's Council in March 1901.

Gold.—Gold is known to exist in various parts, and gold-washing is practised in many of the hill streams ; but the extraction of the precious metal by quartz-crushing has been successfully pursued only in the Kolar gold-field of Mysore. Here there are two companies, the Mysore and the Champion, which produce each about 150,000 oz. in the year ; while the total production steadily rose from 163,000 oz. in 1892 to 510,000 oz. in 1900. A royalty of 5 per cent. is paid to the Mysore State.

Petroleum.—The most important source of petroleum is in Upper Burma, where the output increased from 8,000,000 gallons in 1893 to 37,000,000 gallons in 1900. The petroleum is refined at Rangoon. Petroleum is also produced in the extreme north-east of Assam, in the neighbourhood of a coal-field. The output here rose from 42,000 gallons in 1893 to 753,000 gallons in 1900. In addition, there are petroleum wells on the north-west frontier; but those in British Baluchistan, which in one year yielded 70,000 gallons, have not been worked since 1894, and the total output in the Punjab is only 2000 gallons a year. Compared with these figures, the total import of mineral oils amounted to more than 80,000,000 gallons.

Salt.—Salt is produced by evaporation almost everywhere along the sea-coast, and at certain inland lakes, of which the Sambhar Lake in Rajputana is the most important. It is also obtained by mining at two places in the Punjab. Its manufacture is a government monopoly. The annual production amounts to about 1,000,000 tons, compared with an importation of about 400,000 tons.

For the statistics concerning railways, see the section *History* below. The following table shows the general course of the foreign sea-borne trade since 1870. To avoid accidental fluctuations, quinquennial averages have been taken. First are given the value of the imports and exports of merchandise only, and the excess value of the exports of merchandise ; then the net imports of treasure, the exports having been deducted ; and finally, the excess value of the exports of both merchandise and treasure which may be regarded as the payment by India to foreign countries for interest on capital invested and for services rendered.

Foreign trade.

Table of Foreign Trade (Sea-borne) since 1870.

Five Years' Average.	Merchandise. Imports.	Merchandise. Exports.	Merchandise. Excess Exports.	Treasure. Net Imports.	Excess Exports, Merchandise and Treasure.
	Rx.	Rx.	Rx.	Rx.	Rx.
1869–70 to 1873–74	33,036,588	56,252,723	23,216,135	6,674,240	16,541,895
1874–75 to 1878–79	38,363,836	60,324,893	21,961,057	7,048,286	14,912,771
1879–80 to 1883–84	50,154,241	79,084,526	28,930,285	10,333,962	18,596,323

Total exports . .	111,460,278	104,781,428
Total sea-borne trade	195,615,323	198,972,505

Under imports, the most notable feature is the increase in Government stores, representing larger railway construction by the State. Under exports, the decrease in Indian produce and manufactures is probably temporary, being due to famine and plague ; but the decrease in foreign produce and manufactures shows a permanent change in the character of the re-export trade, Bombay having lost much of its *entrepôt* business with the east coast of Africa and the Persian Gulf.

The re-exports of foreign produce and manufactures reached their maximum of Rx.5,057,414 in 1894–95, and then fell year by year to only Rx.3,292,491 in 1899–1900.

The following table gives the value (in tens of thousands of rupees) of the chief articles of import for the years named :—

Values of Principal Imported Articles.

Articles.	1889-90.	1894-95.	1899-1900.
	Rs.10,000.	Rs.10,000.	Rs.10,000.
Apparel	1,296	1,435	1,464
Books, &c.	855	869	933
Coal	1,309	1,474	810
Cotton twist, &c.	3,483	2,851	2,460
Cotton piece-goods	26,391	29,822	27,002
Hardware, &c.	1,096	1,333	1,590
Liquors	1,465	1,458	1,597
Machinery, &c.	2,435	2,442	2,542
Iron	2,414	2,245	2,420
Steel	328	586	1,000
Copper	2,222	1,512	629
Mineral oils	2,479	2,123	3,180
Provisions	1,597	1,576	1,689
Railway materials	1,821	1,557	2,776
Silk manufactures	1,778	1,277	1,129
Raw silk	1,067	1,037	576
Sugar	2,200	2,875	3,376
Woollen manufactures	1,455	1,542	1,758

Cotton manufactures of all kinds still form 42 per cent. of the total imports, but ten years earlier the proportion was as high as 45 per cent. The value of piece-goods reached its maximum in 1894–95, and has since fluctuated considerably. The value of twist and yarn first fell under competition with the product of local spinning mills, and then rose again when local weaving mills began to use the finer counts of English yarn. At a long distance after cotton manufactures, the next most important article of import is metals of all kinds, which now form normally 7 per cent. of the total. Here the largest increase is under the head of steel. Hardware and cutlery, machinery and mill-work, each show fair increases, while railway plant and rolling stock are subject to fluctuations. Mineral oils have considerably increased, despite a heavier import duty; and sugar increased yet more considerably, partly under the stimulus of Continental bounties, which are now met by a countervailing duty. Both raw silk and silk manufactures show a heavy decrease. But the most significant decrease is in coal, which is little more than half of what it was in some earlier years. The mines of Bengal are now almost entirely able to supply the railways and mills of all India.

The following table gives the value (in tens of thousands of rupees) of the chief articles of export for the same years :—

Values of Principal Exported Articles.

Articles.	1889-90.	1894-95.	1899-1900.
	Rs.10,000.	Rs.10,000.	Rs.10,000.
Coffee	1,500	2,209	1,506
Raw cotton	18,671	8,708	9,925
Cotton twist	5,840	5,784	7,008
Cotton manufactures	2,733	3,600	2,611
Indigo	3,863	4,746	2,692
Rice	10,110	13,815	13,101
Wheat	5,793	2,566	3,909
Hides	4,524	6,560	10,464
Raw jute	8,640	10,576	8,071
Jute manufactures	2,791	4,211	6,265
Lac	489	1,406	1,137
Opium	10,116	9,065	8,203
Oil-seeds	10,631	14,206	10,110
Tea	5,445	7,989	9,177
Wood	875	665	1,096
Raw wool	1,779	2,016	1,801

Here rice takes the first place, with a steady average of about 12 per cent. of the total value. It should be borne in mind that rice is the only article subject to an export duty. Even the famine of 1896–97 hardly checked the export of rice from Burma to foreign countries. The quantity of rice exported reached its maximum (38,000,000 cwts.) in 1898–99. Raw cotton falls to the second place, owing to its wide fluctuations. The maximum quantity was over 6,000,000 cwts. in 1889–90, which fell to only 3,000,000 cwts. in 1894–95 and again in 1897–98. The next place is held by oil-seeds, which similarly fluctuated from a maximum of 24,000,000 cwts. in 1893–94 to a minimum of 11,000,000 cwts. in 1896–97. Raw jute shows a steady increase, the quantity having reached its maximum (15,000,000 cwts.) in 1897–98. Tea also shows a steady increase, the quantity having risen almost year by year from 105,000,000 ℔ in 1889–90 to 176,000,000 ℔ in 1899–1900. Hides increased considerably, but the very high figure for 1899–1900, explained by the mortality of cattle from drought, is by no means a sign of prosperity. Wheat is liable to excessive fluctuations; from a maximum quantity of 30,000,000 cwts. in 1891–92 to only 2,000,000 cwts. in each of the two years 1896–97 and 1897–98. Opium shows a decrease, from 118,598 cwts. in the first year to 93,378 cwts. in the last. Indigo shows wide fluctuations, from a maximum quantity of 187,337 cwts. in 1895–96 to a minimum of 111,420 cwts. in 1899–1900. The most remarkable increase of all is in manufactures of jute, the produce of the mills near Calcutta, which more than doubled in value. The export of jute cloth (as opposed to bags) increased in ten years from 37 to 307 million yards. Cotton piece-goods show a decrease in value, which was very marked during the last five years. The decrease in quantity was from a maximum of 193 to a minimum of 130 million yards. Cotton twist and yarn, on the other hand, show a fair increase, the quantity having risen from 143 to 243 million ℔. Coffee fluctuated, with a tendency to decrease. The maximum quantity was 367,480 cwts. in 1888–89; the minimum was 215,896 cwts. in 1896–97. Raw wool, lac, and timber each show an increase. In quantity, lac of all kinds rose in ten years from 90,240 to 238,450 cwts., and teak timber from 71,402 to 77,822 cubic tons. Among minor articles, not specified in the above table, sugar, spices, dyes (other than indigo), raw silk, and silk manufactures all show decreases. Manures (chiefly animal bones), oils, and tobacco each show an increase; but the total export of tobacco in 1899–1900 was only 10,000,000 ℔, valued at Rx.184,465. In the same year the export of coal was 218,877 tons, valued at Rx.328,315.

The proportion of trade that passes through the Suez Canal remains fairly constant at about 80 per cent. for imports and 57 per cent. for exports. The following table distributes the imports according to the countries from which they were received in each of the three years 1877–78, 1887–88, and 1897–98 :—

Country.	1877-78. Value.	Percentage of Total	1887-88 Value.	Percentage of Total.	1897-98. Value.	Percentage of Total
	Rx.		Rx.		Rx.

Total	41,464,182		65,004,612		73,660,460	

During the first period of ten years the increase in the imports from the United Kingdom almost kept pace with the increase in the total imports, but during the second period of ten years the imports from the United Kingdom decreased absolutely, while their proportion to the total fell from 80 to 69 per cent. What the United Kingdom lost was gained by Germany, Belgium, Austria-Hungary, Russia, and unnamed countries (including Japan). The imports from other countries show little variation.

The following table distributes the exports according to countries for the same years :—

Country.	1877-78. Value.	Percentage of Total.	1887-88. Value.	Percentage of Total.	1897-98. Value.	Percentage of Total.

Total	65,222,328		90,543,655		97,632,781	

Here the decline of trade with the United Kingdom is still more marked, its proportion to the total having steadily fallen from 46 to 31 per cent. The shares of China and of France also decreased. Germany and Belgium again gained most; while the United States also show a large increase. The exports to Egypt are probably for distribution to Mediterranean ports. The growing trade with Japan is concealed under "other countries." In 1899–1900 the exports to Japan were valued at Rx.6,336,664, almost entirely raw cotton, with some indigo and rice. In 1890–1891 the total value was only Rx.1,210,276.

Turning to the more important articles of *import*. In 1897–98 the United Kingdom sent 97 per cent. of the cotton piece-goods, the remainder coming chiefly from the United States and Austria-Hungary; and likewise 97 per cent. of the cotton twist and yarn. Of railway material, and also of machinery and millwork, the share of the United Kingdom was as large as 99 per cent.; but in the case of hardware and cutlery it dropped to 78 per cent., in iron to 75 per cent., in copper to 70 per cent., and in steel to 50 per cent. In iron, steel, and copper the most formidable competitor of the United Kingdom was Belgium. The imports from Germany consisted mainly of sugar and miscellaneous articles. The importation of sugar from Austria-Hungary suddenly rose from Rx.131,379 in 1896–97 to Rx.1,044,504 in 1897–98, or eightfold in a single year. Russia now sends nearly three times as much mineral oil as the United States.

As regards the *exports*, cotton twist and yarn were sent almost entirely to China; cotton piece-goods to the neighbouring countries of Asia and Africa; raw cotton to Japan and the Continent. Of raw jute, the United Kingdom took more than one half, and Germany nearly one-fifth; gunny cloth went mainly to the United States, while Australia was the chief market for gunny bags. Rice went to Egypt (for transhipment), Ceylon, the Straits, the United Kingdom, Brazil, Mauritius, and Arabia. Of the exports of tea, no less than 92 per cent. went to the United Kingdom, and 3 per cent. to Australia; but some success attended the efforts to open up a market in the United States and Canada. Of oil-seeds, the United Kingdom took the largest proportion of linseed; but rape, sesamum, castor, and poppy went mainly to France and Belgium. The export of dressed hides was mainly to the United Kingdom, and to the United States in the second place; while Germany took the largest amount of raw hides, with the United States again in the second place. Wheat went mainly to the United Kingdom and other countries in Europe.

The following table distributes the total foreign trade (in merchandise only) among the 16 principal seaports for the two years 1887–88 and 1897–98:—

Port.	1887–88.		1897–98.	
	Value.	Percentage of Total.	Value.	Percentage of Total.
	Rx.		Rx.	
Calcutta	58,955,852	38·6	71,994,608	43·1
Bombay	59,654,586	39·0	52,063,062	31·2
Rangoon	9,897,716	6·5	12,346,725	7·4
Madras	8,800,123	5·7	10,161,018	6·1

Mangalore	319,171	·2	549,060	·3
Tellicherri	737,557	·5	542,183	·3
Akyab	939,065	·6	374,624	·2
Total	151,166,569	98·9	164,958,831	98·8
Grand Total for British India	152,856,275		166,957,393	

The two great rivals, Calcutta and Bombay, control between them three-fourths of the total trade of India. But while the share of Calcutta has steadily increased, Bombay suffered severely from the combined effects of famine and plague. Rangoon has gained upon Madras, and Karachi comes close behind. Of the minor ports, Tuticorin and Cochin (both in the Madras Presidency) show the largest increase; while Chittagong, Akyab, and Tellicherri conspicuously declined.

Shipping.—The following table distributes according to national flags the vessels (both steam and sailing) that cleared for foreign countries from British India in each of the three years 1877–78, 1887–88, and 1897–98:—

National Flag.	1877–78.		1887–88.		1897–98.

Turkish	7	5,275	25	7,138	2	1,759
British Indian	1,950	97,278	1,647	72,660	1,201	61,071
Foreign Indian	77	7,158	158	14,547	131	13,848
Others	2	1,577	2	226	...	...
Total	6,184	2,876,730	5,585	3,675,251	4,784	3,866,869

In this case the United Kingdom holds its own. Though the number of British-owned vessels (including those registered in British India) decreased, the aggregate tonnage rose, and the proportion which this bore to the total remained pretty constant. Here again the most notable increase is shown by Germany, closely followed by Austria-Hungary. France, Italy, and Sweden each declined, while American ships dropped from 65 to 1. The fall under British Indian is probably a result of re-classification.

Treasure.—The following table gives the imports and exports of treasure, distinguishing gold and silver, for each of the ten years ending 1899–1900. During the 50 years ending 1898–99, India imported treasure to the aggregate value of Rx.524,000,000. In no year of that period did the imports of treasure fail to exceed the exports; but in 1894–95, the year after the mints were closed, the net imports dropped to Rx.1,355,135. The net imports first rose above Rx.10,000,000 just before the Mutiny, when railway construction was beginning; and first rose above Rx.20,000,000 at the time of the American Civil War. During the decade ending 1868–69, the net imports of gold averaged nearly Rx.6,000,000 a year, and the net imports of silver averaged more than Rx.10,000,000 a year. The closing of the Indian mints to the free coinage of rupees in June 1893 has had the effect of reducing the net imports of silver, which now possesses only a bullion value, and of increasing the net imports of gold.

Year.	Imports. Gold.	Imports. Silver.	Exports. Gold.	Exports. Silver.	Net Imports. Gold.	Net Imports. Silver.

Coasting Trade.—The following table analyses the total coasting trade of India for the two years 1888–89 and 1897–98. During ten years the aggregate coasting trade increased by 19 per cent. Taking country produce only, imports increased at the rate of 30 per cent., and exports at the rate of 39 per cent. In foreign products, imports showed a slight decrease, and exports a somewhat larger increase. Government transactions increased considerably. The heavy fall in treasure was probably due to the closing of the mints.

		1888–89.	1897–98.
Imports—		Rx.	Rx.
Private Merchandise	Country .	23,136,488	30,015,652

The following table distributes among provinces the coasting trade for 1897–98, excluding Government transactions:—

Province.	Imports. Merchandise. Country.	Imports. Merchandise. Foreign.	Imports. Merchandise. Total.	Imports. Treasure.	Exports. Merchandise. Country.	Exports. Merchandise. Foreign.	Exports. Merchandise. Total.	Exports. Treasure.
	Rx.	Rx.	Rx.	Rx.	Rx.	Rx.	Rx.	Rx.
Bengal . .	7,292,856	831,412	8,124,268	538,347	6,631,623	1,409,167	8,040,790	1,270,963
Bombay .	12,131,453	630,633	12,762,086	259,278	8,473,451	4,610,375	13,083,826	431,616
Sind . .	1,139,744	1,620,996	2,760,740	78,827	2,491,478	165,118	2,656,596	7,973
Madras .	4,835,330	1,183,163	6,018,493	91,571	4,817,536	250,743	5,068,279	61,717
Burma . .	4,616,269	1,105,876	5,722,145	1,025,249	6,736,676	677,808	7,414,484	441,990
Total .	30,015,652	5,372,080	35,387,732	1,993,272	29,150,764	7,113,211	36,263,975	2,214,259

This table brings out the varying character of the coasting trade in the several provinces. Bombay, with its line of active little ports all along the western coast, from Kathiawar to Kanara, possesses more than one-third of the whole; but owing to the prevalence of plague, its share of the total imports fell from 44 to 36 per cent. Trade is also active along both coasts of Madras, but no increase was shown during 1894–98. In Bengal (where the only ports besides Calcutta are Chittagong and the Orissa roadsteads), the imports of country produce increased between 1894 and 1898 by 50 per cent., and the exports by 40 per cent. Sind (which means Karachi) imports a larger amount of foreign than of country merchandise, standing alone in this respect; while its exports, which more than doubled in 1894–98, are almost entirely confined to country produce. In both cases the trade is carried on with Bombay. In Burma the coasting trade in foreign produce remained stationary, the imports being approximately double the exports. The exports of country produce mainly depend upon the demand in India for Burmese rice, and fluctuated within three years from under Rx.3,000,000 to nearly Rx.7,000,000. The imports showed a steady increase, at the rate of 31 per cent. in 1894–98. The coasting trade in treasure consists almost entirely of an export from Bengal to Burma, to move the rice crop.

Trans-frontier Trade.—The following table gives the registered imports and exports by land along the northern frontier of British India, from Sind to Burma, for the two years 1891–92 and 1897–98. The largest portion of this land trade is conducted with Nepal, which sends to Bengal and the North-Western Provinces rice, timber, cattle, oil-seeds, *ghi*, &c., and receives in exchange cotton, silver, salt, metals, sugar, spices, and tobacco. The trade with independent Afghanistan shows a steady decline, due to the restrictions imposed by the Amir. On the other hand, the trade with Tirah and Bajaur (Afghan territory under British influence) shows satisfactory improvement. The trade with Tibet and Sikkim increased; but that with Bhutan and along the frontier of Assam is insignificant. Along the frontier of Burma trade is comparatively active, especially with the Shan States; but it should be remembered that the Shan States are not foreign territory. Of the total exports of merchandise, nearly one-half consist of cotton goods. The imports and exports of treasure appear to be almost equally balanced.

Finance. Between 1880 and 1899 the gross revenue increased at the rate of 48 per cent., while the expenditure increased at the rate of 61 per cent. Of these twenty years eleven were years of surplus and nine were years of deficit, the net deficit being Rx.2,026,549. If we go back for a further period of thirty years, *i.e.*, to 1849–50, the net deficit has amounted to Rx.4,000,000; but it has to be remembered that a deficit of no less than Rx.32,000,000 was incurred in the three years following the outbreak of the Mutiny.

As the gross revenue and expenditure of India include large sums on both sides of the account for railways and other commercial services, it will be convenient to consider the chief items separately. The following table gives the principal heads of both revenue and expenditure for the five years named :—

Head.	1877–78.	1882–83.	1887–88.	1892–93.	1897–98.

Between 1878 and 1898 the land revenue increased by just Rx.6,000,000, but the proportion which it bore to the total gross revenue fell from 34 to 27 per cent. Forests largely increased, especially since 1890. The small increase in tributes is mainly due to the recent levy of the full assessment upon Mysore. Opium decreased very heavily, especially in the last five years, and the proportion which it bore to the total revenue fell from 14 to 5 per cent. The fluctuations in salt were partly due to changes in the rate of duty, which is now levied uniformly (except in Burma) at Rs.2 : 8 : 0 per maund. Stamps steadily increased, the rate of increase during the period being no less than 62 per cent. Nearly two-thirds of the

whole is derived from judicial or court-fee stamps. Excise more than doubled in the twenty years, but the recent famine caused an actual decline. It is levied on liquors, opium (for local consumption), and other intoxicating drugs. The increase is attributed to more effective control of the administration, thus checking illicit manufacture, rather than to increased consumption. The policy of the State is to increase progressively the rates of duty, according as the articles will admit. The fluctuations under customs are due to changes of financial policy. From 1875 to 1882 there was a general import duty of 5 per cent. In 1882 all articles were admitted free, except liquors, arms, opium, and salt, and all exports were freed from duty, except rice. In 1894 the former tariff of 5 per cent. was reimposed, subject to certain exceptions. In 1896 cotton yarn was exempted from duty, and the rate on all other cotton goods was reduced to 3½ per cent. In 1899 (subsequent to the period covered by this table) sugar imported from countries which grant a bounty on exportation was charged with an additional duty equivalent to the bounty, which is estimated to yield about Rx.170,000 a year. In 1897–98, out of a total customs revenue of Rx.4,641,295, the export duty on rice yielded Rx.723,731. Of the import duties, cotton manufactures yielded Rx.795,721; liquors, Rx.661,317; metals, Rx.577,553; petroleum, Rx.531,778; and sugar, Rx.246,045. The present income tax was first imposed in 1886, in substitution for various licenses on trades. It is levied at the rate of 5 pies in the rupee (say 6d. in the £) on incomes exceeding Rs.2000, and at the rate of 4 pies in the rupee (say 5d. in the £) on incomes exceeding Rs.500, below which there is total exemption. In 1897–98 the total number of persons assessed under the tax was only 462,383, and the average incidence of the demand was Rs.36 per person assessed.

The table at the bottom of the previous page shows the revenue and expenditure of the commercial services which are included in the Indian budget for the same five years. It will be observed that post-office, telegraphs, and irrigation each yielded a net profit in 1897–98, and that the loss on railways has steadily diminished. Within the period the gross revenue from the post-office more than doubled; from telegraphs it multiplied nearly fourfold; from railways nearly threefold; and from irrigation more than threefold. These figures are, of course, exclusive of capital expenditure.

The two following tables show the net revenue and net expenditure for 1899–1900, according to the form in which the accounts are now laid before Parliament, 15 rupees being taken as the equivalent of £1:—

Net Revenue, 1899–1900.

Land Revenue, &c.—		
Land	£16,444,825

Grand Total		£38,212,075
Surplus		2,574,623

As compared with the preceding year (1898–99) the total net revenue shows a decrease of £892,919, due mainly to a heavy fall under land, against which may be partly set off improvements under opium and mint. The total net expenditure shows a decrease of £1,026,669, of which £1,189,110 was under army and £723,473 under commercial services, while £1,307,305 more was spent on famine relief.

Debt.—The total debt consisted in 1898 of Rx.111,695,634 in India and £123,274,680 in Great Britain, of which Rx.131,030,304 was appropriated to railways and Rx.32,639,803 to irrigation, leaving Rx.65,300,207 for other purposes. During the ten years 1889–98 the debt in India increased by about Rx.11,000,000, and the debt in England by more than £28,000,000. Almost all the debt in India bears 3½ per cent. interest, the rate having been reduced from 4 per cent. in 1894. The debt in England bears interest at rates varying from 3½ to 2½ per cent. In 1897–1898 the total payments on account of interest amounted to Rx.10,695,520, of which Rx.5,939,011 was debited against railways and Rx.1,284,249 against irrigation, leaving Rx.2,957,024 for interest on ordinary debt and Rx.515,236 for interest on other obligations. Since 1887–88, owing to the reduction in the rate of interest, the charge for ordinary debt has fallen by more than Rx.2,000,000. Of the total debt in India, Rx.21,780,893 was in 1898 enfaced for payment of interest in London, and of the remainder it is estimated that Rx.47,804,990 is held by natives, while about Rx.10,000,000 is held in reserve by the Government against paper currency.

The expenditure of the Indian Government in England is for the most part met by means of bills (or telegraphic transfers) drawn on India by the Secretary of State, and sold by him in London for sterling. During the 25 years ending 1897–98 the total amount of such bills was Rs.482,91,57,513, and the total amount of sterling received for them was £353,271,946. The difference between these two figures (Rs.12,96,43,805) represents the "loss by exchange" on the conventional value of the rupee at 2s. During the 25 years the average annual rate obtained per rupee ranged from 1s. 10·351d. in 1873–74 to 1s. 1·100d. in 1894–95. Since the closing of the Indian mints to the free coining of rupees in June 1893 the exchange value of the rupee has been gradually dissociated from the market price of silver, and during 1900 stood pretty steadily at 1s. 4d. This is the rate at which, by Indian legislation, sovereigns were made legal tender, £1 being the equivalent of Rs.15; and the accounts of the Indian Government, as laid before Parliament, are now expressed in pounds sterling on this basis.

Savings Banks.—In 1897–98 there were 6484 Government savings banks in India, mostly connected with the Post Office. The total number of depositors or accounts was 755,426, and the balance at the end of the year was Rx.10,556,733, being an average of Rs.139 for each depositor. About 90 per cent. of the depositors, with 82 per cent. of the deposits, are natives of India. The rate of interest allowed is 3⅛ per cent., and the maximum amount receivable from any one depositor is Rx.200.

Notation.—In India the method of pointing a statement of rupees differs from the English system. Up to 99,999 the figures are named and pointed as in English, but 100,000 rupees is termed a *lakh* (or *lac*) and written 1,00,000. Millions are not named in the Indian notation. Thus 1234567 would not be punctuated 1,234,567, but Rs.12,34,567, reading "Twelve lakhs, thirty-four thousand, five hundred and sixty-seven" rupees. The *crore* (Indian *karōr*) is equal to 100 lakhs. Thus Rs.1,23,45,678 would read "One crore, twenty-three lakhs, forty-five thousand, six hundred and seventy-eight" rupees (English notation 12,345,678). In the case of very large numbers, such as Rs.28332415000, a change is introduced. This would be written Rs.2,833,24,15,000, and read "Two thousand eight hundred and thirty-three crores, twenty-four lakhs, fifteen thousand." This system is also sometimes used in enumerating bales of goods, such as jute or cotton, but is never applied to populations.

Army.—The net expenditure on the army was, during 1899–1900, £14,166,617, of which £4,061,817 was spent in Great Britain and £10,824,283 in India. In 1897 the death-rate was 12·75 per thousand for the European army, and 10·70 per thousand for the native army. (For full details see article on Armies.)

Police and Prisons.—The total police force of all kinds (excluding village watchmen) consisted in 1899 of 150,016 officers and men, of whom 47,354 were armed with firearms and 38,487 with swords. The total cost was £2,093,968. Compared with 1889, the numbers increased in ten years by 3 per cent., while the cost increased by 17 per cent. The total daily average number of prisoners in all the gaols in 1899 was 104,119, of whom 2770 were females. The death-rate was 22 per thousand, being lower than in any year of the previous decade. The total expenditure was Rs.61,79,357, being Rs.59·10 per head of average strength. Compared with 1889, the numbers increased by 25 per cent. and the cost by 27 per cent.

Posts and Telegraphs.—The following is a comparison of the general statistics of the Imperial Post Office in British India in 1899–1900 compared with 1890–91. The number of post-offices increased in ten years from 8394 to 10,823, or 29 per cent.; of letter-boxes from 11,999 to 19,822, or 65 per cent.; the strength of the establishment increased from 44,979 to 55,073, or 22 per cent. The length of railways, roads, &c., over which the mails were conveyed increased from 74,393 to 91,534 miles, or 23 per cent.; the total number of letters, &c., received for delivery from 325,000,000 to 521,000,000, or 60 per cent.; the gross revenue from Rx.1,396,385 to £1,299,609, or approximately 40 per cent.; and the gross expenditure from Rx.1,177,694 to £999,113, or approximately 27 per cent. The surplus thus grew from Rx.218,691 to £300,496. The rate of postage, extending over the whole of British India, is half an anna (say ½d.) for a weight not exceeding half a tola, and one anna (say 1d.) for every one and a half tolas; while a postcard, including the cost of the card, costs only 3 pies (say ¼d.).

The following are the corresponding statistics for government telegraphs:—During the ten years from 1890–91 to 1899–1900 the length of lines increased from 37,070 to 52,909 miles, or 43 per cent.; the length of wires from 113,512 to 170,766 miles, or 50 per cent.; the length of cable from 251 to 283 miles, or 13 per cent.; the number of signal offices open from 949 to 1851, or nearly twofold; the number of messages from 3,403,769 to 6,237,301, or 83 per cent.; the revenue from Rx.569,081 to £565,676, approximately 50 per cent.; and the working expenses from Rx.468,880 to £447,758, or 43 per cent. The surplus thus rose from Rx.100,201 to £117,918, while, as the capital expenditure increased from Rx.5,024,168 to £4,510,939, the interest on capital outlay advanced from 1·99 to 2·61 per cent. The ordinary rate of charge for telegraphing throughout the whole of British India (including Burma) is one rupee for eight words, the address being free, with two annas for each additional word. The "urgent" rate is double this, and the "deferred" rate one half.

Municipalities.—The following table gives the chief statistics of municipalities in India, according to provinces, for 1899–1900:—

Province.	Number of Municipalities.	Population.	Income. From Taxation.	Income. From other Sources.	Income. Total.	Incidence of Taxation per Head.
			Rx.	Rx.	Rx.	Rx.
Bengal	152	3,379,749	759,729	512,372	1,272,101	2·25
N.W. Provinces and Oudh	104	3,235,685	372,763	110,617	483,380	1·25
Punjab	148	2,086,327	325,967	165,529	491,496	1·56
Burma	42	865,822	194,006	328,168	522,174	2·24
Central Provinces	52	683,739	112,247	37,947	150,194	1·64
Assam	14	84,727	11,164	14,312	25,476	1·32
Madras	59	2,154,920	275,496	420,651	696,147	1·28
Bombay	166	3,058,311	1,204,880	2,941,180	4,146,060	3·94
India, General	20	283,344	34,207	13,335	47,542	1·21
Total	757	15,832,624	3,290,459	4,544,111	7,834,570	2·08

Since 1890–91 the population within municipal limits has increased by 6 per cent., while the income from taxation has increased by 42 per cent., and the total income by 158 per cent. In 1899–1900 the chief items of expenditure were: conservancy, Rx. 896,139; roads, Rx. 396,886; water-supply, Rx. 332,716; drainage, Rx. 319,525; hospitals, Rx. 300,776; education, Rx. 255,478; lighting, Rx. 175,354; police, Rx. 166,507.

Education.—The following table gives the chief educational statistics for the three quinquennial years 1886-87, 1891–92, and 1896–97:—

Public Institutions.	1886–87. Institutions.	1886–87. Pupils.	1891–92. Institutions.	1891–92. Pupils	1896–97. Institutions.	1896–97. Pupils.
Colleges	114	11,501	141	16,277	160	18,783
Secondary schools	4,517	429,093	4,872	473,294	5,267	535,155
Primary schools	89,187	2,513,934	97,109	2,837,607	103,920	3,209,825
Training schools	141	5,123	152	5,146	184	5,667
Special schools	329	11,208	402	16,586	355	18,952
Total	94,288	2,970,859	102,676	3,348,910	109,886	3,788,382
Private institutions	32,828	372,685	39,117	507,911	42,139	568,488
Grand Total	127,116	3,343,544	141,793	3,856,821	152,025	4,356,870

During the whole period of ten years the total number of pupils at school increased by just over one million, or at the rate of 30 per cent. Schools did not increase quite so fast, but show a steady improvement in the average strength of each institution. The average attendance at colleges rose from 101 to 117; in secondary schools, from 95 to 102; and in primary schools, from 28 to 31. Assuming the number of persons of school-going age to be 15 per cent. of the total population, the proportion of these actually attending school rose from 10·7 to 12·5 per cent. The total number of girls attending school increased during the ten years from 266,287 to 402,158, or 51 per cent., while their proportion to the estimated female population of school-going age rose from 1·7 to 2·3 per cent. Mahommedans are specially numerous in private institutions, and hold their own in primary schools, but in secondary schools and colleges their proportion steadily falls. Native Christians are well represented throughout. In 1896-97 the total number of pupils learning English was 438,846 (chiefly in Madras and Bengal), being 1 in 79 of the total population of school-going age. There are now five universities in India, which are purely examining bodies, modelled on the pattern of the London University. During the ten years ending 1896–97, the total number of candidates who passed the matriculation was 57,919; of those who passed an intermediate examination, 21,240; of those who graduated B.A., 10,884; of those who proceeded to the degree of M.A., 917. Colleges and schools are classified according to their management. In 1896–97 only 2 per cent. of the total number of pupils were in institutions under the direct management of the State; 22 per cent. were in institutions under district boards or municipalities; 47 per cent. were in "aided" institutions; 12 per cent. in institutions that receive no assistance from the State but submit to public inspection; 13 per cent. in private institutions; and 4 per cent. in native States. It has long been the policy of the Government to withdraw from active management. The institutions which it still maintains belong to three classes: (1) a few arts colleges and English secondary schools, which are necessary in order to preserve a high standard of instruction; (2) primary schools in backward tracts or for backward sections of the population; and (3) special institutions, such as medical and engineering colleges and training schools.

The following table classifies the expenditure on education for the three quinquennial years 1886–87, 1891-92, and 1896–97. During the whole period of ten years the total expenditure increased by just a crore of rupees, or at the rate of 40 per cent. As the rate of increase in pupils was only 30 per cent., it is evident that education is tending to become more expensive,

as must inevitably be the case as it becomes more efficient. Nevertheless, the average cost per head of population in 1896–97 was only Rs.0:2:5 (say 2½d.). It will be observed that the rate of increase has been much the highest under the two last headings, fees and "other sources," the latter of which includes subscriptions and endowments, missionary contributions, and grants from the revenues of native States. These two headings now contribute more than half of the total expenditure, the actual proportion having

Source.	1886–87.	1891–92.	1896–97.
	Rs.	Rs.	Rs.
Provincial revenues .	85,61,249	88,13,549	95,22,985
Local funds . .	37,14,579	53,94,808	57,45,944
Municipal funds .	12,05,984	14,09,827	14,96,721

Other sources . .	52,30,644	60,46,698	78,68,317
Total . .	2,52,42,414	3,05,19,632	3,52,44,900

risen in ten years from 46·6 to 52·4 per cent. Of the total expenditure in 1896–97, 7 per cent. was devoted to arts colleges, 32 per cent. to secondary schools, 31 per cent. to primary schools, and 5 per cent. to special schools. Examined from another point of view, public funds provided 51 per cent. of the cost of colleges, 28 per cent. of the cost of secondary schools, and 52 per cent. of the cost of primary schools. The universities are almost all self-supporting, the total cost being more than balanced by fees.

The following table distributes the pupils for 1896–97 according to provinces, separating the boys from the girls, and giving the percentage of each to the estimated population of school-going age (15 per cent. of the total population):—

Province.	Boys.	Girls.	Total.	Percentage to estimated Population of School-going Age.		
				Boys.	Girls.	Total.
Madras	706,106	116,747	822,853	26·7	4·3	15·4
Bombay . . .	590,542	82,163	672,705	28·3	4·2	16·6
Bengal	1,561,008	113,767	1,674,775	28·5	2·0	15·2

The high position taken by Burma is due to the prevalence of Buddhism, which demands that all young boys shall pass a period of literary training in a monastery, where they are taught Pali, the sacred language, as well as the vernacular. In respect of secondary education Burma takes a very low place. In justice to Bombay it should be stated that the outbreak of the plague closed nearly all the schools in Bombay city and Poona, the centres of higher instruction. Excluding Burma and Coorg, where the circumstances are peculiar, Madras and Bombay contest the lead in the matter of female education. Each of them has twice the proportion of girls at school that Bengal has, and eight times the proportion of the North-Western Provinces. During the last few years the Punjab has shown the most rapid progress, especially in the local support given to English-speaking schools.

Plague and Famine.—During recent years India has suffered severely from both plague and famine. Bubonic plague first declared itself in an epidemic form at Bombay city in September 1896, having probably been introduced from Hong Kong. Since that time the western presidency has never been entirely free from the disease, which has now also extended to other parts of India. From September 1896 to April 1901, or for just four and a half years, the total number of recorded deaths from plague was 480,000, of which no fewer than 336,000 were in the presidency of Bombay. Elsewhere epidemic outbreaks have been confined to Bangalore, parts of Mysore State, and (at a later date) Calcutta and separate tracts in North and South Behar. In the western presidency the city of Bombay itself and the towns of Karachi and Poona have suffered most severely, together with the districts of Satara and Belgaum and the native State of Cutch. In 1902 plague extended to the Punjab in a severe form.

The effects of famine, which are far more widespread than those of plague, have made themselves felt twice within three years. The two famines of 1896–97 and 1899–1900 were both directly caused by drought. On the former occasion the region of extreme distress was confined to the Central Provinces, the North-Western Provinces, and the native States of Bundelkhand that lie between. Elsewhere, as in the Bombay Deccan, the Northern Circars of Madras, and some districts of Bengal and the Punjab, the drought was more or less severe. But the total area in which famine was officially recognized extended over nearly 400,000 square miles, being considerably larger than on any former occasion known to history. The total expenditure by the Government on famine relief during the two financial years 1896–97 and 1897–98 amounted to no less than Rx.7,405,133 (nearly £5,000,000 sterling). In the Central Provinces alone the total cost of the famine is calculated at 2½ crores of rupees. Here, mainly owing to the difficult nature of the country and the shyness of the aboriginal tribes, the efforts of the Government to save life failed of complete success. In 1896 the death-rate rose to 49·3 per 1000, and in 1897 there was a further rise to 69·3 per 1000 for the whole province, the rate in two districts being above 90 and in three districts above 80. These figures speak for themselves, especially when it is stated that in the worst district of the North-Western Provinces the death-rate for 1897 was only 61·8, and for the whole province only 40·5 per 1000. The famine of 1899–1900 is estimated to have extended over a total area of nearly 700,000 square miles. The Central Provinces were again included within the region of distress, though the North-Western Provinces altogether escaped. Almost the whole of Bombay suffered, more or less severely; also Berar, Haidarabad, and part of the Punjab. But the zone of extreme distress ran from Kathiawar on the western coast, through Northern Gujarat, into the native States of Rajputana and Central India. Here the deficiency of rainfall not only caused the harvest to fail and the cattle to perish of starvation, but also reduced the water-supply to such an extent as to expose the unhappy people to the ravages of cholera. During the financial year 1900–1901, the direct expenditure on famine relief was Rx.6,337,600, besides Rx.1,471,600 for remissions and suspensions of revenue, and Rx.660,300 for compensation charges: total, Rx.8,469,500. In addition, Rx.4,110,000 was advanced in loans to native States, and Rx.1,420,000 to agriculturists. Altogether, the drain on the balances caused by famine is estimated to have amounted for two years to nearly £14,000,000 sterling. The total number of deaths due to famine, directly or indirectly, is believed to have been about 1,000,000. The following table shows the distribution of persons in receipt of relief in July 1900, when distress was at its height:—

Province.	Relief Works.	Gratuitous Relief.	Total.
BRITISH PROVINCES—			
Madras . . .	8,633	3,060	11,693
Bombay . . .	1,168,995	456,644	1,625,639

Grand Total .	3,476,117	2,880,882	6,356,999

Vital Statistics.—For several years past vital statistics have been collected throughout British India, through the agency of the police. Though considerable improvement in accuracy has been attained, the returns cannot be considered as trustworthy, especially as regards the number of births and the causes of death. For comparative purposes, however, the number of registered deaths is worthy of attention. This is shown in the following table for each of the ten years ending 1899. During these ten years the total population under registration has increased from 194,000,000 to 214,000,000, mainly by adopting the results of the census of 1891. Registration has not yet been extended to Upper Burma, or to some small tracts in other provinces.

Year.	Deaths from Different Causes.							Ratio of Total Deaths per 1000 of Population.
	Cholera.	Smallpox.	Fevers.	Dysentery and Diarrhœa.	Injuries.	All other Causes.	Total Deaths.	
1890	292,528	120,554	4,110,044	230,899	87,495	1,091,609	5,933,129	29·99
1891	583,634	98,844	3,822,358	244,889	89,184	1,114,620	5,953,529	28·09
1892	729,512	101,142	4,629,201	236,734	86,318	1,216,058	6,998,965	32·12
1893	217,507	68,819	3,761,724	201,127	89,498	1,223,932	5,562,607	25·52
1894	521,975	43,623	4,987,304	261,996	93,110	1,393,162	7,301,170	33·49
1895	313,131	44,979	4,255,030	242,020	94,147	1,280,758	6,230,065	28·60
1896	471,767	137,622	4,569,541	239,810	92,251	1,356,834	6,867,825	31·65
1897	555,016	167,160	5,015,842	403,394	115,691	1,475,042	7,732,145	36·03
1898	150,817	55,713	3,817,456	209,035	91,604	1,344,927	5,669,552	26·44
1899	169,237	49,560	4,085,455	244,920	95,524	1,792,726	6,437,422	30·01

It will be observed that the death-rate rose to its maximum in 1897, which was a year of famine, and that the deaths from every cause showed an increase in that year. The largest number of deaths from cholera (729,512) was in 1892, when there was a severe epidemic throughout Northern India; the smallest number (150,817) was in 1898. The number of deaths from smallpox ranged from 43,623 in 1894 to 167,160 in 1897, when there was a very severe outbreak in the North-Western Provinces, causing more than half the total number of deaths.

The following table gives the death-rate per 1000, according to causes, for each of the different provinces in 1897. The variations from the average may fairly be taken as evidence of the greater or less extent to which famine prevailed in that year. This does not apply, however, to either Assam or Coorg, in both of which cases the high mortality was caused by the exceptional prevalence of fever. The low fever-rate in Madras is undoubtedly due to a difference of classification:—

Province.	Ratio of Deaths per 1000 of Population, 1897.						
	Cholera.	Smallpox.	Fever.	Dysentery.	Injuries.	All other Causes.	Total.
Bengal	2·76	0·27	23·62	0·75	0·59	4·92	32·91

(J. S. Co.)

Recent History.

The period dealt with in this article is mainly comprised in the interval between the years 1880 and 1900. Roughly speaking, of the years from the close of 1858, when the government of British India was transferred from the East India Company to the Crown, to the commencement of 1900, half were occupied in preparing, in plotting out, and in making a vigorous commencement in the execution of the great projects for the moral and material development of India, of which the latter half saw the application and extension. The schemes which were then put into force, more particularly for the material development of India, for increasing the system of railway communications, for fiscal reform, or for the prosecution of irrigation works, had their inception in the preceding period, and more particularly in its second decade. The work of reorganization, of progress, and of financial reform, which was commenced in 1859 by Lord Canning, though from time to time hindered under his successors by war, was on the whole continuously carried on. In spite of discouragement from famines and plague, from a succession of wars on the north-western and eastern frontiers, and from the ruinous effect on Indian finance of the continuous fall in the value of silver relatively to gold, the work begun in the first half of the forty-one years under review, and vigorously resumed after 1880, was more or less consistently carried on up to 1900. Thus the whole period forms, as it were, one growth. The first half is inextricably bound up with the second; and while much of the progress of the last twenty years has been in directions previously but little pursued, more has been but the sequence and necessary outcome of the foregoing period. It is therefore desirable to review the position in which the Government, in some at least of its more important branches, found itself at the close of 1879. With the military and political departments of the Government this article is only so far concerned as may be necessary to show their bearing on finance or polity.

The Position in 1880.

The finances of the country, which, during the years immediately preceding 1876 and 1877, had been very carefully husbanded by the Indian Government, were in those two years made the subject of a fresh and exhaustive study. Sir John Strachey took charge of the finances in 1876, and his administration marks a new era in Indian finance. He was not destined to reap the fruit of all his labours; but great changes had already been effected by him, and more were in contemplation, when the stress and strain of the Afghan war deferred their execution. The obstructive old internal salt customs frontier line, stretching at one time from the Indus to the Mahanadi in Madras, a distance of 2300 miles, and guarded by nearly 2000 men, had been finally abolished. The inland salt duties throughout India were at the same time in great measure equalized. In Bengal and in Northern India the duty had been reduced; in Bombay and Madras it had been raised. Arrangements had been concluded with certain native states by which, subject to compensation allotted to them, the great Indian sources of salt supply, which lie for the most part within their territories, were made over to the control of the Government of India. The consumption of salt at once considerably increased as a consequence of this measure, and the revenue corresponded. For the whole of India the average annual consumption rose from 24,424,000 maunds in 1875–77 to 27,550,000 maunds in 1879–81, the revenue increasing at the same time from £5,996,000 to £6,834,000.[1] Similar reforms had been contemplated, and in a small measure had been commenced, with regard to the customs revenue from import duties levied in India on cotton goods. In July 1877 the House of Commons resolved that the import duties levied in India on cotton goods were protective in their nature, and should be repealed as soon as the condition of India should permit. In 1878 the cotton duties were slightly diminished, and some other reductions were made at a cost to the revenue of £77,000. In 1879 the cotton

Finance.

[1] Throughout this article, unless otherwise indicated, the pound sterling is taken to represent ten rupees, being the "conventional sterling," or "Rx," of Indian accounts, till a recent date.

duties were further reduced at a cost of £200,000, but larger remissions were prevented owing to the effect on the finances of military operations in Afghanistan.

During Lord Mayo's rule administrative measures had been initiated, having for their object the decentralization of the finances; the transfer, that is to say, to the several provincial governments of the direct control of a portion of the public receipts and expenditure within their limits, with corresponding relief and advantage to the central administration. In 1877–79 these measures were further developed. Certain important local sources of revenue were definitely placed in the hands of the provincial governments, which were left to cultivate and improve them, to augment their produce, and to spend all or a definite part of them, at their discretion. On the other hand, the expenditure in certain branches of administration was transferred to provincial governments, of which the cost would be defrayed from the funds assigned them. Economy and good administration resulted, so far as the finances and the provincial governments were concerned, while the central government was relieved from provincial importunities, of which it could not always measure the relative importance, and from the control of details of provincial administration of which, in truth, it was not a competent judge.

Decentralization.

During the twenty-one years preceding 1880 both Upper and Southern India had been visited at times by devastating famines. The Madras famine of 1877–78 greatly exceeded in severity any which had of late years preceded it, and led to the appointment in January 1878 of a very carefully selected commission, presided over by General Strachey, R.E., to advise and report on measures which might palliate the effects of such calamities in future. In 1880 they presented their report, dealing exhaustively with all aspects of the question. Chief among the subjects handled by them was the extension of railway construction. In 1878 the length of guaranteed broad gauge lines was about 6000 miles, being the fruit of twenty-eight years' construction. On the state railways, at the same date in the nine previous years, 1050 miles of broad gauge and 1200 miles of narrow gauge had been completed; in all, say, 8250 miles. The Government of Lord Mayo had, not long before, inaugurated, in lieu of the costly method of guaranteed railways heretofore in force, the system of construction of state railways by loans, supplemented by such funds as could be annually spared from revenue. The famine commission estimated the length of railway which would be needful to ensure the ends they proposed at 20,000 miles. "Until the whole country," they wrote, "is more completely supplied with railways or canals by which food can be transported cheaply and in large quantities to every part where severe want may exist, the possibility of some unusual demand for Government interference in particular localities, or for special classes of people, cannot be shut out, nor the danger of the occurrence of a great calamity altogether removed. It is therefore to the improvement of the internal communications, and the removal of all obstructions to the free course of trade, accompanied by the extension of irrigation in suitable localities, and an improved agriculture, that we look for obtaining security against disastrous failures of the food supply in tracts visited by droughts." Though the scheme then put forward has been modified and added to in course of time, the views and estimate of railway requirements thus enunciated by the famine commission have formed a standard which has uniformly guided the Government of India from 1880 to the present day. Similarly, after an elaborate review of the extent of irrigation from public works, the commission had advocated for the needs of each province a large extension of the then existing system. The area under artificial irrigation in 1878 is given in the Report of the Indian Famine Commission of 1898 at 5,171,497 acres from productive works (p. 338).

Famine and railway policy.

After the famine of 1874 in Bengal Lord Northbrook had declared that to enable the state to meet the obligation of preventing and relieving famine, it was necessary to secure, in prosperous times, a substantial surplus of revenue over expenditure, in addition to that needful margin which a prudent Administration always requires for the ordinary service of the state. Due provision would thus be made for meeting occasional expenditure on famine. Taking an average of years, it was subsequently estimated that the annual cost of relieving famine, including loss of revenue and actual expenditure, would not be likely to exceed £1,500,000. As in 1877 the Government believed that the ordinary income and expenditure of the state might be considered to be for practical purposes in a state of equilibrium, it was believed necessary to improve the financial position by £1,500,000 a year on account of famine liabilities alone, and in addition to this to provide a margin on the annual estimates of at least £500,000, to meet unforeseen contingencies. A considerable portion of this £2,000,000 was supplied by a transfer of charges to provincial governments under the decentralization scheme above referred to; the rest was provided by fresh taxation. New taxation on land by means of rates imposed in Bengal, the North-West Provinces, Oudh, and the Central Provinces, provided about £525,000. Imposition of a license tax on trades and professions throughout India yielded about £820,000—in all £1,345,000. This was the total amount of famine insurance taxation then imposed. The money thus obtained, or so much of the one and a half million as remained after meeting charges for famine during any current year, was to be applied to the discharge of debt, or the prosecution of remunerative public works of a character likely to give protection to the country against the effects of drought, that is to say, to construction of railways or irrigation works. But in years of deficit the grant was necessarily suspended, and the fiscal sources from which it was drawn were in part or in whole diverted to meet the requirements of ordinary expenditure.

Famine insurance.

Education had advanced during the twenty years under review, though relatively to area and population it was still in an extremely backward state. A despatch from England in 1854 had laid down with fulness and precision the principles which were to guide the Government in state education, and its provisions were continued and enlarged by a subsequent despatch of 1859. These two despatches still form the charter of education in India. In 1859 there are believed to have been but little over 50,000 schools, including indigenous schools, and 925,000 scholars for all India, of whom more than 500,000 were pupils of indigenous schools. In 1881–82 there were 112,632 schools, including those for Europeans and Eurasians and for special instruction, with 2,665,636 pupils. The average throughout British India (exclusive of British Burma), according to the census of 1881, was one male under instruction to 42 of the whole male population, and one female to 858 of the whole female population. This may be contrasted with the rule in European countries, where it is usual to take the children of school-going age as one-sixth of the entire population, so that, in round numbers, one child would be at school for every six persons of the population. A large extension of primary education was therefore urgent, and in all

Education.

respects progress had been extremely slow. The three universities of Calcutta, Madras, and Bombay had been incorporated in 1857 by Acts of the Indian legislature. Among the several presidencies and provinces Bengal and Madras had on the whole shown the greatest advance; but Bombay, with its large and highly intelligent Parsee population, has always been prominent in respect of education.

The three great codes which pre-eminently do honour to the Indian legislature—the Penal Code, the Code of Criminal Procedure, and the Civil Procedure Code—were passed during the earlier part of the sixth decade of the 19th century. The labours of Sir Henry Sumner Maine and Sir FitzJames Stephen had enriched the Indian statute-book with other important Acts, such as the Evidence Act, various forest laws, the Criminal Tribes Act, the Christian Marriage Act, the Mahommedan and Parsee Marriage Act, and an Act for the Prevention of the Murder of Female Infants. The relations of landlord and tenant in Upper India and in Oudh had occupied the attention of the legislature. A high court of judicature, similar to those already existing in Calcutta, Bombay, and Madras, had been established for the North-West Provinces. The police system throughout India had been reorganized; sanitation had been especially recognized as claiming attention; the trade of India had developed from a total in round figures of 41 millions of imports and 43 millions of exports in 1859–64 to a total of 62 millions of imports and 76 millions of exports in 1880–81. Notably the great tea industry had taken firm root, and was assuming ever-increasing proportions. In 1879 there were 58 mills in India for the manufacture of cotton yarn and cloth by steam machinery. They worked 1½ million spindles and 1200 looms, giving employment to upwards of 40,000 persons. Of this total 44 mills were in the island or province of Bombay, 6 in Calcutta, 3 in Madras, the rest in various localities. There existed at that date 21 jute mills, mostly in Bengal. Brewing had been introduced, and was becoming more and more extended. Steam paper mills and some minor industries had also taken root.

Social progress.

During little less than half of the twenty-one years of the period with which we are dealing the Government of India had been in the hands of Lord Lawrence and Lord Northbrook. Both were pre-eminently men of caution, and in questions of Indian administration both were highly conservative. Their policy in home matters was to exercise extreme reserve in increasing fiscal burdens, and in foreign matters to abstain rigorously from interference beyond their borders. During their tenure of office, Lord Canning, Lord Elgin, and, on the whole, Lord Mayo, shared these characteristics. The administrative note, therefore, of the seventeen years from 1859, after the close of the Mutiny, to 1876 was one of moderation and cautious advance. They were years but little removed from the rule of the late East India Company and the great catastrophe of 1857. The whole machinery of Government, more especially during the earlier part of that period, was successively brought under review, and in almost every department reorganization more or less complete was projected. It was a time mainly of study and deliberation, preliminary to action; of prudent but thorough overhauling of the administration which had been but recently handed over to the Crown. The educational and other civilizing influences which had been established for the first time in years little anterior to 1859 had scarcely begun to make themselves felt. The population in almost every grade and class was still intimidated, inert, and irresponsive. In the latter half of the seventh decade of the century, however, the confidence and experience gained in previous years were beginning to bear fruit.

Administrative policy.

Such was the position on the eve of the period about to be dealt with. The revenues were in a sound condition; the country was quiet and content; time and scrutiny had suggested reform, for which the moment was now ripe; a generation had grown up in tranquillity since the horrors of 1857. Suddenly the Afghan war of 1878 broke out. For two years the whole resources of the Administration were strained to bring the struggle to a successful issue. The progress of the country was paralysed and the reform of its finances arrested. Nor was it till the close of that war, and the departure of Lord Lytton from the scene in 1880, that work was resumed and effect was given to financial and other reforms, for which the labours of the administration and the lapse of time had now prepared the country.

Summary 1860-1880.

Many eminent men had taken part in the government of India during the period from 1859 to 1880. But in any sketch of that period it should be recorded that among those who assisted successive Viceroys with their advice and experience India owes unquestionably the most to Sir Richard and Sir John Strachey. Each of these distinguished brothers, in one or other capacity, successively held high and important offices in the state from 1864 to 1880. The former belonged to that illustrious corps of Bengal (now Royal) Engineers, which has given so many brilliant men to civil and political administration in India; the latter to the Indian Civil Service. In their joint volume, *The Finances and Public Works of India, from 1869 to 1881*, they have left an invaluable record of the principal administrative measures which they initiated or in which they actively participated.

From 1880 *to* 1901.

With the advent in 1880 of Lord Ripon as Viceroy the portals of war were closed, and India entered once more upon the pleasant paths of peace. Remission of taxation, encouragement of primary and secondary education, the promotion of local self-government, the amelioration of the status of the agricultural tenant, the recognition and promotion of native claims to a share in directing the internal affairs of India—these were the cardinal points of the policy of 1880 and the years immediately ensuing. During the preceding period the attention of the central government, and the genius of those who inspired it, had been more immediately devoted to the material progress of India. Of that sympathetic and indulgent handling of the native population which characterized the East India Company, the traces become less and less apparent as we pass from the sixth towards the close of the seventh decade. The greatest benefits had been conferred on the people by the fiscal and public works measures introduced during those years. But of any seeking or strengthening of personal touch with them on the part of the Administration there is comparatively little trace. Much was done for the people, but in concert with them little was attempted. The steps taken in this direction during the eighth decade mark a return to the more personal and human aspects of administration which before 1857 had been perhaps exclusively prominent, but which of later years might be judged to have fallen too greatly into abeyance. In short, after 1880, and for a brief term of subsequent years, the moral development of India again took an equal place in the foreground, and the characteristic note of the decade which succeeded 1880 is to be found in the greater effort made during that period to combine moral with material progress.

duties were further reduced at a cost of £200,000, but larger remissions were prevented owing to the effect on the finances of military operations in Afghanistan.

During Lord Mayo's rule administrative measures had been initiated, having for their object the decentralization of the finances; the transfer, that is to say, to the several provincial governments of the direct control of a portion of the public receipts and expenditure within their limits, with corresponding relief and advantage to the central administration. In 1877–79 these measures were further developed. Certain important local sources of revenue were definitely placed in the hands of the provincial governments, which were left to cultivate and improve them, to augment their produce, and to spend all or a definite part of them, at their discretion. On the other hand, the expenditure in certain branches of administration was transferred to provincial governments, of which the cost would be defrayed from the funds assigned them. Economy and good administration resulted, so far as the finances and the provincial governments were concerned, while the central government was relieved from provincial importunities, of which it could not always measure the relative importance, and from the control of details of provincial administration of which, in truth, it was not a competent judge.

Decentralization.

During the twenty-one years preceding 1880 both Upper and Southern India had been visited at times by devastating famines. The Madras famine of 1877–78 greatly exceeded in severity any which had of late years preceded it, and led to the appointment in January 1878 of a very carefully selected commission, presided over by General Strachey, R.E., to advise and report on measures which might palliate the effects of such calamities in future. In 1880 they presented their report, dealing exhaustively with all aspects of the question. Chief among the subjects handled by them was the extension of railway construction. In 1878 the length of guaranteed broad gauge lines was about 6000 miles, being the fruit of twenty-eight years' construction. On the state railways, at the same date in the nine previous years, 1050 miles of broad gauge and 1200 miles of narrow gauge had been completed; in all, say, 8250 miles. The Government of Lord Mayo had, not long before, inaugurated, in lieu of the costly method of guaranteed railways heretofore in force, the system of construction of state railways by loans, supplemented by such funds as could be annually spared from revenue. The famine commission estimated the length of railway which would be needful to ensure the ends they proposed at 20,000 miles. "Until the whole country," they wrote, "is more completely supplied with railways or canals by which food can be transported cheaply and in large quantities to every part where severe want may exist, the possibility of some unusual demand for Government interference in particular localities, or for special classes of people, cannot be shut out, nor the danger of the occurrence of a great calamity altogether removed. It is therefore to the improvement of the internal communications, and the removal of all obstructions to the free course of trade, accompanied by the extension of irrigation in suitable localities, and an improved agriculture, that we look for obtaining security against disastrous failures of the food supply in tracts visited by droughts." Though the scheme then put forward has been modified and added to in course of time, the views and estimate of railway requirements thus enunciated by the famine commission have formed a standard which has uniformly guided the Government of India from 1880 to the present day. Similarly, after an elaborate review of the extent of irrigation from public works, the commission had advocated for the needs of each province a large extension of the then existing system. The area under artificial irrigation in 1878 is given in the Report of the Indian Famine Commission of 1898 at 5,171,497 acres from productive works (p. 338).

Famine and railway policy.

After the famine of 1874 in Bengal Lord Northbrook had declared that to enable the state to meet the obligation of preventing and relieving famine, it was necessary to secure, in prosperous times, a substantial surplus of revenue over expenditure, in addition to that needful margin which a prudent Administration always requires for the ordinary service of the state. Due provision would thus be made for meeting occasional expenditure on famine. Taking an average of years, it was subsequently estimated that the annual cost of relieving famine, including loss of revenue and actual expenditure, would not be likely to exceed £1,500,000. As in 1877 the Government believed that the ordinary income and expenditure of the state might be considered to be for practical purposes in a state of equilibrium, it was believed necessary to improve the financial position by £1,500,000 a year on account of famine liabilities alone, and in addition to this to provide a margin on the annual estimates of at least £500,000, to meet unforeseen contingencies. A considerable portion of this £2,000,000 was supplied by a transfer of charges to provincial governments under the decentralization scheme above referred to; the rest was provided by fresh taxation. New taxation on land by means of rates imposed in Bengal, the North-West Provinces, Oudh, and the Central Provinces, provided about £525,000. Imposition of a license tax on trades and professions throughout India yielded about £820,000—in all £1,345,000. This was the total amount of famine insurance taxation then imposed. The money thus obtained, or so much of the one and a half million as remained after meeting charges for famine during any current year, was to be applied to the discharge of debt, or the prosecution of remunerative public works of a character likely to give protection to the country against the effects of drought, that is to say, to construction of railways or irrigation works. But in years of deficit the grant was necessarily suspended, and the fiscal sources from which it was drawn were in part or in whole diverted to meet the requirements of ordinary expenditure.

Famine insurance.

Education had advanced during the twenty years under review, though relatively to area and population it was still in an extremely backward state. A despatch from England in 1854 had laid down with fulness and precision the principles which were to guide the Government in state education, and its provisions were continued and enlarged by a subsequent despatch of 1859. These two despatches still form the charter of education in India. In 1859 there are believed to have been but little over 50,000 schools, including indigenous schools, and 925,000 scholars for all India, of whom more than 500,000 were pupils of indigenous schools. In 1881–82 there were 112,632 schools, including those for Europeans and Eurasians and for special instruction, with 2,665,636 pupils. The average throughout British India (exclusive of British Burma), according to the census of 1881, was one male under instruction to 42 of the whole male population, and one female to 858 of the whole female population. This may be contrasted with the rule in European countries, where it is usual to take the children of school-going age as one-sixth of the entire population, so that, in round numbers, one child would be at school for every six persons of the population. A large extension of primary education was therefore urgent, and in all

Education.

respects progress had been extremely slow. The three universities of Calcutta, Madras, and Bombay had been incorporated in 1857 by Acts of the Indian legislature. Among the several presidencies and provinces Bengal and Madras had on the whole shown the greatest advance; but Bombay, with its large and highly intelligent Parsee population, has always been prominent in respect of education.

The three great codes which pre-eminently do honour to the Indian legislature—the Penal Code, the Code of Criminal Procedure, and the Civil Procedure Code—were passed during the earlier part of the sixth decade of the 19th century. The labours of Sir Henry Sumner Maine and Sir FitzJames Stephen had enriched the Indian statute-book with other important Acts, such as the Evidence Act, various forest laws, the Criminal Tribes Act, the Christian Marriage Act, the Mahommedan and Parsee Marriage Act, and an Act for the Prevention of the Murder of Female Infants. The relations of landlord and tenant in Upper India and in Oudh had occupied the attention of the legislature. A high court of judicature, similar to those already existing in Calcutta, Bombay, and Madras, had been established for the North-West Provinces. The police system throughout India had been reorganized; sanitation had been especially recognized as claiming attention; the trade of India had developed from a total in round figures of 41 millions of imports and 43 millions of exports in 1859–64 to a total of 62 millions of imports and 76 millions of exports in 1880–81. Notably the great tea industry had taken firm root, and was assuming ever-increasing proportions. In 1879 there were 58 mills in India for the manufacture of cotton yarn and cloth by steam machinery. They worked $1\frac{1}{2}$ million spindles and 1200 looms, giving employment to upwards of 40,000 persons. Of this total 44 mills were in the island or province of Bombay, 6 in Calcutta, 3 in Madras, the rest in various localities. There existed at that date 21 jute mills, mostly in Bengal. Brewing had been introduced, and was becoming more and more extended. Steam paper mills and some minor industries had also taken root.

Social progress.

During little less than half of the twenty-one years of the period with which we are dealing the Government of India had been in the hands of Lord Lawrence and Lord Northbrook. Both were pre-eminently men of caution, and in questions of Indian administration both were highly conservative. Their policy in home matters was to exercise extreme reserve in increasing fiscal burdens, and in foreign matters to abstain rigorously from interference beyond their borders. During their tenure of office, Lord Canning, Lord Elgin, and, on the whole, Lord Mayo, shared these characteristics. The administrative note, therefore, of the seventeen years from 1859, after the close of the Mutiny, to 1876 was one of moderation and cautious advance. They were years but little removed from the rule of the late East India Company and the great catastrophe of 1857. The whole machinery of Government, more especially during the earlier part of that period, was successively brought under review, and in almost every department reorganization more or less complete was projected. It was a time mainly of study and deliberation, preliminary to action; of prudent but thorough overhauling of the administration which had been but recently handed over to the Crown. The educational and other civilizing influences which had been established for the first time in years little anterior to 1859 had scarcely begun to make themselves felt. The population in almost every grade and class was still intimidated, inert, and irresponsive. In the latter half of the seventh decade of the century, however, the confidence and experience gained in previous years were beginning to bear fruit.

Administrative policy.

Such was the position on the eve of the period about to be dealt with. The revenues were in a sound condition; the country was quiet and content; time and scrutiny had suggested reform, for which the moment was now ripe; a generation had grown up in tranquillity since the horrors of 1857. Suddenly the Afghan war of 1878 broke out. For two years the whole resources of the Administration were strained to bring the struggle to a successful issue. The progress of the country was paralysed and the reform of its finances arrested. Nor was it till the close of that war, and the departure of Lord Lytton from the scene in 1880, that work was resumed and effect was given to financial and other reforms, for which the labours of the administration and the lapse of time had now prepared the country.

Summary 1860-1880.

Many eminent men had taken part in the government of India during the period from 1859 to 1880. But in any sketch of that period it should be recorded that among those who assisted successive Viceroys with their advice and experience India owes unquestionably the most to Sir Richard and Sir John Strachey. Each of these distinguished brothers, in one or other capacity, successively held high and important offices in the state from 1864 to 1880. The former belonged to that illustrious corps of Bengal (now Royal) Engineers, which has given so many brilliant men to civil and political administration in India; the latter to the Indian Civil Service. In their joint volume, *The Finances and Public Works of India, from 1869 to 1881*, they have left an invaluable record of the principal administrative measures which they initiated or in which they actively participated.

From 1880 *to* 1901.

With the advent in 1880 of Lord Ripon as Viceroy the portals of war were closed, and India entered once more upon the pleasant paths of peace. Remission of taxation, encouragement of primary and secondary education, the promotion of local self-government, the amelioration of the status of the agricultural tenant, the recognition and promotion of native claims to a share in directing the internal affairs of India—these were the cardinal points of the policy of 1880 and the years immediately ensuing. During the preceding period the attention of the central government, and the genius of those who inspired it, had been more immediately devoted to the material progress of India. Of that sympathetic and indulgent handling of the native population which characterized the East India Company, the traces become less and less apparent as we pass from the sixth towards the close of the seventh decade. The greatest benefits had been conferred on the people by the fiscal and public works measures introduced during those years. But of any seeking or strengthening of personal touch with them on the part of the Administration there is comparatively little trace. Much was done for the people, but in concert with them little was attempted. The steps taken in this direction during the eighth decade mark a return to the more personal and human aspects of administration which before 1857 had been perhaps exclusively prominent, but which of later years might be judged to have fallen too greatly into abeyance. In short, after 1880, and for a brief term of subsequent years, the moral development of India again took an equal place in the foreground, and the characteristic note of the decade which succeeded 1880 is to be found in the greater effort made during that period to combine moral with material progress.

When introducing the budget of 1882–83 the financial member of the Viceroy's council was able to announce that the surplus in the preceding year amounted to £1,577,000; the revenue having been £72,913,000, the expenditure £71,336,000. The flourishing condition of the finances, he hastened to point out, so far as it resulted from financial administration, was due, not to the Government existing at that time, but to its predecessor. In point of fact, but for certain readjustments and repayments to provincial governments of sums borrowed from them during the late years, the surplus would have been very much larger, and the sum of £1,577,000 fell far short of the amount by which the normal revenue of the year was estimated to exceed the normal expenditure. It has been explained how, by skilful management of the finances, this surplus had been prepared. To Sir Evelyn Baring (afterwards Lord Cromer) fell the pleasant labour of reaping where Sir John Strachey had sown. The remission of import duties, more particularly of import duties on cotton goods, which had been the object of the latter, and which had been in a small measure enforced by him, was carried by the former into full effect. The remaining cotton duties were abolished, involving a reduction of taxation of £655,000, while at the same time the whole of the general tariff of 5 per cent. *ad valorem* was abandoned, at a net cost (including the cotton duties) of £1,109,000. Thus in 1882 India was freed from taxation on her imports, strong liquors and salt excepted. The customs duty thenceforth, and till further changes, was derived entirely from the produce of an export duty on rice, and from import duties on salt and alcohol. At the same time the salt duty was reduced from a general rate of Rs.2/8 to Rs.2 per maund. The estimated loss of revenue consequent on this reduction was £1,400,000. A total of 2½ millions in taxation was thus remitted to the country. In the light of subsequent events it is necessary and important to record some of the remarks with which Sir Evelyn Baring accompanied the reductions thus effected: "As an incident of her connexion with England, India," he said, "has a right to benefit from English experience and English economic history. That experience and that history show that by the adoption of free trade a country benefits, indeed, all the world, but more especially benefits itself. . . . By the adoption of the measures now proposed India will be more free to exchange her exportable produce for the products of foreign lands than would be possible were the import duties maintained. . . . In addition to the general arguments, which would readily admit of further development, there is one consideration which applies especially to India, and which, I venture to think, is at the present moment of considerable importance. The desirability of rapidly extending our railway system is universally recognized. The main obstacle to any such rapid extension is the difficulty of attracting railway capital to India on terms that shall not be too onerous to the state. No fiscal measure of general application would be so likely to give a stimulus to railway construction as the removal of all restrictions on trade." In their *Finances and Public Works of India* (p. 295) the two Stracheys, writing in 1881, had expressed themselves on the subject in stronger terms: "The policy followed by the Government of India during the viceroyalty of Lord Lytton was one of absolute free trade, without reserve or qualification, and financial necessities alone prevented that policy from being carried out to the fullest extent. The proceedings of the last three or four years have, however, succeeded in rendering inevitable the almost total abolition of the customs duties, which of all Indian taxes are probably the worst." In the debate on his financial statement for 1880–81 Sir John Strachey had said: "I hardly remember the time when I did not argue in the interests of India for the removal of these and all other restrictions on commerce. . . . I would not have accepted my present office if I had not hoped that I should have an opportunity of co-operating with your Excellency in carrying out what I may say without exaggeration have been the convictions of a lifetime" (*op. cit.*, p. 311).

Financial policy.

Tariff reform.

As to the reduction in the salt duty from Rs.2/8 to Rs.2 per maund, we read in the financial statement for 1882–83: "The advantages to be gained by a reduction of the salt duty are twofold. In the first place, it is exceedingly desirable to reduce the price of a necessary of life which is used by the poorest classes. In the second place, the financial situation will be much strengthened." It was explained in subsequent words that, "If any unforeseen circumstance, such as a heavy fall in the value of silver, takes place, and if at the same time the reduction in the salt duty does not result in any considerable increase in the consumption of salt, it would be open to us to return temporarily to a higher rate." The Stracheys had pointed out that if the policy of maintaining a low and uniform rate of duty on salt were followed for some years to come, the average consumption would increase throughout India, and the revenue would become several millions larger. The Government would thus have in its hands a powerful reserve of taxation. "But these results will only be obtained if we steadily persevere in the course that has lately been followed. We must finally abandon the erroneous notion that it is profitable to levy the salt tax at a high rate on a restricted consumption, and resolve to act at all times on the only sound principle, that the interests of the people and of the public revenue are identical; for we shall receive the largest possible revenue when the salt duties are low, and when the people throughout India obtain an unlimited supply of salt at the cheapest possible cost" (*op. cit.*, 233–34).

When we review the subsequent history of finance in India, we shall learn what has been the fate of the reforms introduced in 1882–83. We may then recall to mind the opinions formed in regard to the cotton and salt duties by two of the most competent men who have directed the finances of India. It is, however, necessary to add that the abolition of the import duties on cotton goods was carried out against the very general feeling whether of Europeans or of the educated natives of India. Sir Evelyn Baring, in his financial statement of 1882–83, referred in the following terms to this aspect of the matter:—"Before leaving this subject, I may perhaps be permitted to express the hope that the solution which the Government now offers of this difficult and important problem will be accepted by this council, and by the public opinion of England and India, as satisfactory, and that it will finally set at rest the angry controversy that has for some years been waged. That controversy has unfortunately taken a form which no true friend of England or of India can view without regret. It has been represented, erroneously, as I venture to think, that in respect to the question now under discussion there is an antagonism of interests between the two countries." It is remarkable that when the first step was taken in 1879 of remitting the duties on all grey goods consisting of yarns finer than 30s, it was adopted by Lord Lytton in opposition to the majority of his council. One of the dissentient members stated that there were not a dozen officials in India who did not regard the policy as having been taken in the supposed interests of a political party

The political issue.

in England, the leaders of which deemed it necessary at any cost to retain the political support of the cotton manufacturers in Lancashire. The Stracheys admit that, making allowance for some exaggeration of expression, this statement doubtless contained a good deal of truth as to the state of public opinion (*Finances and Public Works of India*, p. 287). A striking illustration is to be found in pages where we should have scarcely looked for it. In the latest edition of his *Indian Polity* (1894) we find an Indian official of distinction, the late Lieut.-General Sir George Chesney, committing himself to the following expression of views which, in substance and in warmth of expression, recall twelve years later the angry controversy of the year preceding 1882:—"One source of revenue, free from the objections apparent to every other form of import, is to be found in the restoration of the cotton duties. The history of this case is still so fresh in recollection that it is not necessary to recapitulate it. That the tax has not yet been re-imposed is due, not to any consideration for the people of India, but simply to the supposed exigencies of party government at home. The principle involved, however, goes far beyond one of pure finance. It opens up the larger question, whether the Government of India is to be conducted in sympathy with the interests and feelings of the people of the country, or in accordance with the small and shifting policy of party needs; as to which it may be said that, unless the steps lately taken are retraced, an injury will be done to the good faith and character of the British Government of India, which may and probably will lead to far-reaching consequences" (*Indian Polity*, p. 347).

In this matter we may well be guided by the opinion of highly competent Indian financiers like Sir John Strachey and Sir Evelyn Baring, who had devoted to the subject prolonged and anxious inquiry. Nor should undue weight be attached to the *dictum* of a critic who, though deeply versed in military questions, had enjoyed no opportunities of personally handling many of the fiscal or administrative problems, the merits or demerits of which are pronounced upon in his pages.

The salaries of the upper grades of the native subordinate executive services were improved in 1882, at an estimated increase of about £50,000 a year. It was declared to be the intention of the British Government and of the Government of India that a constantly increasing share of the work of the country should be performed by natives of India. Figures showed that of 4082 officials employed in these branches of the public service which are directly engaged in the internal administration of the country, as apart from those employed in special branches (such as the post office or telegraph), 2058 were Europeans and 2024 were natives. In the upper or "covenanted" service, 861 were of the former and 12 only of the latter class. In the subordinate service 1197 were Europeans and 2012 were natives. This question of the employment of qualified natives, and of their advancement to higher grades of employment, is one ever present to the mind of the Indian Government, but beset by the greatest difficulties. Few aspects of Indian administration are more disagreeable at first sight than this, that with few exceptions all the higher posts, which carry with them the larger salaries, are confined to Europeans. Given the conditions and requirements of the administration, this is at present inevitable. But it necessarily bears on the face of it that appearance of a monopoly by a foreign caste of the higher grades of employment, which cannot fail to attract hostile criticism. It may confidently be asserted on behalf of the Indian Government, that it is ever on the watch to modify the existing state of matters, and is more than desirous of finding occasion for the advancement of natives to the higher ranks of civil employ. Its efforts in this direction have not been rewarded, so far, with any corresponding success. But it will be seen that at a somewhat later date than that with which we are dealing the subject was comprehensively considered by the Government of Lord Dufferin. A fresh basis was then established, on which rest the present rules and regulations by which are governed the admission and advancement of natives into the higher service. Any native now who, by education, force of character, probity, or good service, can prove his fitness for advancement to the higher grades of employment is no longer debarred from arriving at them.

Employment of natives in public service.

The system of decentralization, and of assigning to provincial governments the financial profit and loss on certain branches of administration, was largely extended in 1882. Practically, excepting the departments of army, marine, post office, telegraphs, opium, salt, customs, and for the most part the railways, all branches of the public service, with their receipts and expenditure, may be said to have been then made over to provincial hands. The result has been productive of economy and of good government; but on the other hand the measure has erected something of a barrier between the central government and the internal conduct of affairs. Though the central government retains the supreme authority, and regularly exercises its power of general control, it is now exclusively the business of the several provincial authorities, subject to such occasional check, to see to the practical working of the great machine of home administration. It is certain that none but provincial authorities are in close enough contact with local needs, or well informed enough in regard to them, to be prudently charged with the task. But there is reason to fear that by this strengthening of provincial agency the central government has somewhat lost the advantage of the more direct connexion which previously existed between itself and the masses. To borrow a term from telegraphy, there is a fault in communication. The comparative leisure thus gained by the Viceroy and his council has been perhaps the more often turned in later years from the internal requirements of India to military matters, and to territories beyond the Indian frontier. Opinions differ as to whether this need be regarded as a disadvantage. But of the fact there seems little room for question.

Local Government.

In connexion with the extension of provincial finance, greater latitude of self-administration was at the same time accorded to municipalities and local bodies throughout India. Few measures that have been greeted on their introduction with comparative indifference are likely, with lapse of time, to take deeper root in the country than the scheme of conferring self-government on municipalities. The aim and ideal of the energetic and highly-trained officers to whom is entrusted the administration of the various districts into which India for executive purposes is divided, has been hitherto government of and for the people, rather than government by or with the people. The prestige of the powerful Indian civil service is based on successes achieved in past years, when the authority of its officers was the only authority, and when, by the energetic and enlightened exercise thereof, great results had been everywhere obtained. Intimate knowledge of native character, and daily experience of the weaknesses, the jealousies, the animosities, and the trivial aims and pursuits of native society, might well make those who up to the present had been its guides not a little sceptical as to the uses to which local self-government would be put, and doubtful as to the

Municipal progress.

intelligence and interest with which it would be carried into effect. So far as concerns the district or local bodies, these apprehensions have not been without justification. But so far as town and municipal bodies are concerned, the measure of 1882 has met with a degree of success fully equal to any that its authors could have expected. Local self-government in all countries is a plant of slow growth. In India, with its counter-currents of Hindu and Mahommedan, its apathy, its passion for hereditary usages and employment, the indifference of its several units to the general good, the aptitude of the Indian for verbal controversy and inaptitude for collective action, any marked or early development of disinterested public spirit could not be counted on. It would be untrue to assert that the results have so far brought India into line with even moderately progressive European countries. But with regard, at least, to the more important towns, it may be affirmed that the measure enforced by the Government of Lord Ripon has, up to the present time, proved as useful as its authors hoped, and promises with the progress of years to acquire increasing stability. The spirit in which the measure was introduced augured well for its success. The desire was not to force upon all parts of the country a uniform system, but to secure the gradual training of the best, the most intelligent, and most influential men in the community to take an interest and an active part in the management of their local affairs. It was regarded by its promoters as being desirable, less for improvement in administration than as an instrument of political or popular education. The principle of election was introduced under very careful restrictions. Great latitude was left to provincial governments in devising the system best adapted to their several local circumstances. Considerable control was retained over the exercise of the powers to be entrusted to the newly created municipalities.

Reviewing in 1896 the working of the measures introduced fourteen years previously, the Government of India recorded its satisfaction at the marked advance disclosed, and at the activity, intelligence, and general economy with which municipal bodies had improved the conservancy services—the water supply, the drainage, the street paving, the lighting, and the many conveniences of the towns in their charge. At that date, apart from Presidency towns, Rangoon, and Upper Burma, 733 municipalities existed, as against 797 in 1881–82. It was not the number but the composition of municipalities, the mode of nomination by election, the powers conferred on them, and the revenues levied and expended by them, which marked the progress made. Before 1882 municipalities had existed. But they had existed mainly for purposes of local rating, and the consequent relief to the general revenues, enjoying little or no exercise of self-administration. In 1886–87 the total income of all municipalities had amounted to £5,077,754; in 1897–98 it reached the figure of £6,340,661.

Reviewing similarly and at the same time the working of the local boards created in 1882, the Government of India found that useful work had been done. But it is clear from that review that the several provincial governments wrote without enthusiasm of the public spirit, or the administrative energy exhibited by local boards. The interest shown in the closely populated municipal areas, by townsfolk working within more limited spaces, acquainted, for the most part, with one another, aiming at definite ends, and supplied with sufficient funds, far surpasses that which agricultural magnates or rural leaders of native society in their larger orbits exhibited. These men are for the most part content to look after their own estates or to attend to their professional affairs, leaving, as hitherto, to the British official in charge of their district the initiative and main execution of the measures necessary to local administration.

Provincial difficulties.

It is to be noted that in India, and more especially in Upper India, the Mahommedan element, though considerable, is numerically inferior to the Hindu. The former have thus found themselves, wherever election is the rule of appointment, in danger of being left permanently in a minority. They view with distrust and natural dislike the passing of authority into Hindu hands. Especially is this the case where, as often happens, the hands into which power passes are those of classes of Hindus who, though previously of no consideration, of obscure origin, and socially of less than little weight, are enabled by their familiarity with English, and by their education in British colleges, wholly to manipulate and control the municipal councils. In this direction there will for long exist antagonism between Hindu and Mahommedan. Resentment will smoulder on the one side, and on the other there will be little wish to conciliate. In India such differences do not take the form of party, but are inflamed by the virus of race and of religion, and become the more embittered.

The conduct of education and the control of colleges and schools in India is in the hands of the provincial governments. But in this, as in all other departments, the central government retains the ultimate authority. It has been already noted that the main lines on which the system of education in India is carried on were laid down in 1854 and 1859. Since then, necessarily, progress has been made, and fresh developments have called for further instructions. To the three universities of Calcutta, Madras, and Bombay have been added universities at Lahore and at Allahabad, respectively the headquarters of the Punjab and North-Western Governments. All five universities are entirely independent of the department of public instruction. They are autonomous bodies, with a constitution moulded on that of the University of London. The governing body consists of a chancellor, vice-chancellor, and senate. The senate for the most part acts through an executive committee of its members, termed the syndicate. Degrees are conferred at the annual meeting of convocation. These universities are essentially examining bodies, though the Punjab University is responsible for the management of the Oriental College at Lahore, and takes an active part in the improvement of vernacular literature. The influence of the universities, however, extends beyond the mere sphere of examination. By their power to grant or to refuse affiliation they are able to dominate the entire system of higher education from secondary schools upwards. In many cases the universities have themselves been affiliated to the two English universities of Oxford and Cambridge, so that their students can obtain certain exemptions from residence and examination. The universities are practically self-supporting.

Instruction.

Description of the present state of education in India would here be out of place. It will suffice for present purposes to sketch briefly the outlines of the main advance made since 1880. Some particulars have been given in a preceding page of the results achieved before that date. In 1882 a commission of very carefully selected and competent members was nominated to inquire into and report upon the working of the system in force, whether in primary, secondary, or higher education. It presented, as its report, in the following year a most exhaustive and valuable document, to which the reader must be referred who wishes more thoroughly to acquaint himself with the details of Indian education. Educational institutions in

Educational progress.

India are of two classes. First there are those which conform to the standards prescribed by the department of public instruction or the university, and of which the pupils are examined by one or the other. These are called public institutions, but may be under either public or private management, the latter being mostly known as "aided" schools. These are supported largely by grants in aid from the Government. The second class of institution consists of those which do not fulfil the above conditions, and are called private. The grades of education are found in primary and secondary schools, and in colleges. In the former, reading and writing are taught, and such elementary knowledge as may enable a peasant to look after his own interests. Secondary schools are divided into English and vernacular, the former being those in which the teaching of English occupies a more prominent part. In colleges, the students are those who, having passed the matriculation examination of a university, are reading for the further examinations required for a degree.

The statistics of educational progress are given in the preceding article, and they show that the number of pupils in the colleges and of each class of schools is increasing steadily. Of a direct state expenditure in 1896–97 of £1,198,564 on institutions, 68·5 per cent. was devoted to institutions under public management, and 31·5 per cent. to "aided" institutions, under which class falls the great and important section of missionary schools. The average cost of educating each student was, in the arts Government colleges in 1896–97, Rs.160·3; in professional colleges it reached the highest figure, Rs.196·4. Each educated student in the arts college costs the state Rs.269·9.

Western education at the most has as yet touched little more than the fringe of Indian life. But the crying defect of education in India is the failure to find means of extending education to girls. Only 402,158 girls were under instruction in 1896–97, whether in public or private institutions, forming 2·34 of the percentage of school age. Practically, woman in India is wholly uninfluenced by Western education. Mothers, wives, or daughters at no time of their existence come under its influence. Whether from a social or political point of view this is lamentable, and the consequences are far-reaching and injurious. The influence of women in India is very considerable, and it is to be feared that it is exerted consistently in a direction opposed to the ethical or educational standards set up in English teaching institutions. But the position of woman in the East, and the strictness with which, after her earlier years, she is guarded from contact with all but the nearest members of her family, oppose barriers which are at present impassable. Madras and Bengal show the largest number of girl students (116,747 and 113,767), followed by Bombay (82,163). Upper India contributes comparatively few. Thus in the North-West Provinces and Oudh, ·46 per cent. only of girls of school-going age were under instruction in 1896–97. Even of the small total of 402,158 girls under instruction in all India, a considerable number were native Christians, who are outside the pale of native social life. Another point which may be observed is the comparative backwardness of Mahommedans in attending British schools. Thus in 1896–97, while the proportion of Mahommedans to the total population was 21·81, the percentage of Mahommedans to Hindus and others in primary schools was 20·16, in secondary schools 14·20, in arts colleges 7·00, in professional colleges 6·67. In special schools, being schools either for training masters or mistresses, or for technical teaching, such as art, law, medicine, surveying, handicrafts, &c., the proportion rose to 25·06. It may, however, be noted that among the most conspicuous examples of successful native effort in public interests in India is the Anglo-Mahommedan College at Aligarh in the North-West Provinces, founded some years ago by the late Sir Sayad Ahmad Khan.

The instruction for the most part in Indian colleges and schools is literary, as distinguished from professional or technical. Till late years there has been little demand for the engineer, while the lawyer or civil servant has always found openings awaiting him. With the growth of railways and other public works the demand for technical education will increase, but as yet there is little provision for it. In the quinquennial review from which the foregoing figures have been taken it is said that it must not be inferred that the experiment of giving a more favourable practical turn to education, which was actively started in India about 1890, has proved altogether barren. Though the results may fall short of the anticipation of the more enthusiastic, they are to be seen everywhere, in the more important positions assigned to such practical subjects as agriculture, mensuration, and sanitary science in primary schools, in the rapid spread of drawing, in the popularity of the science side of the ordinary curriculum in both secondary schools and arts colleges, in the institution of alternative courses of examination, as well as in the steady growth of engineering colleges, in the art institutions, and industrial schools. It is therefore with some surprise that we find that the number of engineering colleges in the five years ending 1896–97 has remained, as compared with the previous quinquennial period, at four, and that though the total number of students has risen, it did not at that date exceed 667. There are in all India but 29 engineering schools, and 1393 scholars. It is greatly to be desired that the attendance in the science side of the arts college should increase, and that technical education should expand. The product of the literary side of the Indian arts college is, on the whole, disappointing, and with the growth of time the type does not improve. It varies somewhat in different parts of India, but, though the type more or less obviously is influenced by local conditions, the main characteristics are everywhere identical. It lacks stability, substance, balance of judgment, a sane estimate of its own acquirements. Memory, imagination, dialectic skill, have been fostered by education, rather than observation, exactness, and patient thought. "The fact is," said Sir Henry Maine, in one of his addresses to the University of Calcutta, "that the educated native mind requires hardening. That culture of the imagination, that tenderness for it which may be necessary in the West, is out of place here; for this is a society in which, for centuries upon centuries, the imagination has run riot, and much of the intellectual weakness, and worse evils which afflict it in this moment, may be traced to imagination having so long usurped the place of reason. What the native mind requires is stricter criteria of truth; and I look for the happiest moral and intellectual results from an increased devotion to those sciences by which no tests of truth are accepted except the most rigid."

In general terms it may perhaps be added that, so far as concerns the masses, to live under British administration, when at its best, is in itself a liberal education. Enlightened codes, justice, equality before the law, social and religious freedom, protection, order, method, moderation in the assessment of fiscal burdens, good and easy means of transport, are no mean lessons in enlightenment to the millions who, till comparatively recent years, have lived in the dark ages of bigoted tyranny and have cowered under violence and misrule.

Great attention was paid by Lord Ripon's Government towards carrying out the recommendations of the famine

commission of 1880 with regard to the extension of railways. A programme was prepared in 1883–84 covering the ensuing six years, but it was not put into practical effect till Lord Dufferin had assumed the reins of government in 1885. It is dealt with later in this article. This programme contemplated the construction of 3837 miles of railway, including lines in progress, at a cost of $27\frac{1}{2}$ millions, to be provided partly by the state through revenue and loans, partly through the agency of companies. A select committee of the House of Commons also sat in 1884 to consider the question of railway extension in India. Its report was favourable to the projects of the Government of India, with the reserve that railway extension should not involve additional taxation. It was decided by the Secretary of State, in compliance with the select committee's suggestion, that the annual Indian Public Works Rupee Loan for all public works, whether railways or irrigation, should be raised in future from the amount hitherto sanctioned —viz., $2\frac{1}{2}$ millions—to $3\frac{1}{2}$ millions. Events beyond the north-western frontier, and the consequent urgency with which military railways were pushed on, caused the programme of work to be from time to time materially modified. But from that date to the present time the extension of the Indian railway system, whether directly by the state or by aided enterprise, whether for commercial, protective, or military lines, has been pursued with vigour. From a date but little anterior to 1884 commenced also the important changes which have been made in the system of guarantee, without which, in one or other form, it is rare to find enterprise willing to embark capital for railway construction in India. The aim of the Indian authorities is now to retain the ownership of railways in the hands of the state, to make over the construction and working of new railways, or the working or further construction of partly developed railways, to construction or working companies; to compass these arrangements with a guarantee of the lowest possible terms, whether in regard to its amount, or the length of period for which it is granted; and to provide for the reversion of the railway to the state, either by annuities, or by direct purchase after a given term of years.

Railways.

A proposed alteration of the Criminal Procedure Code, with the view of conferring criminal jurisdiction over European British subjects upon certain classes of native judicial officers in the interior, caused during 1883 the greatest excitement throughout India. By the Indian Criminal Procedure Code, as amended in 1872, extended jurisdiction over European British subjects was given to judicial officers in the interior, whose powers in such cases had hitherto been practically limited to the trial of certain classes of offences and forcible entries punishable by fine, all more serious offences being disposed of by high courts of committal. Under the code of 1872 all cases which would be adequately punished by three months' imprisonment or one thousand rupees' fine, or both these punishments combined, were made triable by a first-class magistrate; and all cases which could be met by one year's imprisonment or fine (unlimited), or a combination of both, were made punishable by sessions judges, additional sessions judges, and certain assistant sessions judges. But it was provided that the magistrate or judge must always be a justice of the peace, and himself a European British subject. In 1872 it had been proposed to modify the procedure then under revision so far as to secure to native covenanted civil servants, being justices of the peace, jurisdiction over European British subjects. The official members of the Viceroy's legislative council were divided on the point, and the motion was eventually lost by seven votes to five. Ten years later, on the 6th March 1882, a Code of Criminal Procedure was passed. On the 20th March the Lieutenant-Governor of Bengal, Sir Ashley Eden, submitted to the Government a note received by him before the passing of the code from Mr B. L. Gupta, of the Bengal civil service, a native gentleman acting as presidency magistrate in Calcutta, inviting attention to the anomalous position in which the native members of the covenanted service found themselves under the code of 1872. That law limited the jurisdiction over European British subjects in the interior to judicial officers who were themselves European British subjects, although in the Presidency towns native civilians, and indeed native police magistrates of the uncovenanted service, also had such jurisdiction over European British subjects. The lieutenant-governor expressed the opinion that a discussion on the subject could not with prudence be raised at the final reading of the Criminal Procedure Bill, and it was for this reason that he had not brought forward Mr Gupta's letter at an earlier date. But he suggested that the matter should receive full and careful consideration whenever on any future occasion a fitting opportunity occurred. Sir Ashley Eden was favourable to granting to covenanted native civilians, who had attained the jurisdiction of district magistrates or sessions judges, full powers over all classes, whether Europeans or natives, within his jurisdiction. In April 1882 the question was referred by the Government of India to the several local governments and administrations, and in September 1882 the Government addressed the Secretary of State on the subject, proposing to confine the office of justice of the peace, and with it the powers of trying European British subjects, to those persons, whether European or native, who had received a training that might be presumed to guarantee the possession of the necessary qualities. They advised that all district magistrates and sessions judges should be vested with the powers in question in virtue of their office, and by a definite provision in the law. They proposed, further, to empower the local governments outside the Presidency towns of Calcutta, Madras, and Bombay to confer these powers on members (*a*) of the covenanted civil service, (*b*) of the native civil service constituted under certain statutory rules, (*c*) certain of the classes of natives already exercising first-class magisterial powers and judged fit to be entrusted with these further powers. The majority of the Viceroy's council concurred in these recommendations, and a Bill was accordingly introduced on 9th February 1883. Immediately there arose the clamour of opposition. On the 20th of February a public meeting of the European inhabitants of Calcutta was held in the Town Hall, at which a resolution was passed denouncing the principle of the Bill, and pledging the community to oppose its progress. From that time the opposition rapidly gathered strength, and later in the year became violent beyond all precedent. The British community, with rare exceptions, united in opposing the Bill. Meetings were held throughout the country, but mostly in Bengal and Upper India. Remonstrances poured in; both the European and native sections of the community became greatly embittered. The Secretary of State for India, addressing the Government of India in November, expressed his wish that the Bill, as drafted, should be proceeded with. The measure, however, was not again brought before the legislative council in 1883, and throughout December of that year the British community was at fever heat. The Government of India hesitated to press the business to a conclusion; the opposition awaited watchfully the action of the Government.

Criminal procedure.

The Ilbert Bill.

Matters seemed at a deadlock when, on the 4th of January 1884, Mr Ilbert, who as legislative member of council was in charge of the Bill, moved that it be referred to a select committee. But before that date informal negotiations had been opened with a member of the Government through the medium of an unofficial member of the legislative council, and eventually the Bill was referred to a select committee to give effect to the following arrangement:—The Government undertook to agree in select committee to the right being given to European British subjects, when brought for trial before a district magistrate or sessions judge, to claim trial by jury, such as is provided by section 451 of the Criminal Procedure Code, subject to the following conditions: (1) No distinction to be made between European or native district magistrates or sessions judges; (2) the powers of district magistrates under section 446 of the code to be extended to imprisonment for six months or fine of 2000 rupees. The settlement thus arrived at became law without further opposition in January 1884, and remains the law on this subject to the present time. It was mainly objected to the Act as passed that the extension of the jury system in India is a retrograde measure. The compromise arrived at is believed, however, to have been unattended practically by any of the other disadvantages which were at the time urged against it; and it closed, in terms which were acceptable both to the majority of the Viceroy's council and to the public, a controversy which had become intolerable, and from which neither party could find a means of retiring.

From the seed sown in the stormy year 1883 there sprang up a plant possibly of indigenous growth, but carefully matured by friendly British hands, known as the Indian National Congress. The Congress was in some measure a response to an association calling itself the British Defence Association, and purporting to declare with similarly authoritative voice the wishes of European British subjects whom it claimed to represent. It held its first annual meeting in the winter of 1883; and it continues to meet at the close of each year, and to pass, and to publish, resolutions having for their object changes of a more or less sweeping character. Its resolutions are aimed mainly at what is alleged to be the exclusive conduct of affairs by foreigners, at legal and administrative privileges said to be confined to the ruling race, or at restrictions imposed on the free exercise of the rights of debate and public discussion by elected Indian legislative bodies. The so-called Indian Congress, though sedulously and skilfully "boomed" in its earlier years, has never succeeded in getting itself taken seriously, because the strings are admittedly pulled, and very skilfully pulled, by British hands. But the reason has also been that the Congress is representative only in so far as it represents a small section of the educated classes, who are themselves an infinitesimal section of the people; because this section, again, belongs largely to Bengal, which politically carries little weight in India; because the great body of Mahommedans is opposed to it; and because the resolutions it puts forward in no way interpret to the Government those vital emotions and impulses which ordinarily lie dormant in the breasts of the people, but which are rarely with impunity to be neglected. The Congress, in short, is not national, for there is no one nation covering the Indian peninsula. Nor, either in the persons attending it, or in the mode of their election, or in the views they put forward, are the delegates representative of so wide a range of classes as to justify them in any degree whatever in claiming to be the nominees of the public.

The Indian National Congress.

Among other prominent measures of the early years of the eighth decade was the repeal of the Vernacular Press Acts passed by Lord Lytton. In the opinion of Lord Ripon's Government, the Press Acts passed by Lord Lytton (9 and 16 of 1878) constituted a direct departure from the policy with respect to the press in India which had been followed by the Government of India for upwards of forty years. It was the aim of these Acts to restrain the press, which was stated to have been at that time markedly seditious in its tone. They provided that a paper, after having been warned, would be liable to suspension, and they applied not only to publications of a nature to excite disaffection and endanger the public peace, but also to those affecting private persons and public servants. Other objections apart, it was held by Lord Ripon's Government that an invidious exception was thus permitted in favour of the English press; and it was contended that if the Penal Code did not meet such cases, the existing defect in the code might be remedied. Acts 9 and 16 of 1878 were accordingly repealed. Later, in 1898, in consequence of plague riots in Poona, the murder of two British officers in retaliation for alleged insults to native usage and custom in the searching of women's apartments, and of much seditious writing connected therewith in the Bombay press, the Penal and Criminal Procedure Codes were respectively amended by Acts 4 and 5 of 1898, which rendered the law in regard to seditious writing very considerably more stringent.

Press Acts.

From Lord Ripon's tenure of office date also the revival and reorganization, in accordance with the recommendations of the famine commission of 1878, of an agricultural department, whether in the Government of India or in provincial governments. Such a department had already been brought into existence in 1871, but only to be abolished in 1877. Agricultural inquiry, agricultural improvement, and famine relief were the subjects to which the attention of the department, as revived, was especially directed. In all these branches (more especially in the third) the measure has given useful results, and the department has now taken its definite place in the circle of Indian administration. But exhaustive inquiry and minute survey of local requirements throughout the vast area of India must precede any far-searching reforms in its agriculture. Further, there must be both the will and the power among landlords to expend capital in experiments and in improved methods of cultivation. It is only by slow degrees and with the lapse of time that material results can be hoped for in this direction. The relations of landlord and tenant, especially in Bengal, in Oudh, and in the Central Provinces, formed also at this time the subject of legislation. It was not till the tenure of office by Lord Dufferin that the Bengal and Oudh Rent Bills actually became law; but they had been framed and prepared and made almost ready for legislative sanction before his predecessor resigned office. They aimed at securing to the cultivating tenant a more stable interest in his holding, and they modified previous legislation principally in this direction. It was desired to secure tenants of all kinds of classes, in degrees varying with their occupancy rights, against arbitrary eviction or inequitable enhancement of the rents of their holdings. Compensation for improvements and for disturbance was in many cases arranged for. In Bengal, and in a lesser measure in Oudh, the objects aimed at by the legislature met with strenuous and organized opposition. In both provinces the landlord had hitherto enjoyed in a degree unusual in India the power of rack-renting and evicting his tenants. In neither province had he shown solicitude for the tenant by whose labour he so largely profited. Unless coerced by legal provisions, the landlord

The Land question.

in Bengal or the Oudh Talukdhar was little likely to improve the tenants' position to the prejudice, as he conceived, of his own. In India, as elsewhere, there have always been two opposed points of view, viz., the point of view of those who regard the land as the property of the landlord, and the tenant as an intruder and an encumbrance; and the point of view of those who reverse the position, and see in the tenant the party with vested interests in the soil, and in the landlord a useless interloper. The Bengal and Oudh Rent Acts dealt with a vast variety of local tenures and sub-tenures and complicated questions of tenant right in a spirit of equity and moderation. The result has been everywhere beneficial. Speaking in general terms, it may be said that legislation was more favourable to the tenant than to the landlord. The dust of controversy has since settled down, and the new legislation has become the rule of practice. With protection from arbitrary enhancement of rent and with security of improvements, we may more and more expect to see property accumulated, credit grow up, and improvements effected in the system of cultivation. There could have been no greater misfortune to the country than that the numbers of the occupancy class should decrease, and that such tenants should be merged in the crowd of rack-rented tenants at will who, owning no permanent connexion with the land, have no incentive to thrift or to improvement. It was desirable for all parties that measures should be framed to secure the consolidation of occupying rights, the enlargement of the numbers of those who held under secure tenures, and the widening of the limits of that security, together with the protection of the tenant at will in his just rights and the strengthening of his position by any wise or equitable measure. It is indeed probable that too little, not too much, has been accomplished. The landlord, on whom, in compliance with English analogies framed in the time of ignorance as to local tenures and customs, there were conferred proprietary rights of a nature and extent unknown either to Hindu or Mahommedan law or precedent, is still by far the most powerful and the least valuable asset in the Indian agricultural economy. There are in this, as in all other matters, notable exceptions. But, generally speaking, in those provinces where the soil is best cultivated, where its proceeds are most equally distributed, where the villages are most flourishing, where cattle, fodder, and manure most abound, where contentment and a moderate and reasonable prosperity most palpably meet the eye on every side, we may be sure that the cultivator is himself the proprietor of the land he tills, or is protected by law from arbitrary exaction and from unconditional ouster.

Legislative results.

The year 1885 furnishes the high-water mark of peaceful and uninterrupted progress. From that date clouds again began to accumulate around and about the Indian horizon. Before that year was over Great Britain had been nearly plunged into war by a collision between Russian and Afghan troops at Panjdeh, in Central Asia. Over £2,000,000 had been expended in hurried war preparations; commercial and famine railway extension had been arrested, and a large scheme of unremunerative military railways had in part overlaid and superseded it. Then came, almost on the heels of the Panjdeh incident, the outbreak of the Burma war, which in one or other form dragged on for the space of nearly two years. Meanwhile, in view of the approach of Russia in Central Asia, the Government of India had decided to increase the effective strength both of its British and native army, the former by 10,000, the latter by 20,000 men, at an estimated annual increase of little less than 1½ million sterling. Military defence works and measures for more speedy mobilization added largely to prospective military expenditure. Exchange, which had remained for the space of three or four years fairly stationary, again resumed its downward course. A succession of costly frontier wars was entered on; and, as in 1878, before long the attention of the Government was once more diverted from all home questions. Finally, though at a later date, came a recurrence of famine and the appearance in India of the bubonic plague. Such, during the period from 1885 to 1900, was the accumulation of disastrous circumstances, some of which it was not in the power of the Government of India by the exercise of any prudence or wisdom to avert. Following rapidly one on the other, they again obstructed indefinitely that uncertain and hesitating path of progress which is so soon lost or choked by the sudden and tropical growth of tangled troubles in India.

Before, however, all this had finally occurred, one or two measures of importance remain to be noticed, which originated with Lord Dufferin's Government, though they were in their final stage put into execution by his successor. They are marked by the desire to conciliate native opinion, and to provide a field for the due expansion of native ambitions, which had uniformly characterized the administration both of Lord Dufferin and of his predecessor. In October 1886 a strong mixed commission was appointed by the Government of Lord Dufferin to inquire into the system under which natives of India were at that time admitted by statute to the covenanted civil service, or to offices formerly reserved exclusively for members of that service; and also their employment in all branches of the public service connected with the civil administration of the country. The object of the appointment of the commission was, broadly speaking, to devise a scheme which might reasonably be hoped to possess the necessary elements of finality, and to do full justice to the claims of natives of India to higher and more extensive employment in the public service. The commission was presided over by the late Sir Charles Aitchison, at that time Lieutenant-Governor of the Punjab. It included a former chief justice of the High Court of Judicature in Madras, several civilian and native officials of high standing, and well-known English and native non-officials. The commission presented a report at the close of 1887, dealing with all branches of the civil administration. The more important recommendations were those which concerned the admission of natives of India, Eurasians, or European British subjects domiciled in India into the higher grades of civil employment. This was a matter which had at various times come before the Government of India, and had been dealt with by successive statutes in 1861 and 1870. The object of section 6 of the latter statute had been to provide "additional facilities . . . for the employment of natives of India of proved merit and ability in the civil service of her Majesty in India." It empowered the Government of India, with the sanction of the Secretary of State, to make rules for the appointment of natives of India to posts in the civil service, although such natives had not passed the competitive test in England. By native was meant any person born and domiciled in British India, of persons habitually resident in India, and not established there for temporary purposes only. Rules were framed under this statute in 1873 and 1875, and finally in 1878, these latter being the rules in force when the commission met to reconsider the question. Under the rules of 1878 a proportion not exceeding one-fifth of the total numbers of civilians appointed by the Secretary of State to the civil service in any one year were to be natives selected in India by the local

Civil Service reform.

governments, and each such candidate was to be, save in exceptional circumstances, regarded as on probation for two years. The commission found, and no doubt justly, that the existing "statutory system," as it was called, had failed to fulfil expectation, and that it was generally condemned and should be abolished. They went on to record their opinion that, in the present circumstances of the country, the claims of natives of India to higher employment and the admission of competent natives to a due proportion of the posts hitherto reserved for the covenanted civil service, would be best met by reducing the covenanted civil service to a *corps d'élite*, by limiting its numbers to what is necessary to fill the chief administrative posts of the Government and such a number of the smaller appointments as would ensure a complete course of training for junior civilians, and by transferring a corresponding number of appointments to a local service to be recruited in each province of India. They preferred to substitute for the old term, "Covenanted Civil Service of India," the expression, "Imperial Civil Service," and to reduce the number of appointments expressly reserved to that service under the schedule attached to the statute 24–25 Vict. cap. 54. They desired that, even to appointments reserved in the schedule, special nomination might be made under due authority on account of noted merit and ability. The higher appointments thus excluded from the schedule were to be amalgamated gradually with the higher appointments in the executive and judicial departments of the then existing uncovenanted service, being the service subordinate in status to the covenanted civil service, and previously excluded from most of the higher administrative offices. In future this service would be recruited locally under rules to be made by the Government of India, and would be called the "Provincial Civil Service." Below this again would be a "Subordinate Civil Service," disposing of the lower range of executive posts. Rules were prepared for recruitment, raising of salaries, and so on, with which we need not here concern ourselves. The recommendations of the commission, with comparatively unimportant reservations, were accepted by the Government of India and the Secretary of State for India, and are at the present moment in force. They have greatly improved and strengthened the prospects of higher employment to all classes of natives of India, and have for some time to come, it may be reasonably anticipated, set at rest agitation on this point. It is not to be understood that all the higher appointments thus made available to the provincial civil service were at once made over to the members of that service. It could be by degrees only, with promotion and changes among present incumbents, and with a sufficient number of duly qualified provincial civil servants competent to fill such appointments, that the new rules could be fully applied. But in future a very considerable proportion of the higher administrative posts in India will be available to natives of the country; and they can claim them as of right, if qualified by length of service, by ability or by merit, or by the tests prescribed under rules for the time existing.

Another very important innovation, originating with the Government of Lord Dufferin, was carried into effect in 1892–93, to which statutory effect was given by the Indian Councils Act of 1892, having for its object the introduction of the elective system into the nomination of non-official members of the several legislative councils, and greater latitude of inquiry by such members into administrative matters. Hitherto the members of these councils had been nominated by the several Governments, and debate took place only when Bills came up for consideration. No administrative act of the Government could be directly brought under discussion. Certain municipal corporations and local boards are now allowed the right of recommending a member designated by themselves for a seat on the provincial council. Considerable classes of landlords are given the same privilege. In some cases the chamber of commerce and the local university recommend a member. In the Viceroy's legislative council six are in future to be official members, and five are to be appointed on the recommendation of the non-official additional (legislative) members of the councils of Madras, Bombay, Bengal, and of the North-West and Oudh respectively, and by the Calcutta chamber of commerce. The Governor-General is empowered at his discretion to nominate to such of the remaining seats as shall not be filled by officials (the maximum number of seats being sixteen), in such manner as appears to him most suitable with reference to the legislative business to be brought before the council and the due representation of the different classes of the community. It is obvious that the measure is tentative, and that the admission of the elective principle is safeguarded by the most stringent restrictions. Thus the additional members to be designated by elective bodies in any legislative council form a minority of the total maximum number of its members; the rest are directly nominated by the head of the Government. The recommendation of the local elective bodies may be disregarded; everywhere the nominees of the Government form the majority. It must be remembered further that the legislative council meet for purposes of legislation only, and have no power or authority to discuss, except incidentally in the course of debate, matters of policy or administration. But in remodelling the legislative council a further step was taken towards the introduction of a system of debating, permission being given to discuss the annual budget, heretofore allowable only when legislation affecting taxation was before the council; and also, under strict rules, to use the right of interpellation or of asking questions on matters of administration or general interest.

Indian Councils Act.

A measure was introduced by Lord Dufferin's Government which concerns rather the military and political than the internal administration of India, but which cannot be wholly regarded as outside the general scope of Indian affairs. At the time of the Panjdeh difficulty in 1885, when war with Russia seemed imminent, all the leading native princes made offers of pecuniary aid. Their offers were refused, but it was intimated to them at a somewhat later date that if they would place a small military force in each state at the disposal of the British Government, to be commanded by state officers, but drilled, disciplined, and armed under the supervision of British officers and on British lines, the Government would undertake to find the necessary supervising officer, arms, and organization. The offer was universally accepted, and the Imperial State troops, as they are called, amount at present to nearly 18,000, mainly cavalry and infantry, whose efficiency is very highly thought of. They rendered good service in Chitral and Gilgit, in the wars on the north-west frontier, and in China. The total native state troops are said to number, inclusive of this body, about 110,000, largely an ill-armed and ill-disciplined rabble. The Imperial Service troops, therefore, amount to about 16 per cent. of the total number.

Imperial Service troops.

By resolution of the House of Commons a royal commission was asked for to inquire into the opium question; whether, among other matters, the growth of the poppy and the sale of opium should be prohibited in India except for medical purposes; the effect of such prohibition on the

finances; the amount and effect of consumption, in regard to the moral and physical condition of the people; the attitude of the people of India towards prohibition, and their willingness to bear in whole or part the cost of prohibitive measures. A royal commission was accordingly appointed and reported in 1895. It found no evidence of extensive moral or physical degradation from the use of opium. Opium-smoking, it stated, was little practised in India. It was not shown to be necessary, or demanded by the people, that the growth of the poppy and manufacture and sale of opium in British India should be prohibited, except for medical purposes. The people of India would be unwilling to bear the cost of prohibitive measures. One member of the commission dissented from the report, and from the conclusions recorded by the majority. But the result of the inquiry justified the report, and the anti-opium agitation was laid for a further term of years.

Opium question.

The second general census of India was taken in 1891. The population of India, with an area of 1,560,160 square miles, was returned as 287,317,048, being 184 to the square mile. The total urban population numbered 27,251,176, being 9·5 of the total population, and residing in 2035 towns, of which 1401 did not contain as many as 10,000 inhabitants. Of these towns Bombay (821,764) headed the list, Calcutta (741,144) came next; no other town except Madras (452,518) had as many as 450,000 inhabitants. The proportion of sexes was 958 females to 1000 males. Mahommedans formed 20 per cent. of the population, Hindus more than 72 per cent. The third census, taken in 1901, showed a total population of 294,266,701. Calcutta, with its suburbs, had grown to 1,121,664, but Bombay had declined to 770,843, owing to the devastation of the plague. Madras, however, had advanced to 509,397.

Census.

In 1897 Burma was raised to the status of a lieutenant-governorship, and a legislative council was conferred on that province and on the Punjab, such as existed already for the other lieutenant-governorships in Bengal and the North-West Provinces.

Surveys and land revenue settlements are always in progress in one or other of those districts of an Indian province where the land revenue is fixed for a given period, and which are known, therefore, as temporarily settled districts. But a cadastral survey is also for the first time in full progress in the permanently settled districts of Behar, in the lieutenant-governorship of Bengal, having for its object the record of tenant holdings and the settlement of rents. This, when completed, should be of great value. Forestry has been the object of much attention in later years, and is retained by the Central Government mainly under its direct control. We read in the volume exhibiting the moral and material progress and condition of India (1898–99) that "Within the last twenty years forest laws have been enacted for, and forest administration has been placed upon a permanent basis in, every province of India. The superior officers of the forest service have been, for the most part, selected by competition, and have been trained in forestry, either in Germany, or in France, or at Cooper's Hill College. During the year 1893–94 it was decided that 20 per cent. of the 210 superior posts in the forest department should eventually be filled by selected officers, chiefly natives of India, from the subordinate or provincial branch of the department. Some of the subordinate officials are trained at a forest school near Dehra, in the sub-Himalayan country of the North-Western Provinces, and this system of professional training at local centres will be gradually extended. The first object of the forest administration is to select, acquire, and mark off as reserves an area of state forest in every province sufficient to supply the wants of the neighbourhood and the province in respect of timber, firewood, bamboos, canes, and other forest produce, and sufficient also for supplying the foreign demand for such articles as teak timber, sandalwood, and rubber. The reserves are, or will be, surveyed, conserved, and worked on sanctioned plans, designed so as to obtain the largest possible permanent yield in the most economical way. Private rights in the reserves are bought out or compromised. Among the most important measures of conservancy are the exclusion of the yearly fires which used to devastate forests, the maintenance of adequate seed-bearing trees, and the regular reproduction of timber of the more valuable kinds. At the present time the reserves cover an area of more than 80,000 square miles; and they may hereafter be further extended in Madras and Burma, where the work of reservation is as yet incomplete. Outside the reserves are over 30,000 square miles of state forests, some part of which will be eventually brought within the reserve area, and all of which are managed and worked for the benefit of the people, of their cattle, and of the public revenue. The limited areas of private forest are, except where they have been leased to the Government, being gradually exhausted; and as yet few private, and no communal, forests have been successfully brought under conservancy. In every province a very few of the most valuable timber trees are declared to be reserved trees, and can only be felled under special license. Outside the reserves, the country folk are generally allowed to obtain from the state forests timber, bamboos, firewood, and grass for their own use, free of charge; inside the reserves, only persons specially licensed are allowed to extract timber or other produce, on payment of fees. Forest revenue is raised by royalties on, or by the sale of, timber or other produce, and by the issue at specified fees of permits to graze cattle, or to extract for sale timber, firewood, charcoal, bamboos, canes, and other minor forest produce." The net revenue from forests amounted in 1900–1901 to £536,400 sterling (revenue, Rs.19,195,000; expenditure, Rs.11,120,000; excess of receipts, Rs.8,075,000—equivalent in sterling at Rs.15 = £1, £538,300; expenditure in England, £1900; net revenue, £536,400).

Forests.

Of late years much attention has also been given to the improvement of the police force throughout India. Natives of respectable position are usually unwilling to enter the police force, from fear of the risk of finding themselves entangled in some ruinous intrigue, or, at the least, of being exposed to false charges and malicious accusations; from dislike, too, of rubbing shoulders with bad characters, and moving habitually in an atmosphere of dishonesty and disreputableness. Till of late years the pay and advancement of all grades in the police force have been too inconsiderable to preserve the members of the force from temptation. Hence there was no inducement from either side to take police service, and the force has suffered in consequence both in efficiency and in *morale*. In the absence of an intelligent press and of a powerful bar, and in presence of a timid and ignorant public, the police are believed very generally to abuse their opportunities; and although not inefficient in the maintenance of order, they are little to be trusted in the detection of crime. On the other hand, it must be allowed that there has been in this regard a material improvement, dating from inquiries set on foot under Lord Dufferin's *régime*; and that in the police, no less than in other departments, the standard of quality improves with time.

Police.

It has been already said that the scheme for railway extension, which had been considered and matured by Lord Ripon's Government, came finally into operation

under the administration of Lord Dufferin, his successor; and a brief sketch may now be given of the measures then proposed and their practical outcome at the present day. Lord Ripon's Government had proposed in 1883 that there should be completed by the state or under its control, in the space of about five years, a programme having for its object the construction of 3837 miles of railway, including lines in progress, at an estimated cost of $27\frac{1}{2}$ millions. Nearly the whole of the projected mileage was for protection against famine, but about 1500 miles only were regarded as likely to be financially unproductive. For the construction of these lines three agencies were proposed: that of Government itself for about 1915 miles, that of construction and working companies for 437 miles, and that of private companies under limited guarantee for 1484 miles. It was also proposed that certain other railways should be constructed by private enterprise, unaided except by the free grant of land, such lines being of a commercial character, and not mainly needed, as in the case of the mileage above referred to, for protective purposes. It is not necessary to follow here the subsequent changes introduced into the programme by the course of events and by instructions emanating from the India Office. It is sufficient to add that the proposals of the Government of India were in due course submitted to a select committee of the House of Commons, who reported in July 1884. The conclusions laid down by that committee, which principally concern us here, were as follows:—That the evidence in favour of a more rapid extension of railways was conclusive; that all the leading trunk lines, with their principal feeders, should be on the broad gauge; that the amount proposed for expenditure by the Government of India was moderate; that the $2\frac{1}{2}$ millions' limit of annual borrowing fixed in 1879 might safely be enlarged; that a fixed scale of expenditure should be maintained over a considerable term of years; that the bulk of lines should be made self-supporting; that railway extension should not involve fresh taxation. Before, however, effect could be given to the proposals put forward in 1883, as subsequently modified by the Secretary of State, there occurred the incident of Panjdeh. The Government of India in the spring of 1885 found itself on the verge of war with Russia, and the defects in its frontier communications and want of facilities for the transport of troops and stores were urgently pressed upon it by its military advisers. As a limited sum only could be spared from loan funds annually, and as it was to such funds mainly, apart from the famine insurance annual grant, that expenditure professedly unremunerative could be charged, it followed that the programme of construction adopted in 1884 had even at this early date to be reconsidered. Pressure on the finances both in 1885 and in certain subsequent years, whether from war preparations or from financial difficulties more or less connected with the burden of exchange, has from time to time interrupted the execution both of the original and succeeding programmes. But railway extension has been pursued as steadily as circumstances would allow.

Railway extension.

The following statement shows the length of railway actually constructed and open throughout British India and in native states at the date of 31st March 1901:—

Standard Gauge, 5 feet 6 inches.

	Mileage open.	
State Lines worked by Companies—		
East Indian	1836·15	
Bengal Central	125·01	
Bengal-Nagpur	1190·16	
Indian Midland	796·25	
Miscellaneous	365·15	
		4312·72
State Lines worked by the State—		
North-Western	1913·90	
Frontier Section of (Military)	1039·90	
Haidarabad-Shalipulli	58·91	
Oudh and Rohilkhand	950·76	
Eastern Bengal	268·04	
Calcutta Port Commission	8·53	
East Coast	803·25	
		5043·29
Lines constructed by Guaranteed Companies—		
Great Indian Peninsular	1307·00	
Bombay, Baroda, and Central India	460·90	
Madras	844·23	
		2612·13
Lines constructed by Assisted Companies—		
Luckeeserai-Gya	78·83	
Delhi-Umballa-Kalka	162·24	
Tarkessar	22·23	
Southern Punjab	423·72	
Hardwar-Derha	32·05	
Tapti Valley	155·77	
		874·84
Lines owned by Native States and worked by Companies		703·55
Lines owned by Native States and worked by State Railway Agency		122·97
		13,669·50

Metre Gauge, 3 feet $3\frac{3}{8}$ inches.

State Lines worked by Companies—		
Burma	993·29	
Bengal North-Western (including the Tirhoot State Line)	1157·97	
Lucknow-Bareilly	231·17	
Rajputana-Malwa	1674·57	
Palanpur-Deesa	17·28	
Southern Mahratta	1042·04	
Gantakul-Mysore	119·50	
Mysore Section, South Mahratta	296·00	
South Indian	1030·53	
Mayavaram-Mutapet	54·08	
Assam-Bengal	435·45	
		7051·88
State Lines worked by the State—		
Eastern Bengal	565·03	
Cawnpore-Burhwal	79·60	
		644·63
Lines worked by Assisted Companies		347·56
Lines owned by Native States and worked by Companies		381·58
Lines owned and worked by Native States		997·98
		9423·63
Special Gauge		597·50

We have thus a total open for traffic on the 31st of March 1901—

Standard Gauge	13,669·50
Metre Gauge	9,423·63
Special Gauge	597·40
Total	23,690·53

On the same date 3018·03 miles were under construction or sanctioned for construction.

Of the above list, the principal lines commenced and completed since 1884 have been the Bengal-Nagpur (1190 miles open), the Indian Midland (796 miles open), the great majority of the frontier (military) sections of the North-Western (1039 miles), the East Coast Railway (803 miles), the Bezwada-Madras (254 miles), the Delhi-Umballa-Kalka (162 miles), the Southern Punjab (423 miles), in part the Bengal North-Western (about 440 miles), the Lucknow-Bareilly (231), much of the Southern Mahratta (say 440), the Assam-Bengal (435), the Burma railway (in part about 650 miles), in all, 6863 miles. Taking the mileage in 1878 at 8250 miles, we have therefore an increase of 15,440 in twenty-two years, and the average of, say, 700 open miles per annum.

The later famine commission in its report of 1898 recorded its opinion that most of the necessary protective railways had been completed, and that in existing circumstances greater protection from famine would be afforded by the extension of irrigation works than by construction of further protective railways.

It will be seen that 13,669 of a total of 23,690 miles are on the standard gauge. The select committee of the Commons in 1884 had laid it down that all the leading trunk lines, with the principal feeders, should be on this gauge; the metre gauge

being, as a rule, confined to tracts of country where that system was already in successful operation, and to local lines where the traffic is so light that cheapness of construction more than counterbalances the undoubted disadvantages of break of gauge. The state railways completed or under construction in 1880 have been mostly carried out by allotments from the annual rupee loan of $3\frac{1}{2}$ millions, by assistance from the famine grant, and from funds supplied by construction and working companies having some form of limited guarantee. Thus the Indian Midland and Bengal-Nagpur Companies, both of which have constructed and worked state lines, receive interest on the share capital raised by them in sterling at the rate of 4 per cent. per annum and one-fourth of the surplus profits, that is, of the excess of the net earnings over annual interest on the total capital provided. The Burma railway, also a state railway worked and partly constructed by a company, is guaranteed $2\frac{1}{2}$ per cent. per annum on share capital, retaining in addition one-fifth of surplus profits. The Secretary of State guaranteed, however, to the company up to the 30th of June 1901 not less than $\frac{1}{4}$ per cent. per annum on paid-up share capital as its one-fifth share, thus making the total guarantee up to that date $2\frac{3}{4}$. In all cases there is reserved to the Secretary of State the right to terminate the contract by a given date and on specified terms. It is not necessary further to describe the terms of guarantee given in the case of other less important railways, but it may in general terms be added that the financial conditions imposed on working and construction companies have become progressively less favourable to the companies. In the case of the Bengal and North-Western, no guarantee of interest having been given by the Secretary of State, all net earnings belong to the company. The Rohilkhand and Kumaon Railway also receives no formal guarantee, except during construction; but on the opening of the line an annual subsidy was granted for a period of twelve years from registration of the company, and a fixed sum for carriage of mails throughout the term of contract.

All capital raised from time to time by guaranteed companies is paid into the hands of the Secretary of State, who pays the guaranteed rate of interest on such deposits, which, however, is a first charge on the net earnings of the open line. The Secretary of State annually reallots to each company from the funds deposited a sum based on its requirements for construction of main and feeder lines, as determined, not by itself, but by a commission of officials sitting in India *en permanence*, by which quinquennial forecasts are made, for each guaranteed railway, of the works to be annually carried out. Thus the guaranteed or assisted companies are financially in the position of departments of the state administration rather than of quasi-independent bodies. In ordinary times no great inconvenience may result from this procedure. But in times of financial stress, such as not infrequently occur in India, the deposits of the companies may be partly needed for the cash requirements of the Secretary of State; and construction is delayed until it is found convenient to replace at the companies' disposal sums which may be urgently required for their needs. Their progress is therefore regulated, not so much by their own financial position, as by the requirements of the Government of India. These vary with the seasons, with war or peace, with a hundred disturbing forces, so that the guaranteed railways are sometimes allowed the use of their own funds, and sometimes are denied it, and their development is liable to be constantly arrested. Only in the case of the East Indian Railway have independent powers of borrowing been given by statute. A Government director, nominated by the India Office, attends each London board's sitting of a guaranteed company, and the Secretary of State is kept informed of the progress of its affairs.

The financial results to the state of working Indian railways, according to the estimates for the financial year 1899–1900, were as follows in conventional sterling:—

Losses.	£	Gains.	£
Guaranteed railways	733,900	State railways, commercial	52,600
State railways—			
Military state lines	664,600	State lines, worked by companies	2,288,600
Leased to companies	629,500		
State railways commercial unopen	82,800		
	2,110,800		2,341,200
Add charges debited to land, supervision, and miscellaneous	243,100	Add total Loss	12,700
	2,353,900		2,353,900

The total loss to the state, therefore, was apparently £12,700 on the year's working. But of the charges a considerable sum was due to annuities paid in England, comprising a large contribution for sinking funds for redemption of capital. Of the loss of £2,110,800 in 1898–99, the sum of £664,600, it will be observed, is due to military railways. The loss on the three great "guaranteed" railways is £733,900. The latter source of loss will be lessened as the railways in due course are successively bought up by the state.

Including unfinished lines, the total capital expenditure in all India, from the commencement of railway construction up to 1st December 1899, amounted to 302 crore of rupees (the crore being a million sterling at 10 rupees = £1):—

Standard Gauge.	Metre Gauge.	Special Gauge	Unclassified Expenditure	Total.
220·43	78·94	2·09	0·82	302·28

"The policy," says the royal commission on the administration of the expenditure of India (1900), "under which capital and expenditure amounting to Rx.288,000,000 have been incurred" (this was up to 1898–99 only), "must give opportunity for wide differences of opinion. Some may think that progress has been too fast, some that it has been too slow. There may be legitimate questions as to the manner in which money for these great works has been raised, or as to the amount of outlay on working expenses. There is no necessity for us to enter into these questions. We deal with the facts as they are, and on these facts we think that the Indian taxpayer of the present obtains the benefit of a vast railway system at a comparatively light cost; that the fall in exchange has subjected the financial result of the Government railway policy to very severe trial; that if the loss on purely military lines were transferred to military expenditure, and if the charge of famine protective lines and of lines under construction were eliminated, there would be no charge on the taxpayer—in other words, that the true commercial lines pay their way; and that there is a fair prospect with improved exchange that the charge on the taxpayer will, even on the account as at present presented, entirely disappear. If a fair and constant surplus should hereafter be realized, it will be reasonable subject for consideration whether larger sums might not with advantage be devoted to improvement of the lines, but we quite understand that the Indian Government make it an object in the first instance, and within reasonable limitations, to relieve the taxpayer of any charge in respect of railway administration."

Results of the railway policy on finance.

It would be sanguine to look for a fair or constant surplus, since much remains yet to be done in Indian railway construction of a more or less unproductive nature. The profit on commercial lines will very probably be neutralized for years to come by calls for further protective and military railways which may be to-day unforeseen, but which, if experience should guide us, will to-morrow be declared to be indispensable. That commercial lines, if wisely selected, will yield a fair profit admits of little question. But, in respect of the taxpayer, state railway expenditure must be taken as a whole. There is little practical use in contending that if certain conditions ceased to exist results would prove more favourable, unless there are good grounds for anticipating a change in such conditions. As a matter of fact, the charge for railways has for long years weighed heavily on Indian finance. The gain to India may, notwithstanding, have been greater than the burden of the charge. This is matter of opinion. But to meet the difficulty by a series of assumptions such as those above quoted, viz., that if exchange had been more favourable, or if frontier lines had been charged to military expenditure, or if protective lines had been separately shown, the net profit on commercial lines would have been greater, will not in any way assist the taxpayer. If another method of bookkeeping had been adopted the burden would have been shifted, but not lightened. The deficit would still have to be met, and the charge on the taxpayer would remain the same. Reckoning from 1858–59

to the end of 1899, the total loss to the state on the railway account has been £57,811,487, which, in general terms, may be looked on as the price at which its railway experience and the indirect advantages resulting from the construction of railways have been acquired by the Government of India.

In 1896 the Government of India drew up and published the terms on which it was prepared to consider offers for the construction by the agency of private companies of branch lines, ordinarily not exceeding 100 miles in length, forming feeders either to state lines worked by the state or to railways worked by companies. It is too early yet to be assured that the terms so offered will lead to any considerable extension of feeder lines.

Irrigation has been dealt with in another article. The Indian service, to its credit, has furnished a school of irrigation engineers which has of late years applied to Egypt its resources and experience, and which apparently is destined to repeat in that country and in the Sudan its former triumphs in the Gangetic valley, in Madras and Mysore, and in the arid Punjab plains.

The practical working of the famine grant from 1880–81 to 1899–1900, under the various heads of famine relief, railway and canal construction, and reduction of debt, has been as follows. Nearly £29,000,000 has been distributed from the current revenues which furnish the grant, under the following heads:—

Famine Relief.	Construction of Protective Irrigation Works.	Construction of Protective Railways	Reduction and Avoidance of Debt.	Total.
7,776,097	1,941,688	12,853,885	6,353,799	28,925,469

As the protective railway mileage contemplated by the Government has been practically completed, the famine grant would seem to have done its work. The special taxation devoted to it might be thought therefore to be no longer justifiable. But in the financial statement for 1900–1901 the maintenance of the grant was thus explained:—"The programme of purely protective railway works has been practically exhausted, and that of irrigation works has been much reduced of late years, and, though the latter may be capable of some expansion, the expenditure on these works will not be large, while the amount required to cover the loss on the Indian Midland and Bengal–Nagpur railways, which it was specially decided to charge to the grant some years ago, will not usually exceed Rs.30,00,000. There will therefore, now that the grant is relieved from charges for such railways as the East Coast and South Indian, be a large balance in normal years when there is no direct expenditure on famine, a balance likely to increase as the loss on the Indian Midland and the Bengal–Nagpur lines diminishes. It has hitherto been the practice to show this unappropriated balance under the heading of reduction of debt, a heading which has puzzled people who ask how there can be a reduction of debt in a year when fresh loans are raised or in which no debt is discharged? We hope to clear up the difficulty by altering this heading to that of reduction or avoidance of debt. It may lead people to grasp more readily what is actually happening in a normal year. In such a year the Indian Government raises more revenue than it actually requires to meet its ordinary charges against revenue by the amount of the unappropriated balance of the famine grant. This amount is devoted to expenditure on public works which would otherwise have to be provided by loan. For instance, in a normal year, in which ordinary revenue and expenditure balanced, the Government of India, instead of raising a loan of three crores for public works, would be able to reduce the three crores by the unappropriated balance, say a crore, of the famine grant. Less debt would be incurred in normal years, and the credit of the Government would be higher when it was compelled to borrow."

Sanitation.

Sanitation makes comparatively little progress in India. Difficulties caused by climate, by long periods of drought succeeded by torrential rains, by the great heat, the vast, flat alluvial plains, the overcrowded population and their habits—above all, by the need of very large sums and the difficulty of finding even a fraction of them—interpose an insuperable barrier to rapid progress. Still something is annually done. The Presidency towns have a good supply of water, and are tolerably drained. The large cities in the interior, notably in the North-West Provinces and Oudh, have supplied themselves with waterworks and pumping machinery, which ensure an ample supply. Situated, as the majority of these cities are, on the banks of great rivers, the business of providing themselves with a good supply of suitable water has proved comparatively simple. But in all of them drainage is still in its infancy, and the system in force can be described as little more than makeshift or elementary. In the rural villages some slight attempts have been made to grapple with the difficulties at least of a good water supply. Here again similar obstacles present themselves. Nothing could be more unjust than to charge the provincial governments with indifference to the subject. Sanitary officers and officials in every province alike labour to introduce a better order. But for the reasons given, the circumstances and conditions are not such as to justify the hope that they will achieve any very rapid or signal success. Meanwhile, a fresh factor has been introduced into the problem. The appearance of plague in India has placed sanitary reform, once and for all, in the foreground of the country's needs.

In every large or important town are one or more hospitals supported partly by the provincial governments, partly from private subscriptions, and served by the Government medical staff. In the rural population dispensaries are established, and are maintained partly by private subscriptions, partly by grants in aid. In 1898–99 their number and distribution were as follows:—

Province.	Number of Dispensaries.	Number of Dispensaries, Square Miles.		Number of Patients per Dispensary.
		Square Miles in Dispensary.	Population in Dispensary.	
Bengal	487	311	145,103	5,913
Bombay	337	371	56,086	5,074
Madras	496	280	71,835	8,161
Central Provinces	121	591	78,524	12,499
Punjab	265	417	78,720	12,232
North-West Provinces	331	324	141,707	10,983
Burma	99	1731	76,820	7,620

Mention may here be made of the medical aid and relief for women, the building of women's hospitals, and the arrangements for the education and training of lady doctors and female nurses, which have been inaugurated since 1885 under the auspices of the Countess of Dufferin's fund, and embodied in the National Association for supplying female medical aid to the women of India. The fund owes its origin to the humanity, energy, and wisdom of the Marchioness (at that time the Countess) of Dufferin.

In 1900 there were twelve branches working under the central committees. There were 235 hospitals, wards, and dispensaries of various kinds for the treatment of women by women. In the above hospitals or in their

homes 1,519,990 women and children received medical relief during the year under review. Thirty-three lady doctors of the first grade, 73 assistant surgeons, and 271 hospital assistants and practitioners of the third grade were employed in zenana hospitals and institutions. Three hundred and fifty-four women were studying medicine in the various medical colleges and schools in India. This association, and the institutions supported by it, are of invaluable service to the women of India. Large sums have been subscribed, mainly in India, and are invested in its behalf, so that it is self-supporting. Not only has it proved of incalculable benefit to women, especially of the classes who are precluded from attending public hospitals and are now enabled to receive female medical advice and treatment at their own homes, but it has liberated for the use of males a large number of wards in the general hospitals which had been heretofore assigned to women.

In 1896–97 India was revisited by famine, and the bubonic plague, which has since been constantly present in more or less virulence, first showed itself. The famine of 1896–97 extended over some 310,000 square miles, with a population in round figures of 35 millions, and was most severe in the North-West Provinces, in Oudh, and in the Central Provinces. It lasted from about September 1896 till October 1897. At the worst time the total numbers on relief were 4,609,000. The death-rate per mille in the famine districts rose from 32·80, the normal death-rate, to 39·54. The total Government expenditure and loss to Government is estimated at about 17¼ millions. A commission was appointed at the close of 1897 to report on the working of the Famine Code, and on the sufficiency of measures taken to combat famine. It reported in the ensuing year. The bubonic plague was first identified in Bombay city towards the end of September 1896, and afterwards spread to the Deccan, the western districts of the Nizam's Dominions, the Punjab, the North-West Provinces, and Bengal. From September 1896 to the end of April 1900 the reported plague deaths in the whole of the Bombay country were 299,844, and 58,841 for other parts of India, while the actual plague deaths were probably considerably more. The Bombay and Karachi export trade has been seriously affected by the plague. Grievous as is the mortality from plague, a total even, say, of 475,000 for a period of nearly four years is less than the difference between the highest cholera mortality (727,493 in 1892) and the lowest (152,703 in 1898) in British India in a single year. In November 1898 a mixed commission, consisting of three medical experts from the United Kingdom and two Indian officials, was appointed to investigate the plague question in India. Their report favoured inoculation, opposed the enforced removal of plague patients to hospitals, which had proved the cause of much rioting and violence; and made other suggestions of which the sense generally was unfavourable to segregation, or evacuation of infected places except in villages and small towns, and to cordons, and the search of railway passengers. Again, in 1900, famine appeared and proved itself most severe in Bombay, Rajputana, and the Central Provinces. The tract concerned contained a population of 85 millions, of whom perhaps 52 millions were severely affected. Of the 85 millions, 43¼ millions were inhabitants of native states, and 41¾ millions were in British territory. At the close of May 1900, 5,802,000 were in receipt of relief. After the rainy season of 1900 distress gradually abated. The expenditure necessary to cope with the famine was estimated at £13,000,000 (at 15 rupees to the £1). The death of adults from starvation is stated to have been of rare occurrence, and due entirely to the apathy of the people themselves.

Finance and plague.

Attention may now be turned to the course of finance, and to the disturbing influences to which, successively or simultaneously, it was submitted from 1885 to 1900. In 1884, while the Government of India was engaged in the consideration of the projected extension of its railway system, an agreement had been arrived at between her Majesty's Government and the Government of Russia for the employment of a joint commission to delimit the frontier between the Russian dominions in Central Asia and Northern Afghanistan. Towards the close of that year the respective commissioners had met and commenced operations. In the spring of the ensuing year a collision took place between Russian and Afghan troops owing to claims put forward on either side to the occupation of the district and village of Panjdeh, lying within the disputed frontier zone. The work of the commission was temporarily suspended, and for some weeks it appeared probable that war would be declared between Great Britain and Russia. The difficulty was, however, arranged, and delimitation of the entire frontier ultimately effected. But the incident led to steps being taken by the Government of Lord Dufferin, with the view of strengthening the military system of India, which have had far-reaching effects on Indian finance. In August 1885 the Government of India (two members of the Viceroy's council dissenting) proposed an increase in the strength of the army in India, amounting to 10,657 British troops and 16,540 to the native army, with other changes, of which the result would be an estimated increased annual charge of about £1,500,000. These proposals were approved by the Secretary of State, and immediate measures were taken to carry them into effect. Projects for strengthening the defences of India, whether on its north-western frontier or on its seaboard, were also taken into prompt consideration. A scheme of frontier railways was elaborated, and a vigorous commencement was at once made in the direction of the Khojak tunnel, in the great Amran range, and on the approaches to Kandahar from the British side, and from the direction of Quetta. While clouds were gathering over the finances and internal progress of the country in this direction, a somewhat sudden and abrupt termination to a dispute between the Government of India and King Thibaw of Burma was brought about by the outbreak of war with Burma in 1885. For the causes of the dispute with the Government of Burma, and a description of the military operations which ensued after the deposition of King Thibaw before the country was finally pacified, the reader may be referred to the article on BURMA. The financial results only will be noted in the course of this article. For the present, it will be sufficient to say that the first-fruits of political complications and military measures, combined with a further fall in the exchange, was the repeal of the then existing licence tax and the reimposition of an income tax in March 1886; this being the first of a succession of fiscal measures by which in the course of the ensuing eight years the work of Sir John Strachey and Sir Evelyn Baring was gradually but completely undone, and the country again subjected to methods of taxation which it had been the object of their reforms finally to remove. The principal provisions of the income tax, as reimposed, were and are (for the tax has remained in force since its enactment in 1886) that incomes should be estimated under one or other of certain classified grades; that incomes amounting to Rs.2000 per annum should pay 5 pie in the rupee (2·6 per cent.), and if less than Rs.2000, 4 pie in the rupee (about 2 per cent.). All

Financial changes.

incomes of less than Rs.500 in the year are exempted, and the tax is not levied on agricultural profits, or incomes, or on military salaries of less than Rs.500 *per mensem.* The tax produced in the first year of its assessment £1,369,000, and has since risen in round figures to £1,800,000.

In introducing the Income Tax Bill in 1886, the financial member of the council had said: "With the present year our brief spell of happiness has come to an end. The fat kine have passed on, and the lean kine have come in. . . . Three uninterrupted years of prosperity is a godsend in the annals of every nation; in our Indian annals it is extraordinarily good fortune." In 1885–86 the fall in exchange which had been temporarily suspended recommenced, and the Burma war broke out. In 1886 India definitely entered into the region of depression and storm from war, famine, pestilence, and exchange, from which in 1902 she had not yet emerged.

The following paragraphs show the accumulation of difficulties during the years 1896 to 1900, and the measures taken to meet them:—

In 1881–82 the net sterling expenditure had amounted to	£14,029,700
The average rate at which remittances were effected was	d.19·815
The total charge for exchange was . .	£2,985,500
In 1886 the net sterling expenditure was .	£14,172,300
The average rate at which remittances were effected was	d.17·441
The total charge for exchange was . .	£5,631,800

An increase of £2,646,300 had thus been charged to the Indian revenues in five years, mainly by a fall of 2½d. in the exchange, as the net sterling expenditure had but little increased.

The following table shows the progressive charge on account of exchange from 1881–82 to 1899–1900, the last two years being estimates:—

Year.	Net Sterling Expenditure	Average Rate.	Exchange on Net Sterling Expenditure.	Total Charge for Exchange.
	£	d.	£	£
1881–82	14,029,700	19·895	2,894,300	2,985,500
1882–83	13,692,200	19·525	3,140,900	3,205,500
1883–84	14,764,100	19·536	3,373,700	3,358,900
1884–85	13,844,000	19·308	3,364,000	3,535,900
1885–86	13,755,700	18·294	4,329,900	4,289,800
1886–87	14,172,300	17·441	5,329,700	5,631,800
1887–88	15,128,000	16·898	6,356,900	6,049,300
1888–89	14,652,600	16·379	6,817,600	6,383,100
1889–90	14,513,200	16·566	6,512,800	6,758,000
1890–91	15,176,900	18·090	4,959,000	5,468,000
1891–92	15,716,800	16·733	6,825,200	7,200,900
1892–93	16,114,300	14·985	9,694,800	10,287,300
1893–94	15,633,400	14·547	10,159,600	11,523,400
1894–95	15,504,000	13·101	12,899,100	15,045,000
1895–96	15,380,000	13·638	11,685,200	13,990,900
1896–97	15,468,700	14·451	10,222,200	12,116,400
1897–98	16,004,600	15·354	9,012,500	10,562,300
1898–99	16,091,200	16·00	8,045,600	9,253,600
1899-1900	16,324,500	15·750	8,550,900	9,686,500

The reason of the difference between columns 4 and 5 is that in the latter are included additional payments to European soldiers on account of exchange from 1883–84 onwards, and exchange compensation to officers from 1893–94. It will be seen that from 1881–82 to 1884–85 exchange remained fairly stationary. In 1885–86 there was a fall of more than 1d., another fall in 1886–87, and again in 1887–88, when a pause ensued till 1890-91, in which year there was a marked temporary rise, due to legislation in America. In 1891–92 the exchange again fell, and continued to fall till 1894–95, when it reached its lowest point, viz., 13·101, the total charge for exchange amounting in that year to £15,045,000. In 1893 the Indian mints were closed to the coining of silver, with little immediate effect on exchange. In 1898 a gold standard was adopted, the sovereign was made legal tender in India, and interchangeable at the rate of one sovereign for fifteen rupees. From that time the exchange has remained comparatively steady.

Taking the average net expenditure of the years 1883–85, and contrasting it with 1895–96, the Indian expenditure commission found that the increase in the later period amounted to 12½ millions, thus:—

	India.	England.	Exchange.	Total.
	£	£	£	£
Defence and Foreign Affairs .	5,747,000	-201,000	4,240,000	9,786,000
Civil Charges .	1,637,000	238,000	1,415,000	3,290,000
Interest on Debt .	-2,073,000	112,000	1,393,000	-568,000[1]
Railways and Irrigation . . .	-4,371,000	922,000	3,341,000	-108,000
	940,000	1,071,000	10,389,000	12,400,000

[1] In 1888, 53½ millions of sterling 4 per cent. debt were converted into 3½ stock, securing a reduction of £266,000 annually. In 1894, 90 millions of rupee 4 per cent. debt was similarly converted, causing a saving of Rx.450,000.

To meet the increased expenditure it had therefore become necessary that the resources of the Indian treasury should be increased by about £12,000,000. This was effected over the term of years 1886 to 1894 as follows (the figures taken here are those furnished by the Indian expenditure commission report):—

Income Tax .	. £1,319,000	April 1886, licence duty repealed and income tax imposed.
Salt Tax .	. 1,500,000	Duty raised in 1888 from 2 to 2/8 per maund.
Customs .	. 2,750,000	In 1894 the 5 per cent. *ad valorem* duties of customs repealed in 1882 were reimposed, cotton goods being exempted, and a further import duty was put on petroleum. In 1895 the 5 per cent. import duty was extended to cotton, and an excise duty was imposed on Indian cotton mills.
Excise . . .	. 1,000,000	Estimated by Indian expenditure commission to be due to increase of taxation.
Patwári (village accountant) cess .	242,000	Repealed in 1882 by Sir E. Baring, but reimposed in 1888.
	£6,811,000	

Normal growth of net revenue .	£5,800,000
Add new taxation .	6,811,000
Total .	£12,611,000

Thus the taxation on salt and imports, which was abolished by Sir John Strachey and Sir E. Baring, has now been reimposed, and remains in force. Other taxation has been added; apart from the taxes above enumerated, countervailing duties were in 1899 imposed on bounty-fed beet sugar. The normal growth of revenue during the period of comparison (£5,800,000) was absorbed by the increase of expenditure under "defence and foreign affairs"—in other words, military and political—in India, and apart from the charge for exchange.

Of the total increased expenditure of £12,400,000, not less than £9,786,000, inclusive of exchange, was due to military and political expenditure. Inclusive of exchange, but exclusive of military works and minor charges, the net army expenditure is stated by the Indian expenditure commission to have risen from £16,147,000 in 1884–85, which was the last year before the increase in the army and the resumption of military activity, to £23,202,000 in 1896–97, an increase of 44 per cent. But this was only the increased charge on account of military expenditure of a permanent character. From 1886 onwards, with but brief intervals, there has occurred a series of wars and frontier expeditions, some of which, such as the Burmese war of 1886–87, were extremely costly. The preparation for possible war with Russia amounted, in 1885–86, to over two millions. The war with Burma cost, in the three years 1885–86 to 1887–88, over four millions. Minor expeditions, from 1887–88 to 1895–96, cost over five millions. The Tirah campaign of 1897–98 (though this was of a date later than 1896-97, the last year of the commission's comparison) cost over three millions —say in all, in round numbers, fourteen millions in eleven years. Increase in military and political expenditure, and increased loss by exchange (itself partly caused by the increase in military expenditure), are the causes which have led to the reimposition of the customs duties on cotton and other goods, and to the raising of the salt duties. The increased loss by exchange has been checked by closing the Indian mints to the coinage of silver and by the adoption of a gold standard. The further increase of military and political expenditure must largely depend on the policy

pursued by the Government of India with regard to the tribes on its north-western frontier, and to the course of events hereafter in Afghanistan.

From 1880-81 to 1899-1900 the following have been the years respectively of surplus and deficit, and the chief causes of increase or decrease in the revenues are indicated in the final column :—

Year.	Surplus.	Deficit.	Remarks.
	£	£	
1880-81	...	4,044,000	Afghan war.
1881-82	2,582,727	...	Financial effect of Sir John Strachey's reforms.
1882-83	706,633	...	Customs duties abolished, Salt duty lowered.
1883-84	1,879,707		
1884-85	...	386,446	
1885-86	...	2,891,726	Russian war scare; commencement of Burma war; fresh fall in exchange.
1886-87	178,427	...	Income tax imposed, and Burma war.
1887-88	...	2,028,832	Burma war and civil charges; continuous fall in exchange.
1888-89	37,018	...	Salt duty raised.
1889-90	2,612,033		
1890-91	3,688,171	...	American silver legislation.
1891-92	467,525		
1892-93	...	833,410	Heavy fall in exchange.
1893-94	...	1,546,998	Exchange compensation first granted to officers.
1894-95	693,110	...	Customs and cotton duties reimposed during year.
1895-96	1,533,098		
1896-97	...	1,705,022	War and famine.
1897-98	...	5,359,211	War.
1898-99	3,961,310	...	Gold standard adopted.
1899-1900	4,059,400		
Total .	22,399,159	18,795,645	

In 1882-83, the year in which the customs and salt duties were removed, the gross revenue was £70,125,231, and the gross expenditure was £69,418,598. In 1898-99, the year in which the finances were restored to order by the adoption of a gold standard, the gross revenue was £101,426,693, the gross expenditure was £97,465,383. From 1881-82 to 1899-1900, £6,350,000 are estimated as having been spent from the famine insurance grant—in other words, from current revenue—in reduction or avoidance of debt. On the other hand, in comparing surplus and deficit, it must be remembered that between 1886 and 1894 taxation yielding annually since the latter date £6,800,000 has been at different times reimposed. If we remove on the one hand the deficit of 1880-81, as due to the Afghan war, and on the other the surplus of 1898-99 and 1899-1900, as due to improvement in exchange following on the adoption of a gold standard, we have for the remaining seventeen years practically equilibrium. But this equilibrium is entirely due to the taxation imposed since 1886. It is probable that the necessity of accumulating a large gold reserve will compel the Government of India to maintain for a time much of this taxation which might otherwise have come under reduction.

The position therefore is this: The total charge on account of exchange remains, and is likely to remain, steady unless the Secretary of State increases his drawings. We may on the present revenues reckon on a surplus of revenue over expenditure of not less than four millions, in the absence of war and famine. But there remain on the taxation roll import duties and enhanced salt duties, yielding collectively about four millions annually, which have been unreservedly condemned by the highest financial authorities in India, as permanent sources of revenue, and which were removed in 1878 and subsequent years. The surplus of revenue over expenditure, viz., £4,000,000, and the proceeds of these taxes balance one another, leaving the finances in bare equilibrium, with the prospect, on the one hand, of an annual addition say of £500,000 from normal expansion of revenue, against which, on the other hand, will be debited corresponding annual growth in expenditure.

Reference has been frequently made in these pages to the royal commission on the administration of the expenditure of India. This commission was appointed in 1895 "to inquire into the administration and management of the military and civil expenditure incurred under the authority of the Secretary of State for India in council and of the Government of India, and the apportionment of charges between the Governments of the United Kingdom and of India for purposes in which both are interested." The commission presented in 1900 an exhaustive and very valuable report, dealing, however, with revenue and expenditure up to 1895-96 only, between which date and 1900 there had occurred two famines, two or three very costly frontier expeditions, and the very important currency legislation of 1898, so that by 1900 the course of events had already discounted much of the value of the commission's conclusions. The report, nevertheless, presents an exhaustive study of the financial mechanism of the Indian Government, with a careful, if somewhat favourable, review of the progress of its revenues and expenditure from 1862 to 1895-96. It also deals with the apportionment of charges between England and India in respect of army and naval and certain civil and miscellaneous charges, and recommends grants to the annual amount of £230,000 from the Imperial Government to the Government of India being as follows :—In aid of the charge for the India Office (£50,000), one-half of the military charges for Aden (£108,000), increased contribution to the charge of the Persian mission (£5000), half the cost of transport of troops to and from India (£130,000).

Currency difficulties.

Some account must here be given of the measures successively adopted by the Secretary of State for India for the reform of Indian currency by the closing of the Indian mints and the adoption of a gold standard. In 1892 Indian representatives were sent to the International Monetary Conference at Brussels, which was convened for the consideration of measures for the increased use of silver as money. The Government of India in June 1892 proposed that, should the conference fail to arrive at a satisfactory conclusion, it should at once close its own mints to the free coinage of silver and make arrangements for the introduction of a gold standard. Its proposals were submitted by the Secretary of State to a committee in October 1892, which in May of the ensuing year reported that they could not oppose the proposals of the Government of India as to closing the mints against the free coinage of silver, but recommended that they should be accompanied by an announcement that, though closed to the public, the mints should be used by the Government for the coinage of rupees in exchange for gold at a rate to be then fixed, say 1s. 4d. per rupee, and that at the Government treasury gold would be received in satisfaction of public dues at the same rate. The committee's recommendations having been approved by the Imperial and Indian Governments, an Act was passed on the 26th June 1893 for the closing of the Indian mints to the free coinage of both gold and silver. Arrangements were at the same time made for the receipt of gold at the Indian mints in exchange for rupees at the rate of 16d. per rupee; for the receipt of sovereigns and half-sovereigns in payment of sums due to the Government at the rate of 15 rupees for a sovereign; and for the issue of currency notes in exchange for British gold at the above rates, or for gold bullion at a corresponding rate. Gold, therefore, was not made a legal tender in India in pursuance of these arrangements, though the Government was prepared to receive it in payment of public dues.

The rupee remained by law the only coin in which other than small payments could be made; no legal relation was established between rupee and gold, but the Government of India declared (until further notice) the rate at which rupees could be purchased for gold or bullion. In 1893-94 the average rate per rupee at which council bills and telegraphic transfers were sold in London was 14·547d.; in 1894-95 the exchange fell to 13·101d.; in 1895-96 it was 13·638d.; in 1896-97 it had risen to 14·491d.; and in 1897-98 it reached 15·354d. The effect of closing the mints in 1893 thus first began to make itself distinctly felt in 1896-97.

In 1898 the Government of India made further proposals with the view of keeping the exchange value of the rupee at a steady level of 16d. These proposals were, in their turn, submitted in April of that year to a mixed committee, which reported in July 1899. The recommendations of the committee were :—

(1) That the British sovereign should be made a legal tender and a current coin in India.

(2) That the Indian mints should be thrown open to the unrestricted coinage of gold on terms and conditions such as govern the three Australian branches of the royal mint.

(3) That no legal obligation should be imposed on the Government of India to give gold for rupees, or, in other words, to substitute the former for the latter on demand of the holders.

But though there should not be convertibility on demand, gold should be freely available for foreign remittances whenever the exchange fell below specie point. The Government of India should make its gold available for this purpose, when necessary, under such conditions as the circumstances of the time might render desirable. The exclusive right to coin fresh rupees should remain vested in the Government of India. Though the existing stock of rupees might suffice for some time, regulations would hereafter be needed for providing such addition to the silver currency as might prove necessary.

The fixed permanent relation which the rupee should bear to the sovereign should be 1s. 4d.

Legislative effect was given to these proposals in September 1899, and the currency system of India is at present arranged in conformity with them. The time has not come when the success of the measure adopted can be confidently affirmed, whether as regards the Government or the course of trade. While the experiment is viewed with distrust by the majority of export traders, it has been uncompromisingly condemned by the authority of Sir Robert Giffen. Writing in 1898 to *The Times* (19th May 1898), Sir Robert expressed his belief that the attempt to introduce a gold standard in a poor country like India must fail; that gold to the amount of £90,000,000 at least should be accumulated beforehand; and that the Indian Government could not bear the expense. On the other hand, in his financial statement for 1900–1901, the financial member of council stated that before the beginning of 1899–1900 the Government had added 305 lakhs from the reserve to the volume of silver in circulation in exchange for gold presented to them. During the year 1899–1900 they had added 776 lakhs (a lakh is equal to Rs.100,000) in exchange for gold presented in India, and 225 lakhs in exchange for gold presented in England, a total for the year of 10 crores (1 crore is equal to one million rupees). To enable the Government to make these additions they had coined $1\frac{1}{2}$ crores of new rupees, and had decided on supplementary coinage to the extent of 1 crore, a total of $2\frac{1}{2}$ crores. The position in respect of gold was strong. In India and in London nearly £8,600,000 had been accumulated. £5,000,000 had been set aside for the present as a minimum reserve against eventualities, against the contingency of the Secretary of State's being obliged to restrict or curtail his drawings or to ask the Government of India to ship home gold to enable him to meet his obligations. Gold was coming in in large quantities. There was no appearance of any falling off of the export trade owing to the adoption of a gold standard, or gold currency convertible at 1s. 4d.

The statistics of trade are given elsewhere. Of the three great industries introduced by British capital into India, two are unhappily at the present moment in a state of singular depression, and one is in chronic insecurity. Tea is suffering from the effects of over-production and the placing of inferior teas on the European market. The cotton-spinning industry has been depressed owing to keen competition from China and Japan, and unfavourable seasons for the purchase of cheap cotton. Indigo, though not depressed, is continuously threatened with competition, and possible extinction, by the introduction and perfecting of chemical dyes.

Events on the north-west frontier.

Since 1889 India has suffered from a succession of frontier wars. At the close of the Kabul war in 1880 the British Cabinet decided to withdraw not from Kabul only, but from Kandahar. The policy of the Government of that day is fully stated in the two despatches of the Marquis of Hartington (afterwards Duke of Devonshire), respectively dated 21st May and 11th November 1880 (to be found in the Afghanistan Blue Book, No. 1 of 1881). Events were shaped accordingly; and with the exception chiefly of the Pishin and Sibi districts, and of Quetta, the British retired within their former borders. So matters remained till 1883–84, when the advance of Russia in Central Asia again turned the attention of the Government of India to affairs on and beyond the frontier, and led ultimately to the final abandonment of the policy of observation and reserve, which is known as the Lawrence policy. The control of the frontier was transferred in the latter part of the eighth decade from the Lieutenant-Governor of the Punjab to the Government of India in its foreign department. From that time the policy of non-interference was replaced by increasing activity. From 1885, when war with Russia seemed imminent, there has been more or less (less from 1885 to 1889, and in later years far more) continuous movement along one or other part of the frontier and beyond the British border, indicating the gradual development of a prearranged plan of operations. Between the years 1885–95 there were delimited at various times by joint commissions the Russo-Afghan frontier between the Oxus and Sarakhs on the Persian frontier, the Russo-Afghan frontier from Lake Victoria to the frontier of China, and the Afghan-Indian frontier from the Kunar river to a point in the neighbourhood of the Nawa Kotal. To the westward, after various disagreements and two military expeditions, the territories comprising the Zhob, Barhan, and Bori valleys, occupied by Pathan tribes, were in 1890 finally incorporated in the general system of the Trans-Indus protectorate. About the same time (in 1889) at the other end of the frontier, where it touches China, the post of British resident in Gilgit had been re-established. The result became very shortly apparent. The government of Kashmir having for the time passed under the direct control of the British authorities through the death of the Maharaja in 1889, a council of regency was established under the supreme direction and authority of the British resident in Kashmir. Acting under his instructions, the Council asserted and, with the aid of its troops led by the Resident of Gilgit and by other British officers, re-established its supremacy over the petty states of Hunza and Nagar, in the neighbourhood of Gilgit, which it claimed as feudatories. The former chieftains were deposed, and others, more friendly to the British Government, replaced them. In 1893 the frontiers of Afghanistan and British India were defined by a joint agreement between the two Governments. There followed, on the part of the British authorities, interference in Chitral, which had fallen to India, ending in an expedition in 1895 and the ejection of the local chiefs in favour of candidates amenable to British influence. A more formidable hostile combination, however, awaited the Government of India. By the agreement of 1893 with the Amir most of the Waziri clan, the Bajouris, and the Afridis had been left outside the limits of the Amir's influence and transferred to the British zone. Soon after that date the establishment by the British military authorities of posts within the Waziri country had led to apprehension on the part of the local tribesmen. In 1895 the occupation of points within the Swat territory for the safety of the road from India to Chitral similarly roused the suspicion of the Swatis. The Waziris and Swatis successively rose in arms, in June and July 1897, and their example was followed by the Mohmands. Finally, in August the

powerful Afridi tribe joined the combination and closed the Khyber Pass, which runs through their territory, and which was held by them, on conditions, in trust for the Government of India. This led to the military operations known as the Tirah campaign, which proved very costly both in men and money. It was not till February 1898 that hostilities finally ceased along the border, with a total British loss in all the several engagements with the several tribes of 506 of all ranks killed, 537 dead of disease, 1428 wounded, and 9 missing—in all 2480. By the middle of 1898 British authority had been made paramount throughout the whole belt of territory which stretches between the former British frontier and the frontiers of Russia and Afghanistan, and from the Karakoram Pass to Pishin.

These campaigns on the frontiers occurred at a time of great difficulty, when, owing to increasing loss by exchange, and latterly to famine and plague, the resources of India were subjected to excessive strain. Public attention in the United Kingdom was consequently much engaged upon the whole question of Indian frontier policy; and it was very generally felt that of late years the Government of India had been permitted to embark in a course of aggression and adventure on its frontier for which no adequate necessity could be shown to have existed. From 1890 to 1898 many millions were spent in asserting British supremacy over the territories brought within what is sometimes known as its "political frontier." The active exercise of such supremacy still remains, however, in abeyance. The tribes to be dealt with are noted for their lawlessness, treachery, and violence, even among Afghan tribes. It is to be hoped that they may gradually allow themselves to be peacefully incorporated within the system of British India. However this may be, considerable increase of expenditure must be anticipated as a result of the new departure. At the best, roads must be constructed, military levies must be raised and paid, and some efforts must be encouraged to introduce among the tribesmen the elementary institutions of civilization.

Other smaller frontier expeditions were undertaken by the Government of India in the Hazara country on the north-west frontier in 1888–89 and 1891–92, in Sikkim in 1888–89, in Miranzai in 1891–92, and in Manipur in 1891–92. But these entailed comparatively little expenditure (about one million in all); they were isolated and apart from any general plan of frontier policy, and have been productive of no great increase of permanent expenditure.

The main incidents of the course of events within British India since 1880 have now been briefly reviewed. Much of interest has of necessity been omitted. But it is hoped that a general idea may have been conveyed of their tendency and progress. It has been seen that the state barometer, which stood at its highest in 1881 and 1882, began again to fall in 1885, and passing rapidly from that year through periods of violent disturbance, remained at its lowest from 1892 to 1899. Since 1899 there are signs of more settled conditions, and it may be that before long India will have returned to the brighter promise of 1881. If war, famine, and exchange no longer deplete the treasury, more funds may be forthcoming from the proceeds of taxation to meet the pressing civil needs of the taxpayer, such as sanitation, education, better remuneration to subordinate officials, a higher-paid and better-conducted police force, good feeder roads—in short, the many internal requirements for which little consideration has been available in recent years of stress. The promotion of the internal prosperity of India is, by common consent of all parties, the main obligation which rests on its Government; and to secure this it is above all necessary that the administration should have the leisure, the will, and the means to provide the conditions most favourable to such an end. Prolonged peace and comparative freedom from fiscal burdens are among the most important of such conditions. There seems some ground for now hoping that the difficulties caused of later years by the burden of exchange have been at least restricted within practical limits. But famine is ever a probable danger; and political and military ambitions, with the complications attendant on them, have always to be reckoned with.

Summary 1880-1901.

Viceroys, 1880-1901.

The Viceroys who held office during the period here dealt with were the Marquess of Ripon, 1880–84; the Marquess of Dufferin and Ava, 1884–88; the Marquess of Lansdowne, 1888–95; the Earl of Elgin, 1895–99; Baron Curzon of Kedleston, 1899. Few of his predecessors in the government of India were animated by greater zeal, or sustained by a higher conception of duty, than Lord Ripon. In the prime of life, possessed of much ability, an indefatigable worker, and of experience in public affairs, he was greeted on arrival in India with a welcome the more warm in that the public had grown distrustful of his predecessor. Before he laid down office the goodwill with which he had been received had turned into hatred such as had never before dogged the footsteps of an Indian Governor-General. So long as Lord Ripon confined himself to raising and improving the status of the native of India his action was followed by the British community, if not with warm approval, at least with kindly goodwill. But when he proceeded to assimilate the authority of native magistrates over European British subjects to that of British magistrates themselves, he was rudely made to feel that the Government of India, autocratic though it may at times be with the natives, must be more circumspect in dealing with the British community. The struggle with his fellow-countrymen in which Lord Ripon suffered himself to be involved dealt a death-blow to his usefulness as Viceroy. Instead of holding the balance between all parties, the Viceroy became seemingly a partisan of one against another. When Lord Ripon's name grew to be a symbol between contending factions, nothing remained for him but to withdraw from an office in which he could no longer render useful service. But the Indian historian will hereafter record that to Lord Ripon belongs the distinction of having been the first Viceroy openly to recognize and give practical encouragement to the growth of a self-respecting spirit of endeavour and of the desire for some measure of self-government among the more advanced classes of the natives. He sought, as events have shown not unsuccessfully, to assist them in raising themselves from an attitude of passive administrative subjection to a position more worthy both of themselves and of the Government under whose liberal rule they live. His generous and kindly recognition of their claims and capacity was warmly responded to by all classes of natives; and if he was condemned to leave Calcutta in whatever disgrace may be thought to attach to the censure of that city, he received from the natives of India throughout his journey to Bombay a spontaneous and enthusiastic ovation, of which the like has never been accorded to his predecessors or successors. It is greatly to the honour of Lord Dufferin that, though by no means indifferent to popularity among his countrymen, he never for a moment hesitated to continue and to carry farther the main lines of the enlightened policy which had been initiated by Lord Ripon. But in Lord Dufferin's sagacious hands the rocks and shoals on which his predecessor foundered were avoided. In raising the

status of the native civil service, and in enlarging the basis and extending the attributes of the several legislative councils, Lord Dufferin laid the native population under a lasting debt of gratitude. In the historic interview with the Amir of Afghanistan in 1885 at Rawalpindi, as throughout his treatment of the Panjdeh incident, his characteristic firmness and suavity were equally displayed. His term of office was darkened by financial difficulties, largely owing to the fall in exchange. The conquest of Upper Burma, though it increased his popularity and added to the lustre of his Viceroyalty, reopened the floodgates of military expenditure and added to financial troubles. He maintained throughout his term of office a high standard of administration, while his personal charm of manner, his tact, his hospitality, his wit and genial humour, secured for him universally the affection of his countrymen. With the advent of Lord Lansdowne the liberal policy of his immediate predecessors suffered eclipse. Lord Lansdowne's urbanity and high distinction conciliated and impressed all with whom he was brought into personal contact. But, as time passed, it became evident that his thoughts were more occupied with affairs beyond the north-west frontier of India than with the interests of good government within its limits. The growing influence exercised over the Viceroy by his chief military and political advisers became more and more matter of uneasy comment. Under their influence, and probably with approval in Whitehall, Lord Lansdowne renewed in substance Lord Lytton's policy, and the wars which have drained India of money and men since 1896 were due to the course of action adopted under his auspices in the years preceding. There never was a time since 1838 when Simla was so actively the centre of ambitions, and of designs beyond the Indus. The most favoured type of Indian official was no longer the provincial governor or the sagacious resident, but that warden of the marches of Baluchistan, Sir Robert Sandeman, whose unique aim it was to extend the zone of British influence beyond the frontier, and whose method was to participate in tribal dissensions, and to profit by them. "Sandemania," which has proved so contagious, then first became epidemic in high quarters. It should be added, however, to the credit of his administration, that Lord Lansdowne grappled successfully with one hideous evil in Hindu social life, which required all the more courage to combat because it rested on immemorial custom, and was hallowed by religious sanction. He left behind him an Act to raise the age of consent among Indian wives from ten to twelve, which, while it provoked much popular clamour, was approved by men of enlightenment of all creeds and races. During so much of his term of office as was not occupied with combating famine and plague, Lord Elgin was engaged in conflict beyond the frontier with enemies who were none of his own seeking, or in acrid controversy with political friends in England on questions arising out of the political difficulties which had been bequeathed to him by his predecessor. Though the credit of introducing a gold standard into India does not personally rest with Lord Elgin, it was during his term of office that the measure was matured and effect given to it. Of Lord Curzon it is premature to speak. But his frontier policy would seem to be conciliatory and judicious, and to be framed with that regard for economy which of late years has been conspicuously absent. The creation of a border province beyond the Indus under a separate head (the North-West District), which was accomplished in 1901, would have been, when Lord Lytton first proposed it, premature. At that time, when the frontier was as yet undefined, and when the relations of the tribes with the British and Afghan Governments, and of those Governments with one another, were unsettled, the measure would certainly have provoked collision, especially if a successful and ambitious soldier had been selected to be chief of the proposed province. As matters now are, the arrangement may be regarded with more satisfaction.

Towards the latter years of the 19th century the last of the old Haileybury civilians, who entered the service as nominees of the East India Company's directors under the system abolished in 1857, were leaving India. For thirty years or so they had been contemporaries and rivals of their brethren who had been recruited since 1856 by the present rule of open competition. It is noticeable that, towards the close of their term of corporate existence, most of the highest offices available in India to the civilian were held by Haileybury men. The public works and financial members of the Viceroy's council, with the Lieutenant-Governor of the Punjab, the North-West Provinces, and Bengal, were in 1887 all nominees of the East India Company. While none will regret the demise of the system of nomination, the fact shows that with much rubbish it furnished also useful material. It may interest Etonians to find that in 1890–91 the Viceroy (Lord Lansdowne), the Commander-in-Chief (Lord Roberts), the Governor of Madras (Lord Wenlock), the Lieutenant-Governor of Bengal (Sir Steuart Bayley), the Lieutenant-Governor of the North-West Provinces (Sir Auckland Colvin), and the Lieutenant-Governor of the Punjab (Sir James Lyall) were all old Etonians.

Anglo-Indian relations.

In the course of the debate in the House of Commons on the Indian budget of 1900–1, Lord George Hamilton observed that he sometimes doubted whether, in spite of all their labours, the popularity of the British in India had increased. The substitution of a mechanical for a patriarchal system of rule seemed to the Secretary of State for India to lie at the bottom of any loss of popularity which might have occurred. To observers who have better opportunities of personally judging than the Secretary of State, there seems no good reason for believing that British unpopularity has increased among the Indian masses. They are as amenable as of old to British officers, they consult them as freely, they crowd to their camps when on tour, and are as friendly in intercourse and bearing as in former times. It is in the so-called "educated classes," the outcome of Western education, that goodwill is less apparent. The native educated by English methods looks on himself and his countrymen as unduly debarred from many prizes offered to his British fellow-subjects, and keenly resents the social ostracism to which he is too frequently subjected. He has command of a press, both English and vernacular, which vividly reflects his discontent, and therefore suggests the existence of more widespread disaffection than in truth exists. By these and similar methods he seems to possess more influence than he really wields, and he labours to have it appear that the dissatisfaction which he personally feels is generally shared by his fellows. Then again the glamour of success, the mesmeric fascination, the *ikbál* (to use an expressive Arabic word in familiar Indian use), the star, as Napoleon would have said, which did so much for British influence in an earlier day, when no one knew much about the new rule, but every one saw that it was irresistible, has greatly died away. The nature, the defects, the limitations, and the difficulties of British rule are now matter of more analysis and speculation. Familiarity has produced something of its proverbial effect, and there is little in the present social relations between the races to bring the critics and the criticized on to a footing of more mutual goodwill. The levelling tendency of British rule again is abominable to the powerful classes which have hitherto monopolized authority. The "new man," viewed as a type of humanity, is often but a poor creature compared with many of those whose influence he is displacing. The dislike which attaches to his ascendancy is passed on to

the Government which has created him. As the new man is himself foremost in censuring and in criticizing British authorities, the Government meets on either side with disfavour. Finally, outside of all this, there arise from time to time special causes of dissatisfaction. In Bombay and in the North-West Provinces the population has rebelled against restrictive measures which were thought necessary to prevent the spread of plague. As the plague commission has also pronounced against many of these measures, it is much to be regretted that resort should have been had to them. There is little that the native of India will not submit to in the way of arbitrary exaction or injustice, but the Government which violates the privacy of his hearth will infallibly rouse him to fury. Little has happened at Bombay and in the North-West but what men of experience must have expected. The memory of that painful time will long rankle in the hearts of those who have survived it. Nothing has hitherto lent more strength to the British Government than its invariable regard for the sanctity of domestic life and for the free exercise of religious faith. One of these bulwarks has been seen momentarily to crumble, and it is to be hoped that the administration, which has now hastened to retrace its steps, will remain within the limits of its former policy. The curious demonstrations against cow-killing which occurred in recent years in parts of the North-West Provinces are more obscure in origin. But it may be conjectured that the zealots of the Hindu faith do not witness without emotion the widespread sapping of their creed which is everywhere obvious, or harbour towards the Government with which they connect it any feeling except that of hatred.

Personalia. During the years 1880–1900 various figures have flitted across the Indian stage and have come more or less into notice. Of such, among the British, was Mr Allan Hume, the sponsor of the Congress, a retired Indian civilian. The late Sir George Allen left India in recent years, after a lifetime spent in maturing and bringing to a successful issue various useful industrial enterprises. Sir George Chesney, whose comparatively early death is greatly to be deplored, took with him to Parliament, where he represented the city of Oxford, the prestige of his career and some remembrance of his literary successes. Sir William Hunter, also too soon summoned away, employed his pleasant and instructive pen in familiarizing the general public in England with the history and circumstances of their great dependency; Sir Alfred Lyall strengthened his reputation as an original thinker on Indian and Asiatic problems. The Stracheys published their important volume on the *Finance and Public Works of India.* Mr Crooke and Mr Grierson explored the folklore, the dialects, and the rural customs of the North-West Provinces and Behar; Mr Growse wrote on Hindu architecture and archæology. The classical age of Anglo-India—the age, that is to say, of Warren Hastings—was brought before the eye of the present generation by Dr Busteed, in his charming *Echoes from Old Calcutta.* Mr Howell brought to a term the heavy labours of his *Arabic Grammar.* Mr Arnold, of the Anglo-Mahommedan College at Aligarh, took up the cudgels for the Mahommedan conquerors of past time in his *Preaching of Islam;* Mr. C. J. Lyall published an interesting volume of extracts translated from pre-Mahommedan Arabic poetry. But conspicuous among all has been the rise to fame in England of Mr Rudyard Kipling, whose earlier efforts, when they first appeared in the early 'eighties in India, were at once hailed with unanimous recognition. Regarded as pictures of society, his *Plain Tales from the Hills* were manifestly caricature. But as clever etchings of types and characters, and as brilliant sketches of lighter aspects of Anglo-Indian life, they were felt to be pertinent and truthful. The language in which they were written was by no means conspicuous for purity or refinement. But it served all the more to bring vividly home to its readers the scenes and the persons described; for it was served up smoking-hot from the mess, the cutchery, the assembly rooms, the gymkhana—from wherever, in a word, Anglo-Indians resort. When Mr Kipling passed on to other conquests in other lands, the good wishes of all whom he left behind in India accompanied him. But when presently it was found that his pen and ink sketches, which were taken quite seriously in England as pictures of daily social life in India, brought no little obloquy on its society, and when it was seen that the author was at no pains to put his readers right, Anglo-India somewhat faltered in its allegiance. His popularity, nevertheless, in India, as elsewhere, eclipses that of all other Anglo-Indian writers. Yet there is one whose memory his admirers would not willingly let die. Many recall, with singular pleasure, the gentle malice of Aberigh Mackay; nor would they hesitate to barter many chapters of the *Plain Tales* for the delicate vignettes, the sparkling epigrams, the keen but inoffensive banter, and the incisive word, in a single page of *Ali Baba.*

Among natives of India, Sir Madhava Rao and Sir Sayad Ahmad remained severally conspicuous among their Hindu and Mahommedan contemporaries for all that is most worthy and sincere in Indian aspiration and performance. Two Indian gentlemen, Mr Dadabhai Naoroji and Sir Mancherjee Bhownaggree, succeeded in gaining admission to the House of Commons in the Radical and Conservative interest respectively. H.R.H. the late Duke of Clarence and the Cesarewitch, afterwards the Tsar Nicolas, successively visited India in the early 'nineties. Various Indian princes, such as Holkar, Baroda, and Rampur, came to England. A host of minor Indian writers burst out from time to time into ephemeral life and activity, or were hatched in tropical heat of controversy. Mr Bahramji Malabari, author and reformer, continued, not without success, his great crusade against infant marriage and in favour of the re-marriage of Hindu widows. Intellectual struggle, increasing antagonism between old and new ideas, the growth of a corporate feeling of self-respect, a keen and fixed desire, therefore, among educated and enlightened men to be of more account in the affairs of their country, the weakening of old bonds, the sapping of old prejudices—to apply, in short, to a peninsula a simple but expressive metaphor from progress in another line—the "gradual getting up of steam"—are the great characteristics of the present day. From 1860 to 1900 what changes! what advance! Every year adds to the number of Indians who flock to British colleges or to the Inns of Court. The iron bands of caste, of custom, and of spiritual authority are more and more relaxing. The sanctions and the penalties by which Hindu society was regulated are gradually but surely falling into disuse, and as yet there is no new system to replace them. Slowly (and better therefore if slowly) an ancient creed is nodding to its fall. It is the story of the sleeping Princess. For long ages India has slumbered immovable, but at length the spell is broken. From the far West has come the awakening. Suddenly life is actively resumed. The parrots and the monkeys scold, the geese cackle, the ass brays, but man hurries anew about his business. Torpor is shaken off, and a nervous activity takes the place of silence and inaction. The Princess has arisen, and moves forward, though with dazed eyes and uncertain steps, encumbered by the folds of her old-world garments. In confidence, yet not without hesitation, she follows the stranger into a world which is new and unimaginable to

her. The dawn as she draws onward quickens all her pulses, and shines more and more upon her, as she advances, with the light of incomparable promise. (A. Co.)

The Native States.

The origin of the native states of India, and their political relations to the British empire, can only be explained historically by a reference to the condition of India in the middle of the 18th century. At the opening of that century the Moghal emperor was still formally supreme throughout, from the northern mountains almost everywhere to the sea; and the whole country was distributed into great provinces directly under imperial rule, except where petty chiefships survived which more or less acknowledged the Moghal supremacy and professed to be feudatories, or in districts that were openly defying the imperial governors. The strength and size of the chiefships, as of the districts in rebellion, varied in proportion to their distance from headquarters, to their accessibility, and to the vicissitudes of the imperial policy. In the wilder parts of India there were tribes that had never been effectively subdued, and there were chiefs in the highland tracts whose subordination to the Delhi Government had been merely nominal. On the western side the Marathas had raised, and were maintaining, a formidable insurrection. Yet it may be affirmed generally that from the Himalaya mountains to Cape Comorin no separate state existed that had established and openly asserted its independence or denied the imperial sovereignty. But after the death (in 1707) of Aurungzeb, the Moghal empire declined rapidly towards its fall, and within the next forty years it had subsided into complete dilapidation. Nadir Shah had crossed the north-western frontier of India in 1735, sacked Delhi, and extorted the cession of the emperor's western provinces along the Indus. The Afghans poured down from the north into the Punjab; the Marathas overspread the central region, and were pushing northwards and southwards; the great viceroyalty of the Dekhan had been converted into a rulership under the Nizams of Haidarabad; while in Bengal and Oudh there were military adventurers who governed in the emperor's name, but were actually carving out possessions for themselves. In that wide central region, which had been occupied for centuries by the Rajput clans, the chiefs kept up a precarious resistance against Marathas from the south and Mahommedans from the north. The map of the Moghal empire had thus been torn into pieces, and the whole territory was being parcelled out again into principalities which merely represented the fragments that rival potentates could seize and hold. If we set aside the group of ancient Rajput chiefships, every considerable native state that at the present moment exists in India traces its formation no farther back than to this epoch, and is ruled by some family whose founder won his lands in this period of universal confusion.

Historical origin.

Almost all the native states of India, therefore, represent the scattered remnants of those rulerships that were hastily built up out of the ruins of the Moghal empire, which had itself consolidated a number of pre-existent kingdoms. The whole Indian continent had fallen back into that condition of separate contending principalities, professing but not practising allegiance to an emperor at Delhi, which prevailed before Baber founded the Moghal dynasty in the early part of the 16th century. That dynasty had now succumbed; but it had hardly passed away before another empire began to take the vacant place, growing slowly at first and with almost imperceptible advances. The rise and progress of the British power, however, in no way followed the method of its predecessor; and this difference had an important effect upon the formation of the native states as we now see them. In the 16th century Baber conquered all northern India by force of arms, and his successors extended their dominion by a series of campaigns; they subdued all opposition by superiority in war. They left standing no rivals whom they could overthrow; their object was to bring the whole country under their yoke; they tolerated no equality; their monarchy was avowedly military and aggressive; their power levelled every obstacle that it could reach.

The British dominion began in another manner and went on by other methods. Englishmen had obtained their foothold on the Indian sea-coast as traders, and for some time afterwards they neither attempted nor desired territorial possessions. Their gradual interference in the quarrels and intrigues of the native princes was mainly forced upon them in their commercial competition with the French; and thus they entered upon a system of extending their sphere of influence by alliances with the nearest states, assisting them with troops and money, so that their general policy was to join any friendly power in resistance against a common enemy. When in 1757 Clive made for the East India Company their first substantial conquest of territory—the province of Bengal—he merely added one more to the long list of states, held nominally by a grant from the Delhi emperor but really independent, into which the old empire had been broken up piecemeal. And as the British dominion inevitably expanded by reason of its superior military strength and resources, this policy of alliances with friendly or needy potentates against hostile and jealous rivals was steadily preserved, sometimes with a view to a balance of powers, at other times in order to interpose a belt of protected states between the English border and formidable neighbours, and occasionally to unite in some offensive operation against a common foe. The East India Company extended their territory by cessions from their friends, taken in exchange for assistance, as well as by conquests from enemies; they received assignments of land as security for subsidies or for the payment of troops lent. At the end of a successful war they did not, at this period, utterly destroy their antagonist; they disabled him by annexing or distributing large portions of his territory, by disarming him, and sometimes by placing an English garrison with a diplomatic agent at or near his capital.

Extension of British control.

The policy of the East India Company, therefore, during the first period of their establishment in India had been to avoid aggrandizement and to fortify their position by alliances with the neighbouring states. They soon found themselves obliged by stress of circumstances to fight for their safety, and afterwards to contend for ascendency, as the only sure basis for maintaining themselves in the prevailing confusion and for securing the tranquillity of the country. They could not reduce their own troops while other armies were incessantly in the field. The course they adopted was to cut down the strength of their enemies, and gradually to assume control over the military forces and political relations of their allies, obtaining large accessions of territory by conquest and by cession. At the close of the 18th century there were only two native powers in contact with British possessions whose hostility was formidable—the Mahommedan dynasty in Mysore, and the group of Maratha chiefships. During the Governor-Generalship of Lord Wellesley (1798–1805) Tipu, sultan of Mysore, was defeated and slain, and the Maratha confederacy was broken up. Lord Wellesley introduced that system of subsidiary treaties which has played so important a part in the expansion of British dominion. His

policy was to extend the British protectorate over all the states with which Great Britain had then any concern, by insisting that each native ruler should reduce his army, and should rely for external defence upon the military power of the British Government. Each protected state was required to supply, not troops as formerly, but money, and the British Government undertook to raise, train, and pay a fixed number of troops in return for a subsidy, or for a cession of land yielding equivalent revenue, that would provide the cost of the troops furnished by the protecting authority.

But Lord Wellesley's policy, which aimed at the universal dominion of the English in India, and indeed laid its foundation, was discontinued for a time by his successors, who desired to free themselves from such extensive liabilities, and to be content with the defence of British territories, leaving the states beyond the frontier to fight out their own quarrels. The result was that all central India fell back into a condition of incessant war and disorder, for the predatory Maratha hordes and bands of armed adventurers overran the country, and were rapidly destroying all the weaker states. Many of the chiefs appealed to the British Government, affirming that the imperial power in India, by whomsoever it had been exercised, had always recognized and acted upon the inherent duty and obligation of protecting the minor states, and of imposing peace and good order throughout the empire. This was the principle upon which Lord Hastings at last interfered, in 1817, to suppress the Pindarees, whose predatory armies roved at large through the midland country, and to preserve the minor chiefships from aggression and gradual dismemberment. The Pindaree hordes were attacked, pursued, and broken up. The great Maratha chiefs were compelled by force of arms to sign treaties acknowledging the supreme prerogative of the British Government for adjusting the reciprocal rights and relations between them and the minor states which they were holding in tributary subjection. The petty chiefships were thus placed under the protection of the British Government; and treaties were made directly with the larger Rajput states, whose independence was thus secured and whose territories were saved from imminent destruction. The same system was extended to the minor states in Gujarat and western India generally, while all the principal states were required to accept the position of subordinate alliance with the British Government, which assumed the paramount powers of supreme authority and control. The rulership in the Punjab and in Sind lay at this period outside the sphere of British dominion. But for all the rest of India it became thenceforward a recognized principle of public policy that every state should make over the control of its foreign relations to the British Government, should submit all disputes to their arbitration, and should defer to British advice regarding internal management. A British resident was appointed to the courts of all the greater princes, while military supremacy was consolidated by locating the subsidiary forces at important capitals, and by placing British officers in command over the auxiliary troops that some states were under obligation to supply.

It is to be observed that under this system, although the British empire increased mightily in territory and in the extension of irresistible influence, yet the original policy of the preservation of native states was never abandoned. The Mahommedan dynasty of Mysore was destroyed in 1799, yet the Mysore state exists, under its ancient Hindu family of rulers, to this day. The Maratha confederacy were the most obstinate of England's enemies, yet none of the five great chiefs who fought against her were completely stripped of their possessions by Lord Wellesley or Lord Hastings, and the descendants of three (Holkar, Sindia, the Gaekwar) still govern considerable states. The barbarous rule of the chief of Coorg, in South India, and his obstinate refusal to amend it, did indeed bring about the absorption of that small state in 1834. But with this exception it may be generally affirmed that the policy of complete annexation and absorption into British territory came in during Lord Dalhousie's Governor-Generalship (1849–56). He declared the doctrine that it was the prerogative, and indeed the duty, of the British Government to assume possession of a subordinate state that should have lapsed to the sovereignty by failure of heirs natural, unless there were some strong reason to the contrary; and he acted on this doctrine by annexing Satára, Nagpore, and Jhansi. The Punjab was taken by conquest after two fierce wars, and the kingdom of Oudh was annexed on the ground of long and incurable misrule. But after the mutiny of 1857 this doctrine was virtually abandoned. The policy now consistently prevailing is expressed by Lord Canning's formal recognition in 1862 of the right of all ruling chiefs, upon failure of heirs natural, to adopt successors according to the customs of their religion, race, or family, so long as they are loyal to the British crown and faithful to their engagements. Yet no subordinate principality can pass to an heir, whether by adoption or ordinary succession, without the assent of the paramount power, a condition that is undoubtedly based on established usage and long tradition.

Present position in the Indian Empire.

We have now traced rapidly the course of events and transactions by which the dominion of the Moghal emperors, which began in the middle of the 16th century, became transformed into the British dominion of India, and was centralized under one great sovereignty during the reign of the Queen-Empress Victoria. Its full development is to be surveyed in the present constitution of the Indian empire, composed partly of the British-Indian provinces and partly of states under British protection and undisputed ascendancy. An official paper issued by the Government of India in 1886 recorded 629 subordinate or feudatory states, with territories aggregating 628,672 square miles and a population of 66 millions. Most of these states—indeed, almost all the larger ones—represent, as has been said, the military chiefships which arose out of the confusion that followed the fall of the Moghal empire, and which the British Government has preserved on a diminished scale instead of absorbing them. Some of them are constituted from the domains that were left to adversaries who submitted after war; others belong to a class which, like the Haidarabad state, were originally allies of Great Britain, and have retained their internal dependence under the limitations imposed by treaties or by the general constitution of the empire. Of the minor chiefships the greater number owe their existence to the protection given them by Great Britain against predatory aggression. They had been tributaries of the larger native states, and the dominion over them was transferred, by conquest or cession, to the British Government, which has now guaranteed their rights and obligations, and allows no other person to interfere with them. Every one of these native states, great and small, has yielded up the management of its external relations to the British Government, and has no sovereign rights internationally; while in all matters that concern the empire at large the states are expected to conform to the decision of the paramount suzerain. In measures taken for the common defence of India they may be required to co-operate, and to permit anything to be done that is necessary for the general safety. On the other hand, the British

Government undertakes to regard their interests in all external affairs as identical with its own, to make no arrangement which would place them at a disadvantage, and to protect them if necessary with the whole force of the empire.

The regulating authority of the British Government is exercised over the states in various modes and degrees. In deciding disputes over succession to the rulership, in questions of adoption, in the control of affairs during minorities, in the limitation of their armaments, and in any matter affecting the peace of the empire, the British Government is supreme arbiter. And since this supreme power is prepared to support the legitimate ruling authority of the chiefs, to assist them in suppressing revolts, and to prevent usurpation, the obligation to interfere for the purpose of checking gross abuses, serious misgovernment, or the excessive squandering of the states' finances, which leads to misrule, necessarily follows. What circumstances constitute a case for such interference, and how far it should be carried, are matters for discretion in each instance. On subjects which concern the general interest, such as commerce, coinage, and railways, the states are expected to defer to the advice of the British Government; over all trunk lines of railway communication, and indeed over every line that does not begin and end within the territory of a single state, the supreme Government retains jurisdiction. The states are all bound to give extradition, on demand, of heinous criminals; and in one department of internal administration, the judicial authority of the chief, there are degrees of limitation. For while in the larger states sentences of death can be passed by the state's tribunals, in others a reference to the British agent is necessary, and in the lesser states the judicial power is graduated according to class or capacity. The residuary superior jurisdiction in these cases is vested in the British Government. Many of these petty chiefs are little more than large proprietors with privileged jurisdiction of a feudal kind, not unlike some of those which existed under the German empire up to the end of the 18th century.

It is necessary to understand clearly the real nature and constitutions of all these native states. In the first place, they in no sense represent nationalities; they are marked off by no differences of language, by no separate community of religion or race; they do not contain homogeneous populations under a national ruler. They are territorial jurisdictions, or imperfect sovereignties, marked out on the general map of India, usually formed by acquisitions, for the most part fortuitous, of each ruling family, and fixed within the limits finally recognized and confirmed by the British Government. With the majority of his subjects the ruler has not necessarily any connexion—religious, tribal, or linguistic. At Haidarabad a Mahommedan prince of foreign descent governs an indigenous population that is mainly Hindu; at Gwalior a Maratha chief from south-west India reigns over millions of northern Indians to whom the Maratha language is foreign—his capital has grown up round the fortress where his ancestor pitched a standing camp. Secondly, it must be explained that there is a great difference in structure between the different groups of these states. Many of them were formed by simple conquest; they are the lands which the founder of the dynasty seized by the power of a mercenary army. But a Rajput state in central and western India denotes the territory over which a particular clan, or division of a clan, claims dominion for its chief and possession for itself by right of ancient settlement and continual habitation, although the existing territorial boundaries were constantly changing under incessant warfare up to the period of British pacification. The chief of the ruling clan is chief of the state, and all the great landholders are usually his kinsmen, while the people who are not Rajputs hold a lower position as merchants and cultivators, or as inferior castes and aboriginal tribes. In the wilder outlying tracts these aboriginal tribes have kept up their local independence in political subordination to the Rajput chief.

Nature and constitution.

For conducting, upon the principles above described, the relations between the Government of India and the native states a system has grown up of establishing political agents, who usually reside within the states' territory. A resident officer of superior rank has charge either of a single important state, or of a group of minor states, having in the latter case other agents of lesser rank under his orders. And since this arrangement is connected historically with the position, geographical or political, of the several chiefships, it may conveniently be followed as a classification in the sketch which will now be given of their origin, their character, and the circumstances that have led up to and determined their existing status within the empire. The superior Agencies correspond directly with the Government of India; but since many of the minor chiefships are by their situation and interests closely intermixed with British provinces, their business is primarily managed by the adjoining local governments, subject to reference, on questions of principle, to the Governor-General in council.

The states of the first magnitude, to each of which a superior Resident is attached, are as follows:—

1. Haidarabad.	4. Gwalior.
2. Mysore.	5. Indore.
3. Travancore.	6. Baroda.
7. Kashmir.	

The first three states in this list are situated in southern India, Travancore being at its extreme promontory. The next three are in the central region; and Kashmir, with its tributaries, lies in the highland country on the farthest northern frontier of the Indian empire.

Haidarabad.

The ruler of this state is entitled the Nizam. His family was founded by Asaf Jáh, a very able military leader, who was appointed in 1714 governor of the great imperial province of the Dekhan, and raised his governorship to an independent principality during the confusion of the next twenty years. His death in 1748 was followed by a war of succession, in which the French and British companies on the south-eastern coast of India took part, and which ended in the rulership of Asaf Jáh's son, with the hereditary title of the Nizam. By that time the French had lost all their political influence in southern India, and the rivalry between the native powers for territory and dominion lay between the Marathas, the Nizam, and the Mahommedan dynasty at Mysore. The English East India Company on the sea-coast, whose position was put in jeopardy by these turbulent neighbours, became entangled in their quarrels; and when hostilities began between Haidarabad and Mysore the Company sent a subsidiary force to co-operate with the Nizam, in consideration of the cession by him of certain districts. But the Nizam soon afterwards made a secret compact with Hyder Ali of Mysore for a joint attack upon the Company. Some sharp fighting ensued, in which the Nizam was so roughly handled by the British that he was glad to make terms.

During the period that followed, the policy of the Haidarabad state varied with the vicissitudes of the incessant contest that went on among the three native powers. With the English Company the Nizam was alternately in

alliance and at enmity; but as his military strength was much inferior to that of the Mysore sultan and of the Marathas, who were also formidable adversaries of the British, the concurrence of their common interests gradually drew the Nizam and the Company into a less unstable alliance. So in the first war (1790) against Tippu, sultan of Mysore, the two Governments acted together in the field, and shared the lands which were wrested from him. But in 1795, when the Marathas invaded the Haidarabad territory, the Nizam's urgent appeal for assistance was rejected by the English Governor-General (Lord Teignmouth), who feared the consequences of joining in hostilities against the Maratha power. The results were, in the first place, that the Marathas routed the Nizam's army and forced him to make peace on very extortionate terms; and, secondly, that the Nizam's deep resentment against the way in which the British had deserted him led him to increase those regiments in his own service that were commanded by French officers, whose influence at his court was proportionately augmented. When, in 1798, Lord Mornington assumed the Governor-Generalship of India, the Nizam's army was largely in the hands of Frenchmen. As war with Tippu of Mysore was imminent, an alliance with the Nizam became again of importance to the English, and the Nizam's own condition forced him to the conclusion that in this alliance lay his only assurance of permanent protection from the Marathas and the powerful hostility of Mysore. He was therefore induced to agree by a treaty to disband the French corps (nearly 14,000 men), to dismiss the officers, and to allow a substantial increase of the troops furnished by the British Government on payment of a subsidy. The Nizam's army co-operated in the war which terminated in the conquest of Mysore, and a considerable share of the conquered territory was handed to Haidarabad. In 1800 was made another treaty, which is not only the foundation of British relations with Haidarabad, but has also served as the model of subsequent relations with other important states. By this treaty the British Government engaged to defend Haidarabad against foreign aggression, while the Nizam placed in British hands the direction of all his foreign affairs, admitted a British force to be stationed at his capital, and ceded territory yielding revenue sufficient to defray the cost of its maintenance. Since that time the only material transaction with the Haidarabad state has been the assignment to the British Government of certain districts yielding a net revenue set apart for the payment of an auxiliary force that the Nizam had undertaken to maintain, the surplus, if any, of revenue after payment of the troops to be credited to the Haidarabad treasury. The districts that are still thus held in trust under British management constitute what is commonly called the province of Berar.

As the Nizam's family is Mahommedan, the nobles and most of the chief officers of the state are of that religion; but a very large majority of the population are Hindu.

Mysore.

The present Maharaja of Mysore has descended from a Hindu dynasty that took its rise in the 15th century. During the confusion that spread over south India in the 18th century the reigning prince was deposed and his kingdom was seized by Haidar Ali, a soldier of fortune, who established a strong military power in that country and pillaged all his neighbours. These incursions, and the active correspondence of the Mysore rulers with the French at a time when France and England were at war, produced a state of intermittent hostility with the British Government, while Mysore was also alternately in alliance or at enmity with the Nizam and the Marathas. In 1780 Haidar Ali invaded the Carnatic with a large army, and ravaged the lands protected or possessed by the East India Company up to the suburbs of Madras, defeating the English troops sent against him. A French squadron appeared off the coast to co-operate with him, but withdrew, and Haidar was at last beaten and driven away at the battle of Porto Novo. His son, Tippu Sahib, carried on the war until peace was made in 1783; but war broke out again in 1791, with the result that a British army under Lord Cornwallis forced him to sign a treaty that ceded half his territory to the British Government. Tippu Sahib nevertheless continued to strengthen his army, to negotiate with France for assistance, and generally to prepare for fresh hostilities, until Lord Mornington formally required him to disarm and relinquish his alliance with France, then again at war with England. On his refusal he was attacked in 1799, was driven into Seringapatam, and besieged there until the place was taken by assault, and Tippu was slain in the fighting. After allotting certain portions of his kingdom to the British Government and its allies in the war, Lord Mornington reconstituted the remainder into a state under the old Hindu reigning family. Then followed a period of oppressive misrule and serious squandering of the revenues, until in 1831 the Government of India placed the state in sequestration, and assumed the direct administration for fifty years. In 1868 it was publicly resolved that the representative of the family, then a minor, should be restored to the rulership, and in 1881 he was formally placed upon the throne. The instrument recording the transfer of the Mysore state to its hereditary ruler laid down certain conditions, territorial, financial, and military, that have been attached to the rendition in accordance with the general principles that govern the reciprocal relations of the native states with the British Government.

Travancore.

The country belonging to this state, which lies along the south-eastern coast-line of India, where it runs down to a point at Cape Comorin, was consolidated out of several petty chiefships into one principality about the middle of the 18th century. It was never conquered by the Moghals, and although the ruler at one time paid tribute to the nearest Mahommedan governor, his successor, finding himself threatened by the sultan of Mysore, obtained aid and protection from the British authorities at Madras. When Tippu of Mysore invaded Travancore in 1789, the British compelled him by force of arms to restore the territory that he had seized; and in 1799 the troops of Travancore joined in the campaign that ended with his death and the extinction of his dynasty in Mysore. In 1805 the state was brought formally within the British protectorate by a treaty in which its ruler acknowledged British suzerainty, and bound himself to the payment of a subsidy toward the maintenance of troops for his territory's defence. With the exception of some internal troubles, which were from time to time suppressed or adjusted by the interposition of the British Government, the state has since had an uneventful history, and is now prosperous and orderly. According to the laws which determine the succession in this state, the descent is in the female line; so that, for example, the rulership would pass on the death of a chief, not to his sons, who can in no case inherit, but to his uterine brothers, or else to his sisters' sons. And if an adoption became necessary for the continuance of his line, a female could be chosen to transmit the succession. The latest adoption of this kind occurred in 1857.

The three states of Gwalior, Indore, and Baroda are alike in their origin. It may be explained that at the

beginning of the 18th century the Marathas had acquired a great dominion in western India under the leadership of the famous Sivaji and his successors, who had rebelled against and driven out the imperial governors in that region. By the middle of the century the house of Sivaji had been supplanted and reduced to merely titular sovereignty by the family of the Peshwas, or prime ministers of the Maratha Government; and the Peshwas in their turn soon found themselves unable to control their own military commanders, who used their troops for seizing territory on their own account, and defied the attempts of the central Maratha power at Poona to enforce subordination. In these three states, therefore, the rulers are the descendants of successful generals who rose to independent power towards the end of the 18th century, who were the leaders of the Maratha confederacy that contended against the British arms in several wars for predominance, and who finally submitted at different times to treaties according the states protection with internal autonomy under British supremacy.

Gwalior.

The Gwalior state was founded by Madhaji Sindia, who had commanded an expedition sent in 1770 by the Maratha Government at Poona into northern India, where he established by conquest a considerable Maratha dominion. His operations brought him into collision with the British, but although he concluded a treaty with them in 1782, the policy of Madhaji and of his able successor, Doulut Rao, naturally continued adverse to the growing power of the British Government. The jealousies and dissensions among the leaders of the Maratha confederation, however, disorganized their resistance to the common enemy. They fought among themselves for territory and for supremacy until the Peshwa, who was the titular head of the confederation, was completely defeated in battle by the Maratha chief Holkar, fled from his capital, and placed himself under British protection by the treaty of Bassein in 1802. This interposition of the British Government was resented by the confederacy, and it brought on the Maratha war of 1803. In the campaign that followed a combined Maratha army, in which Sindia's troops furnished the largest contingent, was defeated by General Arthur Wellesley at Assaye and Argaum, in central India; and Lord Lake routed Sindia's forces in northern India at Agra, Alighur, and Laswaree. Many districts that Sindia had seized in the north and some in the south were ceded to the British Government, and his state's territory was materially reduced.

In 1817, when the Peshwa attempted to raise the Maratha chiefs in combination against the British Government, Sindia was only deterred from joining in the war by a movement of British troops to overawe him, and his connivance with the enemy cost him the compulsory cession of two fortresses. Under Doulut Rao, Sindia's successor, the state fell into confusion and was distracted by mutinies, until the growth of turbulence and misrule on the British border induced Lord Ellenborough to interpose, and a British force advanced upon Gwalior. The Maratha troops were defeated at Maharajpur and Punniar, with the result that the Gwalior government signed a treaty ceding territory with revenue sufficient for the maintenance of a force to be stationed at the capital, and fixing the future strength of the Gwalior army. In 1857 this force joined the general mutiny; the ruling chief abandoned Gwalior until the place was retaken and his authority restored by Sir Hugh Rose (Lord Strathnairn) in 1858; and since that pacification of the country its princes have continued in firm and loyal amity with the British Government.

Indore.

The state of which Indore is the capital had its origin in an assignment of lands made early in the 18th century to Mulhar Rao Holkar, who held a command in the army of the Maratha Peshwa. Before his death in 1765 Mulhar Rao had added to his assignment large territorial possessions acquired by his armed power during the confusion of the period; and by the end of that century the rulership had passed to another leader of the same class, Tukaji Holkar, whose son, Jeswant Rao, took an important part in the contest for predominance in the Maratha confederation. He did not, however, join the combined army of Sindia and the raja of Berar in their war against the British in 1803, but after its termination he provoked hostilities which led to his complete discomfiture. At first he defeated a British force that had marched against him under Colonel Monson; but when he made an inroad into British territory he was completely defeated by Lord Lake, and was compelled to sign a treaty which deprived him of a large portion of his possessions. After his death his favourite mistress, Tulsi Bace, assumed the regency, until in 1817 she was murdered by the military commanders of the Indore troops, who declared for the Peshwa on his rupture with the British Government. After their defeat at Mehidpore in 1818, the state submitted by treaty to the loss of more territory, transferred to the British Government its suzerainty over a number of minor tributary states, and acknowledged the British protectorate. For many years afterwards the administration of the Holkar princes was troubled by intestine quarrels, misrule, and dynastic contentions, necessitating the frequent interposition of British authority; and in 1857 the army, breaking away from the chief's control, besieged the British Residency, and took advantage of the mutiny of the Bengal sepoys to spread turbulent disorder over that part of central India. They were subdued and the country was pacified after some fighting; but the relations of subsequent rulers with the British Government have since been frequently unsatisfactory, although no material change has taken place in their status or territorial settlement up to the present time.

Baroda.

The family of the Gaekwar, the hereditary title of the ruling prince of Baroda, was established about the middle of the 18th century in Gujarat, then a province of the Moghal empire on the western sea-coast of India. The founder of this family had been, like the other Maratha chiefs, a commander in the armies of the Peshwa, and, like the others, his descendant succeeded, after some fighting, in winning his independence and consolidating a separate chiefship. During the latter part of the century the Gaekwars contended with varying fortunes against the attempts of their nominal sovereign, the Peshwa, to regain his supremacy, until in 1780 the state's independence was recognized by a treaty made with the British Government, under which that Government afterwards interposed on several occasions to protect the Gaekwar's territory from dismemberment by his rivals, and to support him against other claimants to the rulership. The mutinies and internal disorders, which are ordinary events in the history of these military chiefships, followed in due course; and the British Government, after lending aid to suppress them, applied the usual remedy of placing at the capital a subsidiary force, to be commanded by British officers and maintained by cession of land yielding revenue equal to its cost. The Gaekwar also had to keep up a body of cavalry for co-operation with the British army when required, and for upholding peace and good order within his own dominion.

It is unnecessary to recount the many instances in which maladministration, financial difficulties, and the caprice of successive princes compelled the British Government to interfere during the 19th century, but it must be mentioned that in 1874 Mulhar Rao Gaekwar was deposed, after a formal trial instituted by the Viceroy's order, for proved unfitness and incapacity. The widow of his predecessor was allowed to adopt a child, one of the family, who after the expiry of his minority was placed upon the throne, and has since proved himself a loyal and very capable ruler.

Kashmir.

The territory ruled by the Maharaja of Kashmir, with its tributary chiefships, comprises a wide highland region of 80,000 square miles, situated between the northern frontier of the Punjab and the Mustagh and Karakoram ranges of high mountains which mark the south-west frontier of Chinese Tibet. The early history of this country is obscure, although several invasions by the first Mahommedan conquerors of India are recorded, until the southern portion, Kashmir proper and Jamu, was finally annexed to his Moghal empire by Akbar in 1587. But when Nadir Shah, the Persian, overran northern India and had sacked Delhi in 1735, he afterwards occupied Kashmir, which was incorporated with the kingdom of Kabul, and remained under that sovereignty until the Mahommedan governor of Kashmir revolted and made himself independent in 1809. Ten years later it fell beneath the rising power of the Sikhs, became a province of Ranjit Singh's kingdom in the Punjab, and on the conclusion of the campaign in 1846, in which the Sikh army was defeated after some fierce battles by the British, Kashmir was surrendered to the British Government and transferred as an independent rulership to Raja Golab Singh, the Sikh governor, who had assisted the British forces during the war.

Rajputana.

In the official nomenclature of India Rajputana denotes a group of nineteen states, with varying area and importance, having each its own autonomy and separate chief, whose aggregate territories extend across India from the borders of the North-West Provinces and the Punjab on the east and north to Sind and the Bombay Presidency on the west. To the south Rajputana marches with the states of central India. Sixteen of these states are ruled by chiefs of different Rajput clans, two of them by chiefs of the Ját tribe, and one by a Mahommedan prince. If the three last-mentioned states are for the present set aside, Rajputana may be described as the region within which the Rajput clans have maintained their independence under their hereditary chiefs ever since the Mahommedan irruptions drove them out of northern India to seek fresh settlements in the wilder and less accessible country where they are now found. Here they maintained constant resistance against the Mahommedan powers, until in the 16th century they submitted to the suzerainty of the Emperor Akbar, and began to furnish contingents to the Moghal armies in the incessant wars of the empire. When that empire collapsed the Rajput states were very nearly involved in its ruin, for during the political anarchy of the 18th century they were invaded, pillaged, and almost brought under subjection by the Marathas and other predatory leaders. And although at the beginning of the 19th century the Maratha confederacy was broken up by the British forces, the Rajput states were incessantly harried and plundered by Pindarees and others, until, in 1818, the English Governor-General, Lord Hastings, interfered to save and protect them. Then ensued a great rectification of boundaries and restoration of territory that had been violently seized. The Rajput states made treaties acknowledging the British supremacy, and the whole country has thenceforward enjoyed security, disturbed only by a short period of confusion during the sepoy mutiny of 1857, and by occasional disorders that have arisen out of misrule or disputed successions in particular states.

The geographical position, within Rajputana, of the nineteen states may be roughly given as follows:—In the west and north are Marwar or Jodhpur, Bikanir, Jesulmer, ruled separately by chiefs belonging to the same clan. In the north-east is Alwar and a tract called the Shaikhawati, subject indirectly to Jaipur. Jaipur, Bhartpur and Dholpur (the two Ját states), Karauli, Bundi, Kotah, and Jhalawar may be grouped together as the eastern and south-eastern states. The southern states are Partabgarh, Banswara, Dungarpur, and Meywar or Oodipur, with its subordinate chiefship of Shahpura. Sirohi lies in the south-west corner, Kishangarh near the centre, while the Mahommedan state of Tonk consists of six isolated patches of territory. The Rajput states, ruled by the hereditary chiefs of the clans, represent by far the oldest principalities in India, tracing their origin to a period long anterior to the Moghal empire, whereas we have seen that almost all other states in India arose in the confusion that followed the empire's dissolution. The states of Bhartpur and Dholpur were founded towards the end of the 18th century by families of the Ját tribe, and Tonk is formed out of the lands confirmed in the possession of a famous freebooting leader, Amir Khan, by the British Government in 1817.

Central India.

Under this official heading are grouped a number of states lying to the south and east of Rajputana. They include seventeen principal states, of which the largest are Gwalior and Indore, already noticed separately, and a number of petty chiefships that had been made tributaries to the great Maratha states, but which are now under the immediate protection of the British Government. Many of the minor chiefships belong to Rajput families; others were acquired by Maratha leaders at the time when this part of India had fallen almost entirely under the Maratha domination; and Bhopal was founded early in the 18th century by an Afghan commander in the service of the Moghal emperor. The petty chiefships of Dewas and Dhar are ruled by the descendants of an ancient Maratha family which acquired lands in central India during the 18th century.

At the close, in 1818, of the Pindaree war the whole country that is now under the central Indian agency was in great confusion and disorder, having suffered heavily from the extortions of the Maratha armies and from the predatory bands. It had been the policy of the great Maratha chiefs, Holkar and Sindia, to trample down into complete subjection all the petty Rajput princes whose lands they seized and from whom they levied heavy contributions of money. Many of these minor chiefs had been expelled from their possessions, had taken refuge in the hills and forests, and retaliated upon the Maratha usurpers by wasting the lands which they had lost until the Marathas compounded for peace by payment of blackmail. In this state of affairs all parties agreed to the interposition of the British Government for the restoration of order, and under Lord Hastings the work of pacification was effected. The policy pursued was to declare the permanency of the rights existing at the time of the British interposition, conditionally upon the maintenance of order; to adjust and guarantee the relations of subordinate and tributary chiefs with their

superiors, so as to prevent all further disputes or encroachments; and to settle the claims of the ousted landholders who had resorted to pillage or blackmail, by fixing grants of land to be made to them, or settling the money allowances to be paid to them. The general result was to place all the privileges, rights, and possessions of these inferior chiefs under the guarantee or protection of the British Government, to whom all disputes between the superior and inferior states must be referred, and whose decision is final upon all questions of succession to hereditary rights or rulership.

Other States.

There is also a group of minor states lying along the south-west border of the British North-Western Provinces, in political relation with the Central Indian agency, whose country has the general name of Bundelkhand. In number they are thirty-one, the largest being Rewa; and most of them resemble in origin and formation the states in Rajputana, being ruled by chiefs of dominant Rajput clans. Their history is similar to that of the Central Indian chiefships: they were invaded and partly subdued in the course of the 18th century by the Maratha powers; they suffered much from the confusion of that period, until at the beginning of the 19th century some of them placed themselves under the protection of the British Government; and when, in 1817, the Peshwa ceded all his sovereign rights over this country to the British, a general settlement ensued. Some portions of the territory accrued, by cession or lapse, to the British Government; and all the remaining chiefships were secured in their rights and possession by treaties or grants, or by taking acknowledgments of fealty, on the usual conditions of allegiance and orderly rule.

The very numerous minor states not belonging to the groups that have already been described are all attached, for supervision and immediate control, to the local governments of the British provinces to which they are adjacent, or within whose territories they are enclosed, important political questions being referred to the Government of India. They may be thus classified:—

States in relation with the Punjab, including the petty Himalayan chiefships.

States in relation with the North-West Provinces and Bengal.

States within or attached to the Bombay Province.

States within or adjacent to the Central Provinces.

States within or adjacent to the Madras Province.

The petty chiefships and tribal tracts on the borderland between Burma and China or Siam, and on the north-eastern frontier of Assam, can hardly be reckoned geographically among the native states of India, although they are in political subordination to the nearest local governments, or, as in the case of Manipur, to the Government of India. There are, moreover, some important states situated within the great mountain ranges that separate India from the rest of Asia, which are in treaty relations with the British Government, and over which that Government maintains a protectorate, in the sense of allowing no interference with them by any foreign Power. In this class may be placed Bhotan and Sikkim on the north-east frontier, with Nepal; and Gilgit, Hunza, and Chitral on the extreme north-west frontier of the Indian empire. Between the north-west border of the Punjab province and the kingdom of Afghanistan are the highlands inhabited by various unruly tribes, whom the Indian Government is gradually bringing under some control. And beyond the western frontier of India, extending to the borders of Persia, lies Baluchistan, a wide, sparsely populated region, occupied by tribes under the nominal headship of the khan of Kelat. It may be classed as a protectorate under the superintendence of a British Resident at Quetta, a military station in the British district that has been established at the north-eastern corner of Baluchistan.

Further details concerning the native states will be found under the separate headings. (A. C. L.)

India, French.—This name denotes the French establishments in India—on the Coromandel coast, Pondicherry and Karikal; on the Orissa coast, Yanaon; on the Malabar coast, Mahé; and in Bengal, Chandarnagar. In addition there are a few "lodges" divided among these five districts, but they are merely nominal remnants of French dominion. The total area extends to about 200 square miles, of which 120 square miles belong to the territory of Pondicherry. In 1897 the total population amounted to 283,053, that of Pondicherry being 172,941 (city only, 48,473); of Karikal, 70,526; of Chandarnagar, 24,281; of Mahé, 9978; of Yanaon, 5327. In 1901 the total was only 273,185. By decree of 25th January 1879 French India was provided with an elective general council and elective local councils. The results of this measure have not been very satisfactory, and the qualifications for and the classes of the franchise have been variously modified. The governor resides at Pondicherry, and is assisted by a privy council. There are two tribunals of first instance (at Pondicherry and Karikal), one court of appeal (at Pondicherry), and five justices of the peace. The local budget for 1901 balanced at £78,135. In the colonial budget of France for 1900 the possessions figured for £18,200. The debt (annuity) amounts to £4000. The agricultural produce consists of rice, earth-nuts, tobacco, the betel nut, and vegetables. Earth-nut cultivation is passing through a serious crisis, which has considerably affected the trade of Pondicherry. There are 35,000 head of cattle. Pondicherry manufactures and exports "quinées" and muslins; Karikal, linen cloth; Chandarnagar, jute; Mahé, spirits.

The following table shows the value of the imports and exports in 1898:—

District.	Imports.	Exports.
Pondicherry	£83,000	£231,000
Karikal	36,000	82,800
Chandarnagar	...	...
Mahé	2,400	1,900
Yanaon	3,800	500
Total	£125,200	£316,200

Of the total imports France sent to the value of £82,500; of the total exports she received to the value of £19,600. In 1899 the imports reached a total value of £192,560 (£59,520 from France), and the exports a value of £371,320 (£119,320 to France). The trade with France has declined more rapidly than the general trade, though that has fallen from a total (imports and exports) of £1,020,000 in 1888. British India and Great Britain have a predominating share in both imports and exports. At Pondicherry and Karikal, in 1898, 397 vessels of 543,760 tons entered, and 397 of 543,710 tons cleared.

See HAURIGOT. *French India.* Paris, 1887.—HENRIQUE. *Les Colonies Françaises.* Paris, 1889.—LEE. *French Colonies.* Foreign Office Report, 1900.—*L'Année Coloniale.* Paris, 1900. (P. L.)

Indiana, one of the central states of the American Union, was admitted into the Union in 1816. Then it was the most westerly state on the frontier. The centre of population of the United States now rests within her borders. The soil is fertile, the climate equable, the average temperature being 52° F., and the rainfall $39\frac{26}{100}$ inches per annum.

Population.—The population has increased steadily

from the first, and, as shown by the national census, nearly constantly at the rate of 300,000 in each decade except that ending with 1890. In 1890 the population was 2,192,404, of whom 2,046,199 were native and 146,205 foreign-born. In 1900 it was 2,516,462, showing an increase of 324,058, or 14·8 per cent., as compared with 214,103, or 10·8 per cent., in the preceding ten years. Of the total population in 1900, 1,285,404 (51·1 per cent.) were males, and 1,231,058 (48·9 per cent.) females; 2,374,341 native-born, and 142,121 (5·6 per cent.) foreign-born; 2,458,502 were white, and 57,960 (2·3 per cent.) coloured, of whom 57,505 were negroes, 207 Chinese, 5 Japanese, and 243 Indians. The total land surface is approximately 35,910 square miles, so that the average number of persons per square mile was 70·1 in 1900, as compared with 61·1 in 1890. There were in 1900 42 incorporated places with more than 5000 inhabitants; of these 23 had between 5000 and 10,000 inhabitants, 14 had from 10,000 to 25,000, and 5 had more than 25,000. These 5 were Indianapolis with 169,164, Evansville with 59,007, Fort Wayne with 45,115, Terre Haute with 36,673, and South Bend with 35,999. In 1890 the urban population (persons in cities of 8000 inhabitants or more) was 400,566, or 18·3 per cent. of the total population of the state; in 1900 it was 607,834, or 24·2 per cent. of the total population.

Agriculture.—Agriculture was the first, and remains the chief industry. All kinds of cereals, fruits, and domestic animals, common to the temperate zone, are raised throughout the state. In 1900 there were grown 169,926,921 bushels of corn, and in 1899 31,357,099 bushels of wheat. In 1899 farm products yielded an aggregate value of $167,967,870.

Coal, Gas, and Oil.—Since 1880 great progress has been made in mechanical and mining industries, owing largely to the development of the coal-fields and the discovery of natural gas and petroleum. The coal-fields lie in the south-western part, and have an area of 7560 square miles. The coal is practically inexhaustible, excellent in quality, and finds a ready market in the state, and also in Chicago, St Louis, and other cities. It is a favourite fuel with railway companies. The output was 4,228,086 tons in 1897, 5,177,044 tons in 1898, and 6,283,063 in 1900. Natural gas was discovered in 1884. It was soon ascertained that the field was the largest known in the United States. It covers an area 100 miles long and 70 miles wide, between Indianapolis and Fort Wayne. The gas is found in a porous (Trenton) limestone, at an average depth of 1000 feet. Since 1887 it has been used almost exclusively for fuel and light over the entire field. At first the natural pressure (325 pounds to the square inch) was sufficient to carry it for many miles, and it was supplied through pipes to the towns and cities within 40 or 50 miles of the rim of the reservoir, and used for fuel. Pipe lines also extend to Chicago, Dayton, and other cities, the natural force being supplemented by artificial power. The enormous draft on the reservoir is reducing the pressure and narrowing the area. The state has passed necessary laws to prevent waste. Soon after the discovery of gas, oil was found just underneath it. In popular parlance, "as gas gives out oil comes in." A dead gas well is sometimes turned into a live oil well. On 1st January 1900 there were in the state 5480 wells, producing oil at the rate of 4,912,675 barrels per year. Coal, gas, oil, and other resources, including great beds of Oolite limestone and excellent clays, have since 1880 made Indiana a great manufacturing state. The gas field has become a hive of industry. Glass of all kinds, tin-plate, iron and steel products, wire, nails, tiles, bricks, and many other articles are manufactured.

Manufactures.—The condition of manufacturing industries in 1890 and 1900 is shown in the following general table:—

	1890.	1900.	Per Cent. of Increase.
Number of establishments . . .	12,354	18,015	45·8
Capital . . .	$131,605,366	$234,481,528	78·2
Wage-earners (exclusive of salaried officials, clerks, &c.) .	110,590	155,956	41
Total wages . .	$42,577,258	$66,847,317	57
Miscellaneous expenses	$16,500,903	$33,052,160	100·3
Cost of materials used	$130,119,106	$214,961,610	65·2
Value of products . .	$226,825,082	$378,120,140	66·7

The following table shows the statistics of the leading industries:—

Industry.	Number of Establishments.	Wage-Earners.	Value of Products.
Flouring and grist mill products . . .	897	2,124	$30,150,766
Foundry and machine-shop products . .	337	10,339	17,228,096
Glass	110	13,015	14,757,883
Iron and steel . .	27	7,579	19,338,481
Liquors, distilled and malt	66	1,281	22,738,105
Lumber and timber products	1849	9,503	20,613,724
Slaughtering and meat packing . . .	36	3,597	43,862,273

Railways.—Railway facilities have developed hand in hand with the manufactures. The mileage rose from 4963 in 1880 to 9072 in 1900, and the business has grown in a greater ratio. Nineteen through lines cross the state from east to west, and eight lines from north to south. Over these through lines passes almost the whole of the trans-continental traffic. The gross earnings in the state on domestic and through traffic were reported in 1898 as follows: Local freight traffic, $49,903,808; through freight traffic, $39,127,558; local passenger traffic, $20,827,316; through passenger traffic, $6,235,542.

Valuation, Banks, &c.—The assessed valuation of all property in the state in 1880 was $767,387,172. The appraised value for 1900 was as follows:—

Value of lands	$452,647,064
Improvement on lands	84,058,993
Value of lots	159,572,824
Improvement on lots	162,450,544
Personal property	318,942,386
Railway property	153,938,059
Telegraph, Telephone, Express and Sleeping Car Companies	6,136,828
	$1,337,746,698

The state debt on 1st July 1901 was only $4,204,615. In 1901 there were 123 national banks, with resources amounting to $97,142,000; 104 state banks, with resources amounting to $25,644,273; 29 trust companies, with resources amounting to $12,335,207; 5 savings banks, with resources amounting to $7,237,684; 408 building and loan associations, with resources amounting to $31,435,587. The business done through the Indianapolis clearing-house in 1898 was $272,285,316; in 1899 it was $304,242,272.

Education and Charities.—Education is general and compulsory. In 1901 there were in the state 757,616 persons of school age (between six and twenty-one). All children between seven and fourteen are required to attend public, private, or parochial schools for a period each year not less than the length of the term of the public school in the district in which the child lives, which in 1901 was at least six months. The average length of the annual term throughout the state was 152 school days. Attendance is enforced by truant officers. Out of 720,206 males of voting age, 40,016 were illiterate (unable to write), of whom 7083 were foreign-born and 5042 were negroes. The state maintains graded and high schools, a university at Bloomington, a normal school at Terre Haute, and an agricultural and mechanical school (Perdue) at La Fayette. In 1898 there were twenty-seven higher institutions of learning in the state, with 4422 students and 537 instructors. The state also maintains a school for the orphans of soldiers and sailors. It also maintains four hospitals for the insane, with 3520 inmates; one school for the blind, with 135 inmates; one school for the deaf and dumb, with 336 inmates; one boys' reform school, with 562 inmates; one girls' reform school, with 56 inmates; one prison for confirmed criminals, with 769 inmates; one prison for reforming criminals, with 918 inmates; one women's prison, with 253 inmates. Over all these institutions a state board of charities exercises a general supervision, and also over the gaols and poorhouses throughout the state.

Religion.—In 1900 the number of communicants or members of the principal religious denominations in the state was as follows: Roman Catholic, 145,269; Methodist, 174,862; Baptist, 52,992; Presbyterian, 43,433; Lutheran, 59,697; Disciples of Christ, 92,788; Protestant Episcopal, 5603; Congregational, 3732. The total membership of all denominations was 725,409.

Local Government.—In 1899 the state adopted a new system of local administration, which is still in its experimental stage. In each township the voters elect a board of advisers, in whom is

vested the legislative power of settling the township expenditures for the ensuing year and levying taxes to meet the authorized outlay. In each county a board of seven councillors is elected, with similar powers and duties. These bodies are in fact local legislatures. They sit in public on certain fixed days, and pass the appropriations and levy the taxes for their several localities. Other local officers are charged with executing these laws, but they are prohibited from creating any debts except as authorized by the proper local boards. It is thought that this entire separation of legislative and executive duties will work a reform in the administration of local affairs and conduce to the public welfare.

Since 1860 the population has doubled, and owing to deaths, immigration, emigration, and natural growth, has almost entirely changed; yet the political division of the voters has been so nearly equal that, during the period 1860–1900, each party won the election ten times, and owing to the presence of a small third party neither has generally polled quite 50 per cent. of all the votes cast. In the Presidential election of 1900 the total of votes cast was 664,094, of which 336,063 were Republican and 309,584 Democrat. Constant rivalry and change have resulted in an honest administration of state affairs, and continued interest has not only trained many men to the duties of government and developed them into wider fields of statesmanship, but it has aroused others to activity in literature and art. (A. C. H.)

Indianapolis, the capital and chief city of the state of Indiana, U.S.A., situated in the centre of the state, in 39° 47′ N. lat., 86° 6′ W. long. In 1900 it embraced an area of 17,792 acres. Its population in 1890 was 105,436; in 1900, 169,164, with a death-rate of 16·7. Of the total population in 1900, 17,122 were foreign-born and 15,931 negroes. There were 48,597 persons of school age (5 to 20 years inclusive). Out of 52,544 males of voting age, 2526 were illiterate (unable to write). The streets are broad, well paved, shaded, and are often lined with lawns on either side. The state house and the court house stand in the centre of large squares, and the new post-office building is surrounded by a park. These, with its broad and shady streets and its many parks, aggregating in all over 1200 acres, make it one of the beautiful cities of the United States. The monument erected by the state in the centre of the city at a cost of over half a million dollars, to the memory of her soldiers and sailors of the Civil War, was designed by Bruno Schmidt of Berlin and executed in part by Macmonnies, and is considered to possess fine artistic qualities. There is an art school, and the University of Indianapolis, founded in 1896, has more than a thousand students. In 1900 there were 1910 manufacturing establishments with a capital of $36,828,114, an average number of 25,511 wage-earners (exclusive of salaried officials, clerks, &c.), and products valued at $68,607,579. The most important industry was that of slaughtering and meat packing, with four establishments, 1920 wage-earners, and products valued at $18,382,679. Other important industries with the value of their products were: carriages and waggons, $2,264,928; flouring and grist mill products, $3,820,373; foundry and machine-shop products, $5,733,469.

As a railway centre Indianapolis is one of the leading cities of the Union, owing largely to its geographical position at a point where the roads connecting north and south, east and west, naturally converge. It is estimated that 25,000 passengers daily pass through the Union Station near the heart of the city. The freight traffic is handled on a loop line (the Belt Railway) through the outskirts, over which a million cars pass annually. Indianapolis is the great live-stock market for the Ohio valley, and the third largest in the United States. The railway traffic, together with the introduction of natural gas as a cheap fuel, has given a great impetus to industrial enterprise. In addition to the steam railways, electric street railways diverge from the centre of the city and run to many surrounding towns. The assessed value of real and personal property in 1900, on a basis of about two-thirds of the full value, was $126,675,040, and the total tax rate for all purposes was $19·20 per thousand dollars. The power to create municipal debts is limited by the state constitution to 2 per cent. of the approved value. The debt in 1900 was $2,152,000. The capital invested in manufactures in 1890 was over fifteen million dollars, and the value of the product $36,426,974. (A. C. H.)

Indian Ocean, The, bounded on the N. by India and Persia; on the W. by Arabia and Africa, and the meridian passing southwards from Cape Agulhas; and on the E. by Farther India, the Sunda Islands, West and South Australia, and the meridian passing through South Cape in Tasmania. As in the case of the Atlantic and Pacific Oceans, the southern boundary is taken at either 40° S., the line of separation from the great Southern Ocean, or, if the belt of this ocean between the two meridians named be included, at the Antarctic Circle. It attains its greatest breadth, more than 6000 miles, between the south points of Africa and Australia, and becomes steadily narrower towards the north, until it is divided by the Indian peninsula into two arms, the Arabian Sea on the west and the Bay of Bengal on the east. Both branches meet the coast of Asia almost exactly on the Tropic of Cancer, but the Arabian Sea communicates with the Red Sea and the Persian Gulf by the Straits of Bab-el-Mandeb and Ormuz respectively. Both of these, again, extend in a north-westerly direction to 30° N. Murray gives the total area, reckoning to 40° S. and including the Red Sea and Persian Gulf, as 17,320,550 English square miles, equivalent to 13,042,000 geographical square miles. Karstens gives the area as 48,182,413 square kilometres, or 14,001,000 geographical square miles; of these 10,842,000 square kilometres, or 3,150,000 geographical square miles, about 22 per cent. of the whole, lie north of the equator. For the area from 40° S. to the Antarctic Circle, Murray gives 9,372,600 English square miles, equivalent to 7,057,568 geographical square miles, and Karstens 24,718,000 square kilometres, equivalent to 7,182,474 geographical square miles. The Indian Ocean receives few large rivers, the chief being the Zambezi, the Shat-el-Arab, the Indus, the Ganges, the Brahmaputra, and the Irawadi. Murray estimates the total land area draining to the Indian Ocean at 5,050,000 geographical square miles, almost the same as that draining to the Pacific. The annual rainfall draining from this area is estimated at 4380 cubic miles.

Relief.—Large portions of the bed still remain unexplored, but a fair knowledge of its general form has been gained from the soundings of H.M.S. *Challenger*, the German *Gazelle* Expedition, and various cable ships, and in 1898 information was greatly added to by the German *Valdivia* Expedition. A ridge, less than 2000 fathoms from the surface, extends south-eastwards from the Cape (see ATLANTIC OCEAN). This ridge, on which the Crozet Islands and Kerguelen are situated, is directly connected with the submarine plateau of the Antarctic. From it the depth increases north-eastwards, and the greatest depression is found in the angle between Australia and the Sunda Islands, where "Wharton deep," below the 3000-fathom line, covers an area of nearly 50,000 square miles. Immediately to the north of Wharton deep is the smaller "Maclear deep," and the long narrow "Jeffreys deep" off the south of Australia completes the list of depressions below 3000 fathoms in the Indian Ocean. The 2000-fathom line approaches close to the coast except (1) in the Bay of Bengal, which it does not enter; (2) to the south-west of India along a ridge on which are the Laccadive and Maldive Islands; and (3) in the Mozambique Channel, and on a bank north and east of Madagascar, on which are the Seychelles, Mascarene Islands, and other groups.

Islands.—Like the Pacific, the Indian Ocean contains more islands in the western than in the eastern half. Towards the centre, the Maldive, Chagos, and Cocos groups are of characteristic coral formation, and coral reefs occur on most parts of the tropical coasts. There are many volcanic islands, as Mauritius, the Crozet Islands, and St. Paul's. The chief continental islands are Madagascar, Sokotra, and Ceylon. Kerguelen, a desolate and uninhabited island near the centre of the Indian Ocean at its southern border, is noteworthy as providing a base station for Antarctic exploration.

Volume and Mean Depth.—The greatest depth hitherto recorded is 3232 fathoms, by the *Valdivia*, in 18° 18′ S. and 96° 20′ E. Karstens gives the total volume of the ocean down to 40° S. as 187,396,627 cubic kilometres, or 29,352,683 (geographical) cubic miles, whence he obtains a mean depth of 2216 fathoms. Calculating for the area down to 66½° S., he finds the volume to be 266,354,254 cubic kilometres, or 41,720,132 cubic miles, giving a

mean depth of 1997 fathoms. Murray's value for the total volume (to 40° S.) is 44,446,700 (English) cubic miles, giving a mean depth of 2286 fathoms. For the areas and depths at different levels Murray gives the following:—

Depth (Fathoms).	Area (Square Miles).	Volume (Cubic Miles).
0–100	979,500	1,910,300
100–500	809,100	7,243,800
500–1000	551,700	8,720,100
1000–2000	1,596,950	16,416,100
2000–3000	13,344,600	10,153,550
3000–4000	38,700	2,850
	17,320,550	44,446,700

Deposits.—The bottom of the Bay of Bengal, of the northern part of the Arabian Sea, of the Red Sea and the Persian Gulf, and of the narrow coastal strips on the east and west sides of the ocean, are chiefly covered by blue and green muds. Off the African coasts there are large deposits of Glauconitic sands and muds at depths down to 1000 fathoms, and on banks where coral formation occurs there are large deposits of coral muds and sands. In the deeper parts the bed of the ocean is covered on the west and south by Globigerina ooze, except for an elongated patch of red clay extending most of the distance from Sokotra to the Maldives. The red clay covers a nearly square area in the eastern part of the basin bounded on two sides by the Sunda Islands and the west coast of Australia, as well as two strips extending east and west from the southern margin of the square along the south of Australia and nearly to Madagascar. In the northern portion of the square, north and east of Wharton deep, the red clay is replaced over a large tract by Radiolarian ooze.

Temperature.—The mean temperature of the surface water is over 80° F. in all parts north of 13° S., except in the north-west of the Arabian Sea, where it is somewhat lower. South of 13° S. temperature falls uniformly and quickly to the Southern Ocean. Between the depths of 100 and 1000 fathoms temperature is high in the north-west, and in the south centre and south-west, and low in the north-east, the type of distribution remaining substantially the same. At 1500 fathoms temperature has become very uniform, ranging between 35° and 37° F., but still exhibiting the same type of distribution, though in a very degenerate form.

Salinity.—The saltest surface water is found in (*a*) the Arabian Sea and (*b*) along a belt extending from West Australia to South Africa, the highest salinity in this belt occurring at the Australian end. South of the belt salinity falls quickly as latitude increases, while to the north of it, in the monsoon region, the surface water is very fresh off the African coast and to the north-east. Little is known with certainty about the distribution of salinity in the depths, the number of trustworthy observations available being still very small. Probably the northern and north-eastern region, within the monsoon area, contains relatively fresh water down to very considerable depths.

Circulation.—North of the equator the surface circulation is under the control of the monsoons, and changes with them, the currents consisting chiefly of north-east and south-west drifts in the open sea, and induced streams following the coasts. During the northern summer the south-west monsoon, which is sufficiently strong to bring navigation practically to a standstill except for powerful steamers, sets up a strong north-easterly drift in the Arabian Sea, and the water removed from the east African coast is replaced by the upwelling of cold water from below; this is one of the best illustrations of this action extant. Along the line of the equator the *Indian counter-current* flows eastwards all the year round, acting as compensation to the great *Equatorial current* flowing westwards between the parallels of 7° and 20° S. The equatorial current, on meeting the northern extremity of Madagascar, sends a branch southwards along the east coast of that island, sometimes called the *Mascarene current.* When the main equatorial current reaches the African coast a minor stream is sent northwards to the source of the Indian counter-current, but the discharge is chiefly by the *Mozambique current*, which south of Cape Corrientes becomes the *Agulhas current*, one of the most powerful stream currents of the globe. On the west coast of Madagascar and on the banks off the African coast south of 30° S., reaction currents or "back-drifts" move in the opposite direction along the flanks of the Agulhas current; these back-drifts are of great importance to navigation. On clearing the land south of the Cape the waters of the Agulhas current meet those of the *west wind drift* of the Southern Ocean, and mingle with them in such a manner as to produce, by interdigitation, alternate strips of warm and cold water, which are met with at great distances south-west and south of the Cape. Between South Africa and Australia the waters form a part of the great west wind drift. The waters of this drift are, in general, of very low temperature, but it is remarkable that the interdigitation just mentioned continues far to the eastward, at least as far as Kerguelen. This fact is probably due partly to the actual intrusion of warm water from the Mascarene current east of Madagascar, and partly to the circumstance that the different temperatures of the waters are so compensated by their differences of salinity that they have almost precisely the same specific gravity *in situ*. The west wind drift sends a stream northwards along the west coast of Australia, the *West Australia current*, the homologue of the Benguela current in the South Atlantic. The principal feature in the circulation in the depths of the Indian Ocean is a slow movement of Antarctic water northwards along the bottom to take the place of that removed from the surface by evaporation, and by currents in the lower latitudes. Little is known beyond the bare fact that such movement does take place.

(H. N. D.)

Indians, North American.—The last quarter of the 19th century was marked by a few significant uprisings among the Indian tribes of the United States. The year 1875 closed with the Indians generally peaceable, although trouble had been anticipated with mixed bands of Sioux, under Sitting Bull, who had refused to recognize Federal authority, and who for some years had been leading a roving life, plundering and murdering settlers and extending their hostility to friendly tribes. This force, numbering 3000, was augmented from time to time; and early in 1876, owing primarily to infraction of treaty stipulations by the white invasion due to the discovery of gold in the Black Hills, a large number of starving Sioux fled from their agencies and joined the hostiles. As the Indians refused to return to their reservations when so ordered, the matter was placed in the hands of the War Department, 1st February 1876.

Sioux rising of 1876.

Under the leadership of Sitting Bull, Crazy Horse, and others, the uprising assumed a more general nature by the enlistment of the northern Cheyennes in the Sioux cause. The first blow was struck by Crook, who surprised the camp of Crazy Horse, 16th March, and destroyed 110 lodges and other property. Later a force of about 2700 men (besides the Crow scouts), in three columns, under Terry, Gibbon, and Crook, was made ready; and on 17th June the last mentioned, with 1000 men, met the enemy near Rosebud river, and after fighting for six hours the Indians retired. On 22nd June Custer, with 7th cavalry, was sent up the Rosebud, and continued up that stream until the evening of the 24th, the next morning passing over the divide to the Little Big Horn, where the Sioux were discovered. Custer divided his regiment into four commands, his own comprising 262 men. Continuing a few miles down stream, he soon came upon what was supposed to be a single Sioux village, and began to attack its lower end; the Indians, however, proved to number from 8000 to 10,000, including 2500 to 3000 warriors. Custer's little force was soon completely surrounded, and the entire command, save a single Crow scout, was slaughtered. The Indians now separated into two bands, under Sitting Bull and Crazy Horse, who were soon reinforced by other reservation Indians. Fresh troops were hurried forward. On 29th September a band under American Horse was defeated and their leader killed. In October Sitting Bull was pursued by Colonel Miles for 40 miles, and by the close of the month about 5000 Indians surrendered. The campaign continued throughout the winter and early spring under Crook and Miles, and several fights occurred, in which the Indians suffered severely. In March 1877 300 surrendered, and these were followed on 22nd April by 2000 under Crazy Horse. Sitting Bull, however, eluded capture, and crossing the Canadian border was soon largely reinforced. This warrior held out defiantly until 1880, when he returned to Dakota with his 2856 followers and surrendered. One of the immediate effects of the beginning of this revolt was the appointment of a commission which negotiated for the surrender of the Black Hills country. The treaty was approved by Congress on 28th February 1877.

Trouble in Idaho.

Before the conclusion of difficulties with the Sioux trouble was experienced with the Nez Percés of northern Idaho, the course of which was similar to that of most of the Indian hostilities—the discovery of gold, the influx of miners and settlers, the establishment of towns on Indian lands, the confiscation of Indian property. To regulate the difficulties a series of treaty commissions was appointed, which succeeded in effecting a reduction of the Indian tribal lands, although the action was bitterly opposed by a non-treaty element of the tribe. Such, in brief, were the transactions up to 1875; then a member of the band of chief Joseph, the leader of the non-treaty Nez Percés, was killed by whites, and the Indians are said to have made depredations on the crops of the latter; while a

native religious sect, known as Dreamers, under the leadership of Smohalla, tended to widen the breach. Matters grew so serious that, in October 1876, another commission was appointed, and in December it recommended that the medicine-men be ordered to their reservation, that Wallowa valley be occupied by the military, and that Joseph and his band be placed on Lapwai reserve. These recommendations were adopted, and a force was despatched under General O. O. Howard. In May 1877 he held three councils with the discordant Indians, and even induced them to visit Lapwai reserve to select their lands; but when the time came for leaving their ancestral home, although Joseph used his influence to avert the clash, open hostilities began on 14th June by the massacre of twenty-one white men and women in revenge for the recent murder of one of the Nez Percés by white robbers. From this time the fighting between Joseph's hundred warriors and the troops was brave, though severe; but surrounded by an overwhelming and well-equipped force, hindered in their movements by 350 helpless women and children, and discouraged by the loss of some of their leaders, the struggle ended on 5th October, after a retreat of over a thousand miles, probably unequalled in Indian warfare, by the surrender of almost the entire force to Colonel Miles on condition that they were placed on Lapwai reserve. Regardless of this agreement, the surrendered Nez Percés were sent to Quapaw Agency, Indian Territory, whence, after seven years of delay, and the loss by death of nearly two-thirds of the band, they were returned to the north-west.

These experiences seemed to be of little avail in causing the Government to carry out its treaty obligations; consequently there were outbreaks by the Indians, owing mainly to the loss of their hunting lands, the diminution of the bison herds, and the failure of Congress to render timely relief. It was principally these causes which led to the Bannock outbreak of 1877, their trouble, like that of the Nez Percés, being of long standing. The climax was almost reached early in the year named, when, during the exciting times of the Nez Percés war, the Bannocks were forced to remain on their inhospitable reservation, to face the continued encroachment of the whites, and to subsist on goods provided from an appropriation amounting to $2\frac{1}{2}$ cents per capita per diem. During the summer a drunken Indian of the tribe shot and wounded two teamsters; the excitement and bitter feeling caused by his arrest on 23rd November resulted in the killing of an agency employee. Troops were called for, and the murderer was pursued, captured, tried, and executed. This so increased the excitement of the Indians that, fearing what was assumed to be threatening demonstrations, the troops surrounded and captured two Bannock camps in January 1878; but most of the Indians were afterwards released. On account of insufficient food the Bannocks left the reservation in the spring and went to Camas prairie, where they killed several settlers. A vigorous campaign under General Howard resulted in the capture of about a thousand of them in August, and the outbreak came to an end after a fight, 5th September, at Clark's Ford, where twenty Bannock lodges were attacked, and all the women and children killed.

Bannock outbreak.

After the close of the Sioux outbreak of 1876–77 the Northern Cheyennes, numbering 937, who participated with the Sioux in that rebellion, were sent to Indian Territory. Early in September 1878 about 300 of these Indians, dissatisfied with their new quarters, left the reservation, determined to rejoin the Sioux. In passing through Kansas they killed more than forty whites, and committed other outrages. They were pursued, and 150 were captured and confined at Fort Robinson, Nebraska, whence it was decided to return them to Indian Territory, a plan to which the Indians refused to agree. After starving and freezing for several days, they made a desperate attempt to escape in June 1879, when nearly all were killed. The survivors were sent back to Indian Territory.

In July 1879 about 100 men of the White River Agency, Colorado, roamed from their reservation into southern Wyoming to hunt. During this time some forests were fired by railway tiemen, resulting in great loss of timber, and calling forth complaint against the Indians, who were ordered to remain henceforth on their reservation. In September the agent, Meeker, was assaulted after a quarrel with a petty chief, and requested military aid, which was granted. Orders were later issued for the arrest of the Indians charged with the recent forest fires, and Major Thornburgh was sent with a force of 190 men. Suspecting the outcome, the Indians procured ammunition from neighbouring traders, and informed the agent that the appearance of the troops would be regarded as an act of war. On 20th September Thornburgh's detachment was ambushed, and their leader and thirteen men were killed. The command fell back. On 2nd October a company of cavalry arrived, and three days later Colonel Merritt with 600 troops reached the scene. At or near the agency the bodies of Meeker and seven employees were found; all but one of the agency buildings had been rifled and burned. The conflict was soon ended, mainly through the peaceful attitude and influence of chief Ouray.

Ever since they have been known to history the various bands of Apaches have been hostile in character; and although some of their raids have seemingly been unprovoked, the most serious outbreaks in modern times have been attributable to mismanagement on the part of the civil authorities. The most important series of outbreaks during this period was by the Chiricahua band under Cochise, and later Victorio, who, together with 500 Mimbreños, Mogollones, and Mescaleros, were assigned, about 1870, to the Ojo Caliente reserve, New Mexico. Cochise, who had repeatedly refused to be confined within reservation limits, fled with his band, but returned in 1871, at which time 1200 to 1900 Apaches were on the reserve. Complaints by neighbouring settlers caused their removal to Tularosa, some distance north-westwards, but a thousand fled to the Mescalero reserve on the Pecos river, while Cochise left on another raid. Efforts of the military agent in 1873 to compel the restoration of some stolen cattle caused all (then numbering 700) again to decamp, but they were soon captured. Following the wishes of the Indians, they were returned to Ojo Caliente in 1874. Soon afterwards Cochise died, and the Indians began to show such interest in agriculture that by the following year there were 1700 Apaches at Ojo Caliente, and no depredations were reported. In 1876 the Chiricahua reservation in Arizona was abolished, and 325 of the Indians were removed to the San Carlos agency; others joined their kindred at Ojo Caliente, while some either remained in the mountains of their old reservation, or fled across the Mexican border.

Apaches.

This removal of Indians from their ancestral homes was in pursuance of a "policy of concentration." The cost of the experiment is difficult to estimate; the expense of the campaigns which followed during the next ten years of warfare amounted to millions of dollars, while fortunes were lost in the destruction of property, and hundreds of lives were sacrificed on both sides. This policy was thoroughly tested in the Chiricahua removal in Arizona, for in April 1877 Geronimo and other chiefs, with the remnant of the band left on the old reservation, and evidently the Mexican refugees, began depredations in southern Arizona and northern Chihuahua; but in May 433 were captured and returned to San Carlos. At the same time, the policy of concentration was applied to the Ojo Caliente Apaches of New Mexico, who were making good progress in civilized pursuits, but when the plan was put in action only 450 of the 2000 Indians were found, the remainder forming into predatory bands under Victorio. In September 300 Chiricahuas (mainly of the Ojo Caliente band) escaped from San Carlos, but surrendered after many engagements. These were returned to Ojo Caliente, but they soon ran off again. In February 1878 Victorio surrendered, in the hope that he and his people might remain on their former reservation. Instead of this, another attempt was made to force the Indians to go to San Carlos, with the same result. In June the fugitives again appeared at the Mescalero agency, and arrangements were at last made for them to settle there; but the civil authorities finding indictments against Victorio and others, charging them with murder and robbery, this chief with his few immediate followers, and some Mescaleros, fled from the reserve and resumed marauding. There was the usual call for an increased force of military, but the skirmishes in which they were engaged with the Chiricahuas met with remarkable success for the latter, while seventy settlers were murdered during a single raid. Thus encouraged, Victorio was joined before April 1880 by 350 Mescaleros and Chiricahua refugees from Mexico, and the repeated raids which followed struck terror to the inhabitants of New Mexico, Arizona, and Chihuahua. On 13th April 1000 troops under Colonel Hatch arrived, and these were later greatly augmented. Victorio's band was frequently encountered by overwhelming forces, and although supported during most of the time by only 250 or 300 warriors, this warrior usually inflicted severer punishment than he suffered. In these raids 200 citizens of New Mexico, and as many more of Mexico, were killed. At one time the band was virtually surrounded by a force of over 2000 cavalry and several hundred Indian scouts; but Victorio eluded capture and fled across the Mexican border, where his bloody campaign was continued. Pressed on both sides of the international boundary, and at times harassed by American and Mexican troops combined, Victorio finally suffered severe losses and his band became divided. In October 1880 Mexican troops, under Colonel Terrazas, encountered Victorio's party, comprising 100 warriors, with 400 women and children, at Tres Casillos. The Indians were surrounded and attacked in the evening, the fight continuing throughout the night. In the morning the ammunition of the Indians became exhausted, and although rapidly losing in strength, the remnant refused to surrender, until Victorio, who had been wounded several times, finally fell dead. This disaster to the Indians did not quell their hostility. Victorio was succeeded by Nana, who collected the divided force, received reinforcements from the Mescaleros and the San Carlos Chiricahuas, and between July 1881 and April 1882 continued the raids across the border, but was again driven back into Chihuahua.

The policy of concentration.

While these hostilities were in progress in New Mexico and

Chihuahua, the Chiricahuas of San Carlos were striking terror in the settlements of Arizona. In 1880 Juh and Geronimo, with 108 followers, were captured and returned to San Carlos, and in June 1881 trouble arose among the White Mountain Apaches on Cibicu Creek, owing to a medicine-man named Nakaidoklini, who claimed the power to revive the dead—for a consideration. Being liberally compensated, the prophet began the incantations that were to fulfil his predictions. His adherents waited the resurrection until August, when Nakaidoklini avowed that the dead refused to return because of the presence of whites. As affairs were assuming a serious aspect, the prophet's arrest was ordered. He surrendered quietly, but as the troops were making camp the scouts and many other Indians opened fire on them. After a sharp fight Nakaidoklini was killed and his adherents were repulsed. Skirmishes continued during the next day, but the troops were reinforced, and the Indians soon surrendered in small bands. Two chiefs, known as George and Bonito, who had not been engaged in the White Mountain troubles, surrendered to General Wilcox, 25th September, at Camp Thomas, but were paroled. On 30th September Colonel Riddle was sent to bring these chiefs and their bands back to Camp Thomas; but they became alarmed and fled to the Chiricahuas, seventy-four of whom left the reserve, and, crossing the Mexican border, took refuge with the late Victorio's band in Chihuahua. During the same year Nana (Victorio's successor) made one of his bloody raids from across the line, and in September Juh and Nahchi, with a party of Chiricahuas, again fled from the reservation, and were forced by the troops into Mexico, where, in April 1882, they were joined by Geronimo and the rest of the hostile Chiricahuas of San Carlos, with Loco and his Hot Springs band.

Depredations in Arizona.

The depredations committed in northern Chihuahua under Geronimo and other leaders were perhaps even more serious than those within the limits of the United States. In March 1883 Chato, with twenty-six followers, made a dash into New Mexico, murdering a dozen persons. Meanwhile the white settlers on the upper Gila consumed so much of the water of that stream as to threaten the Indian crops; then coal was discovered on the reservation, which brought an influx of miners; and investigation by the Federal grand jury of Arizona on 24th October 1882, showed that, in the management of Indian affairs on San Carlos reservation, "fraud, peculation, conspiracy, larceny, plots and counterplots seem to be the rule."

Meanwhile General Crook had been assigned the task of bringing the raiding Apaches to terms by co-operating with the Mexican troops of Sonora and Chihuahua. In May 1883 Crook crossed the international boundary to the headwaters of the Rio Yaqui with 50 troops and 163 Apache scouts. On the 13th the camp of Chato and Bonito was discovered, and attacked with some loss. By employing two captives as emissaries, communication was soon had with the others, and by 29th May 354 Chiricahuas had surrendered.

On 7th July the War Department assumed police control of the San Carlos reservation, and on 1st September the Apaches were placed under the entire charge of General Crook, who began to train them in the ways of civilization, with such success that in 1884 over 4000 tons of grain, vegetables, and fruits were harvested. In February 1885 Crook's powers were curtailed; this led to conflict of authority between the civil and military officers, but before matters could be adjusted half the Chiricahuas left the reservation in May and fled to their favourite haunts. Troops and Apache scouts were again sent forward, and many skirmishes took place, but the Indians were wary, and again Arizona and New Mexico were thrown into a state of excitement and dread by raids across the American border, in which seventy-three white people and many friendly Apaches were killed.

In January 1886 the American camp, under Captain Crawford, was attacked through misunderstanding by Mexican irregular Indian troops, resulting in Crawford's death. By the following March the Apaches became tired of the war and asked for a parley, which Crook granted as formerly; but before the time for the actual surrender of the entire force arrived the wily Geronimo changed his mind, and with his immediate band again fled beyond reach. This led to severe criticism of Crook's policy. He was consequently relieved, at his own request, in April, and to General Miles was assigned the completion of the task. Geronimo and his band finally surrendered, 4th September 1886, and with numerous friendlies were sent to Florida as prisoners. They were later taken to Fort Sill, Oklahoma, where, now numbering 298, they are making progress towards civilization. Some of the malcontents were never captured, but remained in the mountains, and as late as November 1900 manifested their warlike propensity in a fight with Mormon settlers; but Apache hostility in Arizona and New Mexico has entirely ceased.

No further trouble of a serious nature was experienced among the Indians until 1890, in which year occurred the so-called Sioux outbreak, which culminated in the tragedy of Wounded Knee. This difficulty was due in part to a religious excitement, known as the ghost-dance craze, which had its origin in the dream of a Paiute Indian of Nevada, and which spread from the Canadian boundary to Oklahoma; and secondarily, to the failure on the part of the Government to fulfil its treaty stipulations in the matter of rations. By October 1890 it was reported that some of the Sioux, under the influence of the noted Sitting Bull, had become excited over the prediction of an approaching millennium, or "return of the ghosts," when the white people would be annihilated; but to bring about this result the Indians must believe and organize the ghost-dance. By 13th November, some of the agents having lost control owing to the excitement caused by the new doctrine, the War Department assumed authority. On 15th November the agent at Pine Ridge became panic-stricken and sent for troops, and soon there were nearly 3000 soldiers in the Sioux country. The appearance of the military was a signal for the flight to the Bad Lands of 1500 Indians, who were soon followed by others, until 4000 had left their agencies. As Sitting Bull still continued the ghost-dance, his arrest was planned. On 15th December Indian police surrounded his house, when he agreed to surrender, but the gathering of his immediate followers encouraged him to change his mind; he defied arrest; one of his friends shot a policeman, and Sitting Bull himself, his son, and seven others were killed in return, the Indian police losing six. The killing of Sitting Bull resulted in the stampede of another party, but they were overtaken. An attempt to disarm them on the morning of 29th December at Wounded Knee Creek, a few miles from the Pine Ridge agency, led to a hand-to-hand encounter, in which nearly every Indian warrior and a number of their women and children fell. The women and children who survived the first volleys were pursued by the troops for two miles, their dead bodies littering the way. Of the 370 members of Big Foot's band, including all ages and both sexes, about 300 were killed. This broke the backbone of the outbreak. The remaining Indians surrendered 16th June 1891, and thus was ended what, in all probability, will be the last experiment in warfare by the Sioux.

"Wounded Knee" tragedy.

The last Indian trouble occurred among the hitherto friendly Pillager Chippewas of Leech Lake, Minnesota. In 1889 the Chippewas ceded large tracts of valuable pine land on the representation that the sale of the timber would yield them a large fund. In the course of time three boards of appraisers were appointed, their expenses, payable from the Indian funds, amounting to $280,000, the only return which the Indians received being an appraisal of their timber at from a fourth to a half of its value. Then authority was granted to white lumbermen to dispose of only "dead and down timber," but green timber was cut in enormous quantities at the expense of the Indians, while groves were burned to bring the trees nominally under the head of "dead" timber. In further justification of their final protest against white interference, it was officially announced that wholesale arrests of the Chippewas were made for the sake of the fees which accrued to the state officials, and that Indians had been helped to obtain whisky by those who arrested them for using it. It was an arrest of this sort in September 1898 that led to the rescue of the prisoners by a number of their relatives, the result of which was the issuing of warrants against the Indians who had thus defied the law. Councils were held by the Chippewas, at which the decision was reached not to surrender the men wanted by the court officials. On 3rd October, special Government agents having reached the scene, a general council was called, with assurance that none who attended would be arrested. Meanwhile troops had arrived to quell any threatened disturbance and to aid the sheriff in making the arrest. The accidental discharge of a gun by a soldier on 5th October caused some Indians secreted in the woods to open fire, killing Major Wilkinson and several soldiers. On the following day additional troops arrived, another council was held, and difficulties came to an end with the arrest and moderate punishment of most of those for whom warrants had previously been issued.

Chippewa disturbance.

Such is the history of the strife between the Indian and the white man during the last quarter of the 19th century. It has been seen that, in addition to delays on the part of the United States Congress in fulfilling its treaty obligations, the cause of many of the outbreaks was due to the fact that the Indian had too often failed to receive the sympathy which his savage state should have inspired in his civilized neighbour; again, as has been officially recognized, corrupt and ignorant agency employees frequently promoted discontent among their charges, while changing administrations often caused changes in the Indian service at times when men of experience were greatly needed. For these and other reasons there was for many years no definite policy on the part of the

United States Government for solving what became known as the Indian question. Indeed, as late as 1876 it was officially declared that "the fundamental difficulty in our relations hitherto with Indians has been the want of a well-defined, clearly-understood, persistent purpose on the part of the Government." Nevertheless, it was not until 1887 that any definite plan for the civilization of the Indian was adopted, although much had been accomplished towards his education. At one time the policy was to concentrate all the Indians within the limits of the United States on three great reservations, an expansion of the plan adopted earlier in the century, which set aside for the use of the eastern Indians the former "Indian country," which in after years became restricted to the Indian Territory. The sentiment in regard to great reservations, however, gradually weakened, until in 1878 it was proposed to concentrate the Indians on smaller reservations, "where they might be more readily protected in their property rights," their vacated lands to be sold for their benefit. But gradually a feeling against the entire reservation system arose, and grew in strength from year to year, until finally definite action was taken by Congress 8th February 1887, which has had greater effect than any other towards dissolving tribal relations. This was the enactment of the "land severalty" law, which, as amended in 1890, provides for the survey of reservations and the allotment to each person of a tract ranging from 40 to 160 acres. The law also provides for doubling the allotments when the land is found valuable only for grazing, and the sale of the remainder to white settlers. Provision is also made that after receiving such land allotments the Indians are declared citizens. Allotments in severalty had been made to various Indians under treaty provisions and congressional enactments, but it is under the law of 1887 that most of the allotments have been made. To 30th October 1900, 6,736,504 acres had been allotted to 56,996 Indians. With the general allotment law in operation, the way was clear for the final abolishment of the reservation and agency systems. All subsequent laws and treaties have had these ends in view.

The Indian question.

Land Severalty law, 1890.

Ever since the establishment of the Government, interest in the education of the Indians has been felt, and as treaties were made and ratified, funds were sometimes provided for this purpose. Reservation boarding-schools were founded in 1865; in 1870 Congress appropriated $100,000 for Indian education. In 1877, $20,000 was appropriated for the support of Indian schools; and in 1878, $30,000 was granted for that purpose. In the latter year 103 Indian children were received at Hampton Institute, Virginia; and on 1st November 1879, Lieutenant R. H. Pratt opened an Indian school at Carlisle Barracks, Pennsylvania, with 158 children. This was the beginning of the now well-known Carlisle school, which in 1900 had an enrolment of 1080 Indian pupils. The Indians are given a common school and industrial education, and an effort is made to equip each pupil with means for self-support. Unfortunately, many of the Indians on returning to their homes, owing to the lack of demand for their acquired knowledge, lapse into the primitive ways of their fathers. One of the features of the Carlisle school is its "outing system," by which pupils are employed by farmers and others as labourers, domestic servants, &c. In 1890, 807 youths were employed during the summer, and 316 during the winter season. The earnings of the pupils during this year amounted to $27,255. One of the objects of establishing the school at Carlisle was its remoteness from tribal influence and its proximity to civilization, where constant object-lessons might be taught. For the same reason other non-reservation schools were established at various points between 1880 and 1898, so that by June 1900 25 such schools were in operation, with 7430 pupils enrolled. In addition, there were 81 reservation boarding-schools with an enrolment of 9604, and 147 day schools with 5090 pupils. Contracts are also made with public schools in various localities; in these there are 246 children. In the boarding-schools of all classes the average attendance increased from 3077 in 1882 to 17,708 in 1900; in the day schools the increase was from 1637 to 3860 during the same period. In 1900 there were also 884 children in various contract schools, mainly sectarian in character. In addition, there are 22 reservation mission schools, with an average attendance of 946 boarding pupils and 193 day pupils.

Education.

In the education of its Indian wards Congress has been liberal. From 1877, when the first regular appropriation of $20,000 for Indian schools was made, until 1900–1, when $3,087,367 was allotted for Indian schools alone, more than $35,000,000 has been expended in this direction. Of the estimated 268,000 Indians within the limits of the United States, 45,270 (exclusive of school-children) are supported entirely by rations issued at public expense, while 12,570 are partially supported. Almost without exception these Indians formerly gained their livelihood through bison-hunting. Apart from the cost of supporting these dependent people, which amounts to about $1,250,000 per annum, the ration system tends to encourage idleness, and thus to retard advancement towards enlightenment. Again, mainly in pursuance of treaty stipulations from time to time during the century, but also through interest on trust funds (amounting to $33,317,955) and moneys derived from grass-land leases, &c., annuities are paid to Indians, which range in sums per capita from 50 cents to $255 per annum; these annuitants number 63,495, and the aggregate sum paid them in 1900 was $1,507,542. Owing to the evils arising from the prospective payments from time to time, the present policy is gradually to extinguish the trust funds, just as the policy for years has been to dissolve the reservation system by allotting lands in severalty.

Federal support.

While the Government has been responsible for many Indian revolts and their terrible consequences, it must not be assumed that the United States has been illiberal in its support of its Indian wards, for the total expenditure on account of the Indian service (exclusive of the vast sums expended in the prosecution of warfare against the tribes) from 1789 to 1900 has reached the enormous sum of $368,358,217, although a goodly proportion of this sum has been devoted to the purchase of tribal lands.

In order to render an idea of the progress of the United States reservation Indians in the pursuits of civilization, the following statistics for 1899 are given:—Land cultivated, 334,666 acres; land under fence, 1,657,143 acres; corn raised, 1,386,977 bushels; wheat, oats, and barley raised, 1,832,507 bushels; vegetables raised (exclusive of melons and pumpkins), 445,935 bushels; hay produced, 250,231 tons; lumber sawn, 5,917,000 feet; timber marketed, 68,678,795 feet; wood cut, 91,023 cords; horses, mules, and asses owned, 298,277; cattle owned, 325,898; swine owned, 50,216; sheep owned, 1,100,912; goats owned, 257,445; domestic fowls owned, 222,047; earnings from freightage, $91,768; value of products of labour sold, $1,324,103.

Current progress.

The total number of Indians in the United States in 1890 was 273,607; in 1900 it was 266,760. In 1890 the number of "Indians

not taxed," that is, of Indians living in tribal relations, was 189,447; in 1900 it had fallen to 129,518. In 1890 the number of "Indians taxed," that is, of Indians found living among the general population, and therefore liable to taxation, was 84,160; in 1890 the number had grown to 137,242, a large increase, especially in view of the fact that the total number of Indians had somewhat decreased. The states and territories which contained the largest numbers of Indians in 1900 were as follows:—Indian Territory, 52,500; Alaska, 29,536, including 2499 of mixed parentage (descendants of native Indians and Russians); Arizona, 26,480; South Dakota, 20,225; California, 15,377; New Mexico, 13,144; Oklahoma, 11,945; Montana, 11,343; Washington, 10,039; Minnesota, 9182; Wisconsin, 8372.

The following is a list of the principal tribes within the limits of the United States, Canada, and Mexico. Mexico has no reservation system, its numerous Indians (statistics of the population of whom are untrustworthy) being regarded as citizens of the Republic:—

Indian Tribes of America North of Mexico with Population of 500 *or more.*

Tribe.	Stock.	Situation and Population.
Abnaki	Algonquian	1182 in Canada, 625 in Maine. Total 1807.
Aht	Wakashan	Includes several small divisions on Vancouver Island and the Makah in Washington. Population 3600.
Algonkin	Algonquian	400 in Ontario, about 4400 in Quebec. Total 4800.
Apache	Athapascan	298 Chiricahua prisoners at Fort Sill, Oklahoma; 647 Coyoteros on White Mountain reservation, Arizona; 831 Jicarillas and 443 Mescaleros in New Mexico; 176 Kiowa Apaches (Nadiishañdina) in Oklahoma; 2155 "San Carlos" Apaches and 1849 "White Mountain" Apaches on White Mountain reservation, Arizona; 30 children at Carlisle school. Total 6429.
Arapaho	Algonquian	976 in Oklahoma, 806 in Wyoming, 5 children at Carlisle. Total 1787.
Assiniboin	Siouan	1323 in Montana, 1245 in Canada, 9 children at Carlisle. Total 2577.
Auk	Koluschan	640 in Alaska.
Bannock	Shoshonean	513 (including others) in Idaho, 4 children at Carlisle. Total 517.
Bellacoola	Salishan	About 2500 (including Heiltsuqs of Wakashan family) in British Columbia.
Blackfeet (Siksika)	Algonquian	1060 in North-west Territories, Canada. See Bloods, Piegans.
Bloods	Algonquian	1247 in North-west Territories, Canada. (A Blackfoot division.)
Caddo	Caddoan	About 500 in Oklahoma.
Cariboo-eaters (Ethen-eldeli)	Athapascan	About 1200 east of Lake Athabasca, Canada.
Caughnawaga	Iroquoian	2005 in Quebec.
Cayuga	Iroquoian	About 1075 in Ontario, 170 in New York, about 164 in Indian Territory, 4 children at Carlisle. Total 1413.
Cherokee	Iroquoian	1363 in North Carolina, 29,511 in Indian Territory (excluding 4000 negroes and intermarried whites). Total 30,874.
Cheyenne	Algonquian	2071 in Oklahoma, 1363 in Montana, 61 in South Dakota, 22 children at Carlisle. Total 3517.
Chickasaw	Muskhogean	About 5000 in Indian Territory (excluding about 4000 freedmen and intermarried whites).
Chippewa	Algonquian	26 in Kansas, 3480 in Michigan, 3304 at Leech Lake, and 4619 at White Earth, Minnesota; 2551 in North Dakota; 4982 in Wisconsin, 73 children at Carlisle, 11,862 in Ontario, about 4117 in Manitoba, about 1340 in North-west Territories. Total 36,354.
Chippewaian	Athapascan	About 3000 in vicinity of Lake Athabasca.
Choctaw	Muskhogean	About 15,000 in Indian Territory (excluding 4250 freedmen and intermarried whites).
Comanche	Shoshonean	1490 under Kiowa agency, Oklahoma.
Cree	Algonquian	3000 in Manitoba, 7000 under agencies, and about 5000 roving in North-west Territories. Total 15,000.
Creeks	Muskhogean	About 8700 in Indian Territory (excluding about 6000 freedmen and intermarried whites).
Crows (Absaroka)	Siouan	1962 under Crow agency, Montana.
Delawares	Algonquian	About 1000 with the Cherokees in Indian Territory, 95 in Oklahoma, about 753 (including Munsees and "Moravians") in Ontario, 26 in Kansas, 60 in Wisconsin, 40 with the Iroquois in New York. Total 1974.
Dogribs	Athapascan	About 1000 between Great Slave and Great Bear Lakes, Canada.
Eskimo	Eskimoan	About 20,000 Innuit in Alaska, about 1100 Eskimo in Baffin Land, about 2000 in Labrador, about 11,000 in Greenland. Total 34,100 (estimated).
Flatheads	(Mixed)	1816 under Flathead agency, Montana (includes Pend d'Oreilles and Kutenais).
Grosventres (Atsina)	Algonquian	619 under Fort Belknap agency, Montana. Distinct from the Hidatsa or Minitari, a Siouan tribe, also called Grosventres, numbering 459 on Fort Berthold reservation, North Dakota.
Haida	Skittagetan	2500 in British Columbia, including 630 under North-west Coast agency.
Hares or Kawcho-tinneh	Athapascan	600 on Mackenzie, Anderson, and MacFarland Rivers, Canada.
Hidatsa	Siouan	See Grosventres.
Hopi or Moki	Shoshonean	About 1800 in north-eastern Arizona.
Iroquois	Iroquoian	See under the tribal names.
Kaibabits	Shoshonean	600 (including Shivwits) in Nevada, 470 in Utah. Total 1070.
Kickapoo	Algonquian	246 in Kansas, 234 in Oklahoma, about 200 in Mexico. Total 680.
Kiowa	Kiowan	1074 in Oklahoma.
Klamath	Lutuamian	731 in Oregon, 673 in California. Total 1404.
Kutenai	Kitunahan	491 in British Columbia, 450 in Montana. Total 941.
Kwakiutl	Wakashan	1597 (including 291 Lekwiltok) in British Columbia.
Loucheux or Kutchin	Athapascan	About 4400 on lower Mackenzie River and in Alaska.
Menomini	Siouan	1389 under Green Bay agency, Wisconsin.
Miami	Algonquian	439 in Indiana, 101 in Indian Territory. Total 540.

Tribe.	Stock.	Situation and Population.
Micmac	Algonquian	634 in Quebec, 960 in New Brunswick, 2018 in Nova Scotia, 308 on Prince Edward Island. Total 3920.
Mission Indians	Shoshonean Yuman	Under Mission Tule agency, California.
Missisaga	Algonquian	764 in Ontario.
Mohave	Yuman	1962 under Colorado River agency, Arizona.
Mohawk	Iroquoian	3103 in Ontario and Quebec.
Monsoni	Algonquian	4000 (including Maskegon) in eastern Rupert Land.
Montagnais	Algonquian	1793 in Quebec; distinct from a group of Athapascan tribes known under the same name.
Munsee	Algonquian	See Delawares.
Nahani	Athapascan	700 on Stickeen river and Connolly lake, B.C.
Nascapi	Algonquian	About 2800 on lower St Lawrence, Quebec.
Nasqa or Nass	Chimmesyan	2781 in British Columbia.
Navaho	Athapascan	About 20,000 on reservation in New Mexico and Arizona.
Nez Percés or Chopunnish	Shahaptian	1639 in Idaho, 127 in Washington. Total 1766.
Okanagan	Salishan	573 in Washington, about 900 in British Columbia. Total 1473.
Omaha	Siouan	1157 on Omaha and Winnebago reservation, Nebraska.
Oneida	Iroquoian	1941 in Wisconsin, 255 in New York, 1068 in Ontario. Total 3264.
Onondaga	Iroquoian	551 in New York, 385 in Ontario. Total 936.
Osage	Siouan	1765 under Osage agency, Oklahoma.
Ottawa	Algonquian	4000 in Michigan, 165 in Indian Territory, 1000 in Canada. Total 5165 (estimated).
Paiute	Shoshonean	1415 under agencies and 6815 wandering in Nevada, 200 in California, 200 in Oregon, 100 in Utah. Total 8730, including Pahvant, Gosiute, &c.
Papago	Piman	1726 under agencies and 2046 wandering in Arizona, about 1000 in Sonora. Total 4772 (estimated).
Pawnee	Caddoan	664 in Oklahoma.
Piegan	Algonquian	1957 (including some Bloods and Blackfeet) in Montana, 519 in North-west Territories, Canada. Total 2476.
Pima	Piman	4260 in southern Arizona.
Pit River Indians	Palaihnihan	1573 (estimated) in northern California, 94 in Oregon. Total 1667.
Ponka	Siouan	567 in Oklahoma, 231 in Nebraska. Total 798.
Potawatomi	Algonquian	569 in Kansas, 77 in Michigan, 1618 in Oklahoma, 280 in Wisconsin, about 334 in Ontario. Total 2878.
Pueblos of New Mexico	Tanoan Keresan Zuñian	Excludes the Hopi. Acoma, 566; Cochiti, 355; Isleta, 1000; Jemez, 456; Laguna, 1143; Nambe, 98; Picuris, 96; Sandia, 77; San Felipe, 650; San Ildefonso, 150; San Juan, 378; Santa Ana, 300; Santa Clara, 248; Santo Domingo, 1015; Taos, 402; Tesuque, 84; Sia, 104; Zuñi, 1422; Pojoaque, 20; Hano (Arizona), 600 (?). Total 9164.
Puyallup	Salishan	555 in western Washington.
Sauk and Fox	Algonquian	522 in Oklahoma, 390 in Iowa, 78 in Kansas. Total 990.
St Regis Iroquois	Iroquoian	About 1171 in New York, 1351 in Quebec. Total 2522.
Seminole	Muskhogean	2900 (including 1450 freedmen) in Indian Territory, 575 in Florida. Total 3475.
Seneca	Iroquoian	165 with Cayugas in Indian Territory, 2812 in New York, 230 in Ontario. Total 3207.
Shawnee	Algonquian	674 in Oklahoma, 93 under Quapaw agency, and about 800 with the Cherokees in Indian Territory. Total 1567.
Shoshoni	Shoshonean	1437 in Idaho (including Sheep-eaters), 296 in Nevada, 842 in Wyoming. Total 2575.
Sicanni	...	See Tsekehne.
Sioux or Dakota:		
Santee	Siouan	1285 in Nebraska (includes Mdewakantons and Wahpekutes), about 54 in North Dakota, 907 Mdewakantons in Minnesota, 161 Mdewakantons and Wahpekutes in North-west Territories. Total 2407.
Sisseton	...	1884 in South Dakota (includes Wahpetons), about 863 Sissetons, Wahpetons, and Cutheads (Yanktonnais) in North Dakota, 283 Wahpetons and Sissetons in North-west Territories. Total 3030.
Yankton	...	1701 in South Dakota, about 126 in North Dakota. Total 1827.
Yanktonnais	...	1222 in Montana, 3575 (including about 1000 Uncpapa and Sihasapa Blackfeet) in North Dakota, 1047 in South Dakota. Total 5844.
Teton	...	2552 Two-kettles, Sihasapa Blackfeet, Sans Arcs, and Minneconjous under the Cheyenne River agency, South Dakota; 6452 Oglalas under the Pine Ridge agency, South Dakota; 4862 Upper Brulés, Loafers (Oglalas), Wazhazhas (Oglalas), Two-kettles, and Lower Brulés under the Rosebud agency, South Dakota; 472 Lower Brulés under the Lower Brulé agency, South Dakota. Total 14,338.
Miscellaneous	...	52 children at Carlisle, 172 at Muscowpetung, and 60 roving in North-west Territories. Total 284.
Slavés	Athapascan	About 1000 west of Great Slave Lake and Mackenzie River.
Spokan	Salishan	91 in Montana, 695 in Washington. Total 786.
Thompson River Indians (Ntlakyapamuq)	Salishan	About 4500 in British Columbia.
Tsekehne	Athapascan	About 1400 (including 500 Tsekehnes proper) about Canadian Rockies, 700 Beavers about Peace River, 203 Sarsis east of Rockies, 51° N. Total 2303.
Tuscarora	Iroquoian	378 on Tuscarora reserve, New York; 365 in Ontario. Total 743.
Ute	Shoshonean	998 Moaches, Capotes, and Wiminuchis in Colorado; 471 Uintas, 851 Uncompahgres, and 380 White River Utes in Utah. Total 2700.

Tribe.	Stock.	Situation and Population.
Walapai	Yuman	611 on Colorado river, north-western Arizona.
Wallawalla	Shahaptian	529 at Umatilla agency, Oregon.
Wichita	Caddoan	956 (including affiliated bands) in Oklahoma.
Winnebago	Siouan	1129 in Nebraska, 1447 in Wisconsin. Total 2576.
Wyandotte or Huron	Iroquoian	449 in Quebec, 6 in Ontario, 344 in Indian Territory. Total 799.
Yakima	Shahaptian	2000 (estimated) in Washington; includes about 950 Yakima proper and numerous small tribes.
Yavapai	Yuman	702 under the San Carlos agency, Arizona. Officially called Apache Mohaves.
Yellowknives (T'atsan-ottine)	Athapascan	About 500 north-east of Great Slave Lake, Canada.
Yuma	Yuman	707 under the Mission Tule agency, California; remainder under the San Carlos agency, Arizona.

(F. W. H.)

Indian Territory, situated in central southern United States, between 33° 25′ and 37° N. and 94° 25′ and 98° W., bounded on the N. by Kansas, on the E. by Missouri and Arkansas, on the S. by Texas, and on the W. by Oklahoma Territory. Without organized territorial form of government, it comprises for the most part the lands of the Cherokee, Creek, Seminole, Choctaw, and Chickasaw tribes of Indians, known as the Five Civilized Tribes, whose possessions occupy 31,060 square miles of the 31,400 square miles contained in the Territory. The balance, located in the north-east corner, is occupied by Indians of the Quapaw Agency, composed of remnants of eastern Shawnees, Miamis, Ottawas, Peorias, Quapaws, Senecas, Cayugas, and Wyandottes, and a few scattered members of other tribes. The Territory was originally much larger, and included all of Oklahoma and a portion of Arkansas. It is divided geologically into, first, the Wichita mountain region of Appalachian-like folds of Palæozoic strata, chiefly Carboniferous, with some older Palæozoic rocks on the southern border, including a field of granite rocks near Tishomingo. Within this field are found building stones of sand and granite and limestone, also Coal Measures on the northern side and asphalt on the southern. Secondly, there is the Ozark Plateau, a region of nearly horizontal and greatly dissected Carboniferous and Silurian rocks, containing limestone, zinc, and lead. Then, thirdly, there are the Prairie Plains, which are a continuation of similar plains in southern Kansas, being nearly horizontal Carboniferous rocks, which contain coal and evidence of petroleum. The fourth division comprises southern prairies, which are the northern edge of the Cretaceous rocks of the Texas region, a country of sands, limestones, and marls, containing agricultural lands and also evidences of artesian water. The topography is varied, the eastern part being mountainous and rugged, the middle part generally rolling or hilly, and the western part largely prairie, with the exception of a group of hills in the central portion of the Chickasaw Nation, known as the Arbuckle Mountains. Woodland, composed of many varieties of oak and (along streams) of cottonwood, elm, pecan, &c., is well scattered over the entire area; but the heaviest timber is confined to the eastern half, where, in addition to the trees mentioned, are found yellow pine and cedar on high ground, and walnut on streams, in sufficient quantity to make them of commercial value. The oaks are used only for fuel and railway ties. The principal streams are the Arkansas, Canadian, Grand, Verdigris, Illinois, Deep Fork, Washita, and Red, flowing through valleys which are generally broad and fertile, producing excellent crops. The highest elevation reached above sea-level is about 3000 feet, and the lowest about 350 feet. The climate is similar to that of northern Georgia, with a mean annual rainfall of about 36 inches. Of the wild animals and birds to be found may be mentioned black bear, cougar, wolf, coyote, fox, deer, squirrel, rabbit, prairie dog, turkey, prairie chicken, quail, eagle, hawk, and buzzard.

The first settlement of Indian Territory was by Creek Indians in 1827, and certain lands were set aside for their use in 1829. It formed a portion of the territory embraced in the Louisiana purchase in 1803. To enable the whites to obtain possession of the Indian lands in the southern states east of the Mississippi, these lands in what is now Indian Territory were set aside, and in 1830, under President Jackson, the removal of the Indians was ordered. The Cherokees, Creeks, Choctaws, and Chickasaws began their removal about 1833, but the Seminoles were not removed until 1845. The various tribes of the Quapaw Agency were removed at different times. Much of their original holdings has been sold to meet the demands of white settlement.

The Five Civilized Tribes are called Nations, and occupy separate land areas covered by patents. Each has an independent elective form of government, similar to that of the states of the United States, and they elect governors, legislators, judges, and minor officials. A United States judicial system is provided, divided into three districts; and under recent enactment by Congress these courts have entire jurisdiction, the Indian courts being set aside. Under United States law no alcoholic liquors are permitted to be sold in the Territory. The Indians of the Quapaw Agency are under the care of a United States agent, each tribe having its chief, and they have long since taken their lands in severalty. The Five Civilized Tribes are self-supporting, and they are in charge of a United States agent at Muscogee, his relations with the Five Tribes being regulated by the treaties, and by instructions from the Secretary of the Interior. Ample funds, derived from sale of lands, are held in trust for the several nations, upon which interest is paid to them annually.

There was a large increase in the acreage cultivated of all farm products during the closing years of the 19th century, but no statistics have been gathered. The principal products are cotton, corn, oats, wheat, potatoes, and hay. The extensive prairies furnish pasturage for a large number of cattle, some of which are raised in the Territory, but the larger portion is shipped in from Texas to fatten for northern markets. Some horses and swine are raised, and a few sheep. There are 1260 miles of railway in the Territory, traversing it in all directions, making nearly every section accessible by rail. In 1900 the number of manufacturing establishments in the Territory (excluding 348 having a product of less than $500 each) was 789, with a total invested capital of $2,624,265. There were 135 salaried employees, and an average number of 1714 wage-earners. The added values of the products in the different establishments amounted to $3,892,181. There were 187 cotton-ginning establishments, with a capital of $572,475 and a product of $345,751; 61 flouring and grist mills, with a capital of $478,241 and a product of $1,198,472; 6 lumber and planing mills, with a capital of $265,683 and a product of $424,399; and 6 cotton-seed oil and oil-cake establishments, with a capital of $394,850 and products of $451,656.

The total population of Indian Territory in 1900 was 392,060, including 51,393 Indians not taxed. In 1890 the total population was 180,182. The population of the principal towns is as follows: Ardmore, 5681; Muscogee, 4254; South McAlester, 3479; Chickaha, 3209; and Durant, 2969. The capital of the Cherokee Nation is Talequah; of the Creek Nation, Okmulgee; of the Seminole Nation, Wewoka; of the Choctaw Nation, Tuskahoma; of the Chickasaw Nation, Tishomingo. There is no capital for the Territory. Of the total population in 1900, 208,952 (53·3 per cent.) were males and 183,108 (46·7 per cent.) were females; 387,202 were native-born, and 4858 (1·2 per cent.) were foreign-born; 302,680 were white and 89,380 coloured (22·8 per cent.), of whom 27 were Chinese, 36,853 negroes, and 52,500 were Indians. The death-rate in 1900 was about 13·4 per cent. The number of persons of school age (5 to 20 years) was 159,125. Out of 97,361 males of voting age 15,473 were illiterate (unable to write), of whom 8477 were white, 3776 negroes, and 3220 Indians.

Many of the Indians still use the Indian language, and the Cherokees have an alphabet, and print their laws, books, and newspapers in the Cherokee language. The Indians are well housed, cultivate farms, raise cattle, horses, and hogs, and compare favourably with their white neighbours in the adjoining states. There is a large number of churches and schools, well

attended. Many of the traditional customs are still retained, and ball games, dances, and other amusements and ceremonials are held. Many freed negroes and their descendants speak only the Indian language. These freedmen will have a share in the allotment of lands which is in progress. They are industrious and fairly well advanced, and in some of the tribes have occupied high positions, while some of them are possessed of considerable wealth. The full-blood Indians live as far as possible from the white settlements; and as the whites are numerous, the Indians have been crowded back into the wooded and mountainous regions, but those of the mixed blood are generally progressive and quite able to take care of their interests in their contact with the "non-citizens" or "intruders."

Under Indian laws, Indian citizens hold as much land as they desire, as long as it is occupied or used by them or their lessees. White men, or non-citizens, can obtain no land by purchase, but under the Indian system of leasing and permits these non-citizens have obtained the use of lands under lease from individual Indians and by paying for a permit or tax to the Indian government. The holdings thus made to white men are immense, both for grazing and cultivation; and in the towns there are many expensive buildings, the owners of which have no valid title to the land. In the next few years there will probably be a division of land in severalty. The subdivision surveys have been made, and town site surveys are in progress. When they are completed the lots will be appraised and sold. This division, and in fact all changes, have been bitterly opposed by the Indians who have leased the holdings, as also by the full-blood Indians. (C. H. F.)

INDO-CHINA, FRENCH.

DURING the last twenty years of the 19th century important changes took place in the Far East and the peninsula of Indo-China. The principal European Powers considerably extended their influence and increased their possessions in this region. In Indo-China, more particularly, great alterations were effected. The political condition of the country was entirely changed. In many parts its frontiers were rearranged. New areas were added to the French possessions, and treaties and agreements concluded between France and China and France and Siam. A partition of influence between France and Great Britain was also agreed upon. Explorations and numerous more or less careful surveys have made us acquainted with regions hitherto imperfectly known. The governmental organization, greatly modified, has now taken definite, and probably final, form. Physical conditions have improved, owing partly to the restoration of order and security to the country and the consequent growth of conditions favourable to the settling and cultivation of long-abandoned districts, and partly to the construction of roads, bridges, canals, and railways, and the investigation and exploitation of mineral wealth.

Geography.—The geographical denomination of French Indo-China includes Annam and Tongking, Cochin-China, Cambodia, and part of the Laos country. In 1900 the newly-acquired territory of Kwang-Chow-Wan, on the coast of China, was placed under the authority of the governor-general of Indo-China. Cochin-China, a geographical definition which formerly included all the countries in the Annamese empire—Tongking, Annam, and Cochin-China—now signifies only the French colony, consisting of the "southern provinces" originally conquered from Annam, having Saigon as its capital. In its entirety French Indo-China, the eastern portion of the Indo-Chinese peninsula, lies between 8° 30′ and 23° 25′ N. and 100° and 109° 20′ E. It is bounded on the N. by China, on which side the frontiers have been delimited; on the E. and S.E. by the Gulf of Tongking and the China Sea; on the S.W. and W. by a conventional line between Cambodia and Siam, thence by the right bank of the Mekong, which divides it from Siam and Burma. The configuration of the country is determined by two rivers of unequal importance and a continuous chain of mountains, an offshoot of the great Chinese group of Yunnan, which, making a double curve, forms an immense S. To the north and north-east of this chain the valley of the Song-Koi, or Red river, constitutes almost the whole of Tongking, of which its delta represents the most fertile and populous if not the largest portion. The small mountainous provinces of Lang-son, That Ké, and Kao-bang belong, however, geographically to the Si-Kiang basin. On the east the small province of Monkai, on the borders of Kwangtung, forms a little basin enclosed between the mountains and the sea; on the south the province of Thanhhoa, although crossed by the small river Song-ma, forms the extremity of the Red river delta and belongs to it, the two rivers being united at some distance from the sea by a natural channel formed by the junction of a northern branch of the Song-ma with a southern branch of the Song-Koi. The Red river descends from the mountains of Yunnan, rising near Tali-fu between deep and inaccessible gorges, and becomes navigable only on its entry into Tongking territory. Means have been taken to render it available to steam launches, and in consequence of an agreement between the State and the Compagnie des Correspondances Fluviales a service of steamers is provided from its mouth to Laokai. Near Hung-hoa the Red river receives its two chief tributaries, the Black river from the plateaux of the west—the land of the Muongs—and the Clear river, one of the largest of whose tributaries issues from the Ba-be lakes. The Black river is navigable for a considerable distance, the Clear river only from Tuyen Kwang. Between the basins of the Song-Koi and the Mekong the chain of mountains, crowned by tolerably extensive plateaux, covers, with its ramifications and transverse spurs, a vast extent of country as yet little known, although several trade-routes traverse it, thus placing the Laos country in communication with Tongking and Annam. In about 19° N. the mountain-ridge approaches the sea and runs parallel to the coast, presenting on its eastern side a steep declivity which encloses a narrow littoral, in places only a mile or two broad, between the base of its cliffs and the shore. This coast-belt constitutes the habitable and cultivable portion of Annam proper, and consists of alluvial matter accumulated at the mouths of mountain streams, and marshes and swamps enclosed between land and sea by sand ridges heaped up by wind and tide. The high valleys and plateaux originally belonged to the empire, the limits of which, although invaded and occupied by Siamese, formerly extended to the banks of the Mekong. The western slopes now form part of the French Laos possessions. The Mekong valley includes Laos, Cambodia, and the greater part of Cochin-China. The Mekong is one of the largest rivers of south-eastern Asia, having a course 1900 miles in length. The conditions of navigation have been sufficiently improved to permit of a fairly regular service of boats between Saigon and Pnom-penh, Kratie, Stung-treng, Khong, Pak-mun, and Vien-tian. At Khong a transshipment by means of a railway (3½ miles) gives access to the latter portion (which extends from Khong to Pak-mun or Savanna-kek) of the river's first course. The second reach, 310 miles in length, extends from Savanna-kek to Vien-tian. From Vien-tian to Luang-Prabang the river is practicable only for canoes. The mouths of the Mekong, six in number, communicate by means of a navigable canal with the Saigon river (fed by

the Donnai and the two Vaico rivers), which is navigable by the largest warships, rendering Saigon the most important natural port of Indo-China.

Geology.—The low-lying portions of Indo-China consist of two deltas—that of the Mekong, which comprises the lower parts of Cambodia and southern Cochin-China, and the Red river delta, or eastern Tongking. These deltas are composed of alluvium (generally silicious clay) deposited by the rivers. The mountains from which this soil is derived are granitic in formation, the framework being almost always schists of ancient date, dislocated, folded, and occasionally rounded into hills 1000 to 1300 feet in height, belonging to the Devonian period. Above these schists lie—more especially in the north and south of Tongking—marbles and other highly crystalline limestones, upon which rest, unconformably in places (Nongson, Ke-bao, Hongai), Carboniferous formations. In the upper part of the Red river valley rich deposits of coal have been found between Yenbai and Bai-Duong, in a considerable tract of Tertiary rock. Limestone occurs also in the valley of the Mekong, forming an extensive *massif* in the district of Lakhon and in the basins of the Nam-ka-dinh and Nam-hin-bun. These limestones appear to be Carboniferous. In the region south of Lakhon the rock is Triassic, and gold has been observed in several districts. The natives collect it in very small quantities by a washing process. In the lateral valleys of the Mekong copper and tin are found. On the course of the Nam-paton, a tributary of the Nam-hin-bun, the natives work a moderately productive tin-mine. Layers of spiegeleisen, limonite, and other iron ores are numerous in the Laos states, in which also antimony occurs.

Climate.—The climate of Indo-China is that of an inter-tropical country, damp and hot. But the difference between the southern and northern regions is marked, as regards both temperature and meteorology. Cochin-China and Cambodia have very regular seasons, corresponding with the monsoons. The north-easterly monsoon blows from about the 15th of October to the 15th of April, within a day or so. The temperature remains almost steady during this time, varying but slightly from 78·8° to 80·6° F. by day to 68° F. by night. This is the dry season. From the 15th of April to the 15th of October the monsoon reverses, and blows from the south-west. The season of daily rains and tornadoes commences. The temperature rises from 80·6° to 84·2° F., at which it remains day and night. April and May are the hottest months (from 86° F. to 93·2° F.). The damp unwholesome heat sometimes produces dysentery and cholera. The climate of Annam is less regular. The north-easterly monsoon, which is "the ocean-wind," brings the rains in September. The north-easterly gales lower the temperature to below 59° F. September is the month in which the typhoon blows. During the dry season—June, July, and August—the thermometer oscillates between 86° F. and 95° F. The nights, however, are comparatively cool. Tongking has a winter season—October to May. The temperature, lowered by fog and the rains, does not rise above 75·2° F. and descends to 50° F. over the delta, and to 44·6° F. and even 42·8° F. in the highlands, where white frost is occasionally seen. The summer, on the other hand, is scorching. The wind veers to the south-east and remains there until October. The temperature rises to 82·4° F. to 86° F.; often it reaches, and continues for several days at, 95° F., 100·4° F., and even 104° F. The nights are distressingly airless. The Laos country in the interior and lying at a high altitude is cooler and drier. Its deep valleys and high hills vary its climate. Observations made of late years show its salubrity, the temperature varying in summer between 68° F. and 77° F., in winter between 34·4° F. and 37·4° F.

Fauna and Flora.—In the populous cultivated districts wild animals, once plentiful, have retired towards the wooded districts. The wild life of Laos includes fairly numerous herds of elephants, the rhinoceros (one- and two-horned; rhinoceros horn, employed as a "medicine," fetches about 55 piastres, 132 francs, per kilogram), tiger, panther, brown bear, tree bear, monkeys and rats, among which are the musk rat, the palm rat, and the *nu-khi*, or rat found in the rice-fields of the highlands, in which its ravages are considerable. In mountain districts the leopard, wild boar, and deer are found, and in the neighbourhood of habitations the tiger-cat and ichneumon. The buffalo is commonly found wild in Laos; as a domesticated animal it also holds a prominent place. The zebu bull is used for transport purposes. Attempts to acclimatize the Arab horse and to introduce sheep from Aden and China have failed. There is, however, an indigenous race of horses, excellent in spite of their small size—the horses of Phu-Yen. Among birds the woodcock, peacock, and numerous species of duck inhabit the woods and marshes. The goose and guinea-fowl appear, as also the turkey, to have become easily acclimatized. Reptiles (apart from the caymans of the Mekong, which attain a length of over 30 feet, and are much appreciated by the Annamese as food) are extremely numerous and varied in species. The rivers are rich in fish. The sole is found in the rivers of Tongking. The Mekong is fished for two species peculiar to it—the *pa-beuk* and the *pa-leun*, which attain a length of nearly 6 feet, and upon which the fishermen pay a tax of one piastre per fish into the royal treasury. This tax brings in 1000 piastres annually. All varieties of mosquitoes, ants, and leeches combine to render the forests bordering the Mekong impracticable. Peculiar species of grubs and caterpillars destroy the cotton and coffee plantations of Cochin-China. The silkworm may be said to be indigenous to Tongking, where there are 7450 acres of mulberry trees. The flora is inter-tropical, and comprises nearly all the trees known in China and Japan. Formerly the teak was believed not to exist in the forests of Indo-China, but it was found some years ago in considerable abundance, and plantations of it have been made. Certain hard woods are used for marqueterie and other ornamental work. New products have been introduced. Cotton, previously cultivated in Cochin-China and Cambodia, gives excellent results in Laos. Tea, of which there are a certain number of plantations in the highlands of Tongking and Annam, grows wild in Upper Laos, and in quality closely resembles the Pou-eurl or Pueul variety so noted in Yunnan. Cocoa, coffee, and cotton have been cultivated in Tongking and Cambodia. Cinnamon and cardamoms are gathered in Laos and Annam. The area under rice has been much extended. All European fruits and vegetables have been introduced into Tongking, and with certain exceptions—the grape, for example—succeed perfectly. Measures taken to secure the monopoly of opium have notably increased the cultivation of the poppy.

Ethnology.—The Annamese and Cambodian populations have long been known, but since they have been brought into touch with civilization they have developed new characteristics. Since, owing to the restored tranquillity of his country, the fruit of his labour has been secured to him the Annamese has become more active and more industrious. As a soldier he has displayed the valuable qualities of endurance, intelligence, and discipline. The race is capable of development. Independent populations, isolated and even savage, the names of which

were hardly known, have been brought into contact with civilization. It has been recognized that the races familiarly known by a certain name have also various others. It is generally believed that the yellow people from China and the brown people of Aryan stock from India have driven back the older Malay races into the interior of the country. The Khmer of Cambodia probably belong to the Brahminical race; the sculptures of Angkor, in which are to be recognized the primitive Indian deities, give colour to this belief. Driven into the interior, the vanquished races have mixed and blended with the peoples whom they found there. New tribes have arisen, intermingled with fugitives from China, Annam, and even Siam. The Laos folk have for the most part come to predominate in this mixture. However this may be, the savage tribes (a term no longer exact) fall into two categories. In the north of Tongking people of Laos origin occur—the Thôs round Kaobang, the Muongs in the mountains bordering the Red river. When mixed with Chinese the Muongs and the Thôs are known as the Hung-dans, Mâns, and Miens. The Muongs are bigger and stronger than the Annamese, their eyes often almost straight. They have square foreheads, large faces, and prominent cheek-bones. In the centre and south of the Indo-Chinese mountain chain are found, under a multiplicity of names—Phon-tays, Souis, Bah-nan, Bolovans, Stiengs, Mors, Kongs, &c.—people of Malayan origin mixed with all the races of Indo-China. Laos is inhabited by an essentially miscellaneous population—Laotians, Khâs, Phais, Yuns, Lus, Phou-thais, Meos, Hos, and Yaos—of which the Laotians, numbering 67,000, and the Khâs, 63,000, form the bulk. Although Laotian legends assign to these a common origin, the difference of types, languages, and religions is at variance with this hypothesis. The Khâs appear to have preceded the Laotians in the country, though it is probable that the Laotians of Dien-bien-Phu have conquered and subjected the former. The Laotians may be of Mongol origin. The Yuns are Laotians settled on the right bank of the Mekong at Xieng-Mai, Xieng-Sen, and Muong-Nam, and are only distinguished from their congeners by the parts of the body on which they are tattooed. They tattoo the body instead of the thighs and legs as do the Laotians, whom for this reason they call "*Lao-phung-kao*," "the white-bodied Laotians," terming themselves "*Lao-phung-dam*," or "black-bodied Laotians." The Khâs, Meos, Yaos, and Hos are probably aborigines, and cultivate rice, poppy, and maize. The first-named, settled on the mid-course of the Mekong, between Lakhon and Stung-treng, were at a comparatively recent date veritable savages, reduced to the lowest degree of misery.[1] To-day they are on the road to civilization. They trade with Cochin-China and Cambodia, and at Stung-treng there is a post office and a steamer service.

Area and Population.—The extent of the area of French Indo-China is not exactly known. It is estimated approximately at 250,000 square miles.[2] No census has been taken of the population except in Cochin-China. It is estimated at 20,000,000, of whom 11,000,000 are in Tongking, 4,000,000 in Annam, 2,300,000 in Cochin-China, 1,500,000 in Cambodia, about 450,000 to 500,000 in the Laos states. The population of this latter country was estimated at first at only 160,000, but the verifications made since the French occupation have modified this figure. The province of Stung-treng alone, formerly believed to be almost uninhabited, contains 60,000 inhabitants.

Religions.—The Annamese religion is a somewhat vague and very tolerant Buddhism, which in practice resolves itself chiefly into the worship of ancestors. Certain ceremonies performed in Cambodia resemble distantly the Brahminical cult. The Catholic religion has been introduced by missionaries. The course of its history has not been free from catastrophes and accidents. There is an apostolical vicariate in Cochin-China, one in Cambodia, and several mission stations in Tongking. Two of these missions are mainly conducted by Spanish priests. Public instruction, means of communication, roads, railways, are "localized," and will be found separately treated in the articles upon Tongking, Cochin-China, and the Laos states.

Government and Finance.—Before taking its present form the governmental organization of Indo-China underwent many changes. Originally Cochin-China, the only French possession in the peninsula, was a colony directly administered, like other colonies, by the ministry of marine, and its earliest governors were admirals. Later, as further conquests were effected,[1] Tongking and Cambodia were subjected to the *régime* of a protectorate somewhat ill-defined, and placed under the authority of a resident-general. The seat of the resident-general of Tongking was at Hanoi; of Cambodia, at Pnom-penh. The government of the colonies having been transferred from the ministry of marine to the ministry of commerce (by the decrees of 14th March 1889, 17th January 1893, and the law of 20th March 1894, which constituted a special ministry of the colonies), the control of the residencies passed gradually into the hands of civil agents. Cochin-China, which already by the decree of 8th February 1880 had been endowed with a colonial council, had a municipality, a chamber of commerce, and even a deputy in the French Parliament. There had been thus since 1817 three distinct states, each with its own ruler and government. But by the decrees of 17th October and 3rd November 1887 the unity of Indo-China was determined. By decree of October the post of director of the interior of Cochin-China was done away with and replaced by that of lieutenant-governor. Cochin-China thus ceased to be under the direct administration of the ministry of the colonies, and was placed under the immediate authority of the governor-general. The functions and powers of this official were, however, but vaguely defined before the decree of 21st April 1891, which conferred on M. de Lanessan, appointed governor-general, the most extensive powers. The residents-general and the lieutenant-governor of Cochin-China, as well as the military authorities, were placed under him. But this change of policy, which put an end to the system of expeditions and minor military operations, and restricted the power of the residents whilst restoring to the mandarins a share of authority, was unwelcome to numerous interests, which, combining, secured the abrupt recall of M. de Lanessan on 29th December 1894. The decree of 21st April 1891 was not, however, revoked, but the powers it conferred were restricted. After the appointment of M. Doumer, successor to M. Rousseau, who died 10th December 1896, this decree was again put in force on the former scale, and in 1898 it was supplemented by the decrees of 3rd and 31st July, which definitely established the political and financial unity of Indo-China. The unification of the budget has specially contributed to that of the government. The financial scheme is based on the political. Just as a single central government directs the various local governments, so in addition to the general budget comprising

[1] *Le Laos et les populations sauvages de l'Indo-Chine.* Harmand. 1880.

[2] This is claiming a large portion of country actually in the hands of Siam and administered by Siam.—ED. *E. B.*

[1] See TONGKING and COCHIN-CHINA in the earlier volumes of the *Ency. Brit.* (ninth edition).

the revenue and expenditure of the supreme government there are several local budgets, including the revenue and expenditure incidental to the individual provinces.

The revenue of this budget is provided by customs and excise duties, indirect taxes and contributions levied all over the country, and the opium monopoly formerly conceded, as regards the kingdom of Annam, to a company whose concession was revoked on 1st July 1893. Opium is taxed in Tongking. In Annam it is still farmed. The remaining resources belong to the local budgets, and are supplemented, when inadequate, by grants from the general budget. Since 1894 another budget, or rather several other budgets, have been created in Tongking, namely, those of the provinces or municipalities. Since the decree of 12th March 1882, Cochin-China has had municipal budgets; Tongking since 1894.

The customs tariff for Indo-China was fixed as regards imports by the law of 11th January 1892 and the decree of 29th November 1892; for exports, by the decree of 29th December 1898. Special taxes have been sanctioned by various orders or decrees from 1898 to 1899, as follows: upon salt, 25 francs per ton; upon alcohol, 2·50 francs per litre of pure alcohol; upon tobacco and cigars, 1·50 franc per kilogram of cigars, 0·75 franc of cigarettes, and 15 francs upon the half-*picul* (30 kilograms) native grown or introduced tobacco in leaf.

The sums assigned directly to the kings of Annam and Cambodia are chargeable upon the general budget. In consequence of agreements with the court of Annam, the king—or rather the council of ministers—nominates and directly pays the native officials in Annam, as distinct from Tongking. Hence the financial credit assigned to the court of Hué reaches a sum of 928,000 piastres, 533,000 of which are assigned to the expenses of the court and *comat* (council of ministers), 369,000 to the salaries of officials, and 26,000 to "unforeseen outlay." The allowance made to the court of Pnom-penh is a purely personal one. The king's civil list amounts to 372,000 piastres, that of the secondary king—the *obbarach*—to 25,200 piastres. The princes, sons of the king, are apportioned 15,000 piastres, not an excessive sum, King Norodom having fourteen sons and twenty-two daughters. The princes, sons of the *obbarach*, receive together 3000 piastres. In both 1898 and 1899 there was a considerable surplus balance both on the general budget and on the local budgets.

The following were the estimates for 1901:—Revenue, 22,998,000 piastres; expenditure, 22,982,000; surplus, 16,000 piastres. The principal receipts were classified as follows:—

Customs	5,940,000	piastres.
Indirect taxes and excise	15,060,000	,,
Registration of lands and stamp duties	807,000	,,
Posts and telegraphs	382,000	,,
Forests	247,000	,,
Interest on capital	200,000	,,

Any available surplus was, by decree of 20th October 1900, to be applied to the formation of a general reserve fund. Each of the local budgets has its own reserve, and official statements show that these reserves will enable Indo-China to contribute the sum of 12 million francs—more than half—to the military expenses chargeable on the mother country, and to appropriate about 20 million francs to railway construction.

Administration.—The government in its present form was organized by the decrees of 17th October and 3rd to 12th November 1887, and by those of 21st April 1891 and 31st July 1898. Indo-China financially and politically unified is, as we have seen, placed under the authority of a governor-general, assisted by a superior council of Indo-China, which, reorganized by the decree of 8th August 1898, is composed as follows: president, the governor-general; the general commanding as head of the troops; the rear-admiral commanding the naval squadron of the Far East; the lieutenant-governor of Cochin-China; the resident superiors of Tongking, Annam, and Cambodia; a representative (appointed by the governor-general) of the government of Laos; the chief of the *contrôle financier;* the head of the judicial service of Indo-China; the superintendent of the customs and excise of Indo-China; the president of the colonial council of Indo-China; the presidents of the chambers of commerce of Saigon, Hanoi, and Haiphong; the presidents of the united chambers of commerce and agriculture of Annam and Cambodia; the presidents of chambers of agriculture; two influential natives, and the chief of the governor-general's cabinet. A "permanent commission" of the council has been formed. The superior council meets annually to receive the budget, which "must be accepted by the governor-general at a session of the superior council." It must also be consulted on the distribution of military credits, and on the credits to be devoted to public works.

The governor-general is also assisted by a "council of defence." The general services of the customs, justice, public works, agriculture, and commerce are placed directly in the hands of the governor-general. He presides over the council of ministers—*comat*—of Annam. The protected governments of Annam and Cambodia are under his control, and, in reality, under his command. He therefore exercises sovereign power throughout Indo-China. He is answerable to the minister of the colonies. There is a *contrôle financier* in Indo-China, dependent upon the ministry of the colonies. Its returns have to be communicated to the governor-general.

The town of Saigon (*q.v.*) is officially the capital of Indo-China. The superior council, however, does not necessarily sit at Saigon. It is annually convoked in the capital of one of the local governments, as Hanoi, Pnom-penh, and Hué.

Justice.—The whole of Indo-China is, in principle, subject to French justice, represented by a court of appeal and a certain number of tribunals. As recently as 1898 the administration of justice was not centralized. There was a court of appeal at Hanoi, and another at Saigon. But the decree of 8th August 1898 suppressed the court of appeal at Hanoi, which ranks now only as "the third chamber of the court of appeal of Saigon." Three mixed tribunals of commerce are established at Saigon, Hanoi, and Haiphong. There are courts of first instance at Saigon (not classified), My-tho, Viah-Long, Hanoi (1st class), Bentre, Chaudoc, Cam-tho, Via-vinh, Long-Trang, Long Xuyen, and Pnom-penh, and several justices of the peace, from whose judgments there is no appeal. In Cochin-China no trace of Annamese justice now remains. All the inhabitants, without distinction of race, are amenable to French tribunals. The decree of 7th March 1895, on "the organization of justice" in Cochin-China and Cambodia, contained an almost complete code of civil and criminal procedure. The decree of 8th August 1898 extended over the whole of Indo-China the jurisdiction of the court of appeal at Saigon. In Annam-Tongking, however, the natives are still subject to Annamese justice, represented in each province by a mandarin, called the *An Sat.* At the same time, whenever a Frenchman, or a naturalized Frenchman, is a party in an affair, French justice only is competent.

Public Works.—The order of 9th September 1898 placed the public works of Indo-China under the "direct authority of the governor-general as regards works entered to the general budget account." There is a director of public works in Indo-China at Saigon, a director of engineering in the other countries. In 1895 a "special service" was created in Tongking to consider railway business.

Posts and Telegraphs.—The postal service of Cochin-China was reorganized by a decree of 7th October 1881, that of Tongking by a decree of 20th September 1883. A general management created in 1887 was suppressed by an order of 10th January 1889. At present there is no general management. The post and telegraph offices in Indo-China number 223, of which 60 are in Cochin-

China, 105 in Tongking, 22 in Annam, 18 in Cambodia, and 18 in Laos.

The Army—Land Force.—The military services are under the authority of a general of division commanding in chief. There is a *Direction d'Artillerie* in Tongking, and another in Cochin-China. The troops form three brigades of three regiments with seven batteries. The four military districts of Tongking are commanded by superior officers. In 1898 four regiments of Tongkingese *tirailleurs* (sharp-shooters), one of Annamese, a company of Cambodian *tirailleurs*, and a squadron of Annamese *chasseurs* or light horse were raised, and a mobile reserve of about 7500 men constituted. The pay of sub-officers has been raised, and 178,000 piastres are spent on the *gendarmerie*.

Sea Force.—Indo-China is protected by the naval division of the Far East, to which is also attached a certain number of iron-clad gunboats.

Navigation.—The general movement of the ports of Indo-China is shown in the following table :—

Year.	Steamers.		Sailing Vessels and Junks.		Total.	
	Number.	Tons.	Number.	Tons.	Number.	Tons.
1885	766	775,745	120	15,494	886	791,239
1895	766	764,444	1525	72,624	2291	837,068

Taking the movement country by country, the shipping figures for 1898 were as follows :—

		Number.	Tonnage.
Annam. Entries	French vessels	12	27,950
	Foreign vessels	135	38,345
	Total	147	66,295
Tongking. Entries	French vessels	132	132,827
	Foreign vessels	915	195,640
	Total	1047	328,467
Cochin-China. Entries	French vessels	221	305,500
	Foreign vessels	377	425,868
	Total	598	731,368
	General total	1792	1,126,130
Annam. Departures	French vessels	16	30,597
	Foreign vessels	135	36,821
	Total	151	67,418
Tongking. Departures	French vessels	130	130,315
	Foreign vessels	752	186,040
	Total	882	316,355
Cochin-China. Departures	French vessels	223	305,500
	Foreign vessels	356	424,281
	Total	579	729,781
	General total	1612	1,113,554

In 1899 there entered the port of Saigon 237 French vessels of 333,714 tons, and 435 foreign vessels—for the most part British—of 477,443 tons. For Annam the figures were, 124 French vessels of 156,256 tons, and 375 foreign vessels of 73,890 tons, besides 7194 Annamite junks of 94,705 tons.

Commerce.—The commercial movement of Indo-China notably increased during the last ten years of the 19th century, as is apparent from the following figures :—In 1888 Indo-China, as a whole, imported to the value of 56,086,752 francs, exported to the value of 71,026,683 francs ; general commercial total, 127,113,435 francs.

In 1892 commercial statistics were tabulated for each of the three countries separately :—

	Imports (Francs).	Exports (Francs).	Total General Commerce (Francs).
Cochin-China and Cambodia	35,546,628	80,706,856	116,253,484
Annam	4,671,473	3,513,688	8,185,161
Tongking	28,432,772	10,851,026	39,283,798
Totals	68,650,873	95,071,570	163,722,443

In 1898 the imports (excluding specie) from France and French colonies amounted to 44,415,786 francs ; from other countries to 58,028,560 francs; total, 102,444,346 francs; the exports to France and French colonies amounted to 29,592,742 francs ; to other countries to 97,918,237 francs ; total, 127,510,979 francs.

The chief articles of import were colonial commodities for consumption, valued at 4,583,927 francs (France supplied the value of 3,176,713) ; farinaceous foodstuffs, 1,517,958 francs (Hong Kong 1,149,785) ; textile fabrics, 15,731,000 francs (France 6,545,865, England 3,329,574, Hong Kong 3,304,348, Singapore 2,446,765) ; and metal-work, 33,369,772 francs (France 19,483,370, England 1,520,622, China and Japan 11,029,058). Special mention should be made of "Siamese paddy," which is benefiting by the temporary duty-free admission. In 1898, from August to December (inclusive) 6,240,875 kilograms entered, and from September to December 4,303,249 kilograms (2,699,476 white rice, 1,603,773 rice cargo or partially husked rice). Rice and its derivatives, which in 1898 reached a value of 88,113,033 francs, ranked first among the exports. Fishery products figured at 6,487,841 francs, pepper at 4,418,028 francs, raw hides at 1,747,586 francs, cotton-in-pod—which finds a market in Japan—at 1,621,697 francs, raw silk at 1,332,037 francs.

In 1899 the value of the imports amounted to 115,424,500 francs, of which France contributed 30,880,000, and the exports to 140,137,240 francs, of which 46,071,000 went to France. In 1900 the imports reached a value of 186,044,000 francs, of which France contributed 74,226,000 francs, and the exports 151,338,000 francs, of which 33,052,000 went to France.

Mines and Metals.—Tongking, in its mountainous districts, is rich in metals. Considerable quantities of coal are mined at Hongai, on Allong Bay, in the island of Kebao, situated in the same bay, and at Nongson near Tourane. The output of Hongai coal amounted in 1899 to 210,446 tons. Coal concessions have been made in the coal regions of the Red river, at Thuyen-Khan, and in the neighbourhood of Yenbai. Zinc mines are also worked. Gold-washing on the rivers of Tongking is still carried on by Chinese. Concessions have been applied for in Laos for gold and tin mining. A tin mine of rather small yield worked by natives exists on the river Pa-ten.

Weights and Measures.—A recent decree has introduced the French system of weights and measures into Cochin-China, but in the other four countries the ancient weights and measures are still in use.

Money.—Native money consists of *sapeks*, *ligatures*, and *piastres* of variable currency. The piastre, which formerly was equivalent to 4·50 francs, has now fallen in value to 2·40 francs. The "question of the piastre," with its bearings on administration on one hand and commerce on the other, is one of the most complicated problems which could be presented to the Government.

History.—From 1884 onwards the history of Indo-China may be divided into two distinct periods, characteristic of the political conception and governmental system adopted by the French Government. In the first period, 1884–91, the French agents in Tongking and Indo-China generally proceeded (under cover of the protectorate established by the treaty of 5th June 1884 between France and Annam) with the definite conquest and annexation of Tongking and also Annam. Cochin-China itself openly designed to seize the southern provinces of Annam, upon the borders of which it lay. This policy, momentarily checked by the war with China, was vigorously, even violently, resumed after the treaty of Tientsin, 9th June 1885. The citadel of Hué was occupied on 5th July 1885 by General de Courcy. The Annamese Government forthwith decided upon rebellion. An improvised attack upon the French troops was led by the ministers Thu-yêt and Thu-ong. The revolt was promptly suppressed. The regent Thu-yêt and the king Ham-N'ghi —Prince Ung-lich, crowned 12th August 1884 under the title of Ham N'ghi—fled. The germ of this policy is to be found in the treaty of 5th June 1884, which gave France the protectorate over Annam. The French Government, following a very widespread error, regarded Tongking and Annam as two distinct countries, inhabited by populations hostile to each other, and considered the Tongkingese as the oppressed vassals of the Annamese conqueror. To conquer Annam, it was said, would liberate Tongking. This misconception produced the worst consequences. With the flight of the king civil war commenced in Annam. The people of Tongking, whose submission the court of Hué had not dared to demand,

began to rise. Taking advantage of this state of anarchy, pirates of the Black Flag, Chinese deserters, and Tongkingese rebels devastated the country. The occupation of Tongking became a prolonged warfare, in which 25,000 French, compelled to guard innumerable posts, had to oppose an intangible enemy, appearing by night, vanishing by day, and practising brigandage rather than war. The military expenditure, met neither by commerce, which had become impossible, nor taxation, which the Annamese could not pay nor the French receive, resulted in heavy deficits. Paul Bert, who hoped to gain the confidence of the mandarins by kindness and goodwill, did not succeed in preventing, or even moderating, the action of the military *régime*. Under his governorship there was much fighting. Thanquan, Hon-Koi, Laokai, Pak-Lun, and Cao-Bang were occupied, but the troops were driven back to the delta and almost invested in the towns. Disappointed in his hopes and worn out rather by anxiety than work, Paul Bert succumbed to his troubles on 11th November 1886. His successors possessed neither the strength nor the insight necessary to grapple with the situation. M. Constans, however, appointed "provisional" governor-general after the death of M. Filippini, succeeded to a certain extent in reviving commerce in the towns of the delta. But after him MM. Richaud, Bihourd, and Piquet were all equally powerless to deal with the uninterrupted "bush-fighting" and the augmentation of the deficit, for no sooner was the latter covered by grants from the mother country than it began to grow again. At the close of the financial year in 1890 France had paid 13,000,000 francs. In April 1891 the deficit again approached the sum of 12,000,000 francs. The rebels held almost all the delta provinces, their capitals excepted, and from Hanoi itself the governor-general could see the smoke of burning villages at the very gates of his capital.

At this point a complete change of policy took place. M. de Lanessan, a Paris deputy sent on a mission in the course of 1887, made himself acquainted with the government and the court of Hué. He recognized the absolute falsity of the story which represented the Tongkingese as the oppressed subjects of the Annamese. He demonstrated the consanguinity of the populations, and after intercourse with the regents, or ministers, of Hué he realized that the pacification of the country depended upon harmonious relations being established between the general government and the court. Appointed governor-general with the fullest powers on 21st April 1891, he presented himself at Hué, concluded with the *comat* an agreement based on the principle of a "loyal protectorate," and reassured the court, up to this point uneasy under menace of annexation. The *comat* shortly issued a proclamation under the great royal seal, never hitherto attached to any of the public acts imposed upon the king by the governors, who had been unaware of its existence. In this proclamation the king ordered all his subjects to obey the governor-general and to respect him, and commanded rebels to lay down arms. The effect was immediate—disorders in the delta ceased. The pirates alone, in revolt against the king of Annam and all authority, continued their brigandage. But the governor-general instituted four "military districts," the commanders of which were commissioned to destroy the pirates. At the same time he placed a force of native police, the *linh co*, at the disposal of the mandarins, hitherto regarded with suspicion and intentionally deprived of all means of action. Order was restored within the delta. In the mountainous districts infested by pirates roads were opened and posts established. The chief haunts of the pirates, among others those of Yen-Thé, were demolished, and during 1893 the foremost pirate chiefs gave in their submission. The Indo-Chinese budget regained its balance. On the Chinese frontier agreements were concluded with Marshal Sou, in command of the Chinese forces, regarding the simultaneous repression of piracy in both countries. But on the Mekong difficulties arose with the Siamese. For centuries Siam had occupied the valley of the Mekong, and her troops had crossed the river and occupied the left bank. Luang-Prabang was in the hands of the Siamese, who had also established posts at Stung-treng and elsewhere. Friction occurred between the French agents and Siamese soldiery. After the death of Inspector Grorguin on 5th June 1893 the French Government occupied Stung-treng and Khong. France demanded explanations and redress at Bangkok, but the court refusing concessions, an ultimatum was presented to the king by M. Pavie, French minister to Siam. The terms of the ultimatum not having been complied with within the given time, the French flotilla, consisting of the gunboats *L'Inconstant* and *La Comète*, crossed the bar of the Menam on 13th July 1893, forced the entrance of the channel, and anchored at Bangkok, before the French legation. A second ultimatum was then presented. It contained the following conditions:—First, the occupation of Chantabun by the French until the Siamese should have entirely evacuated the left bank of the Mekong; secondly, the Siamese to be interdicted from maintaining military forces at Battambang, Siem-Rap, and generally from establishing fortified positions within 15½ miles of the right bank of the Mekong; thirdly, Siam to be interdicted from having armed boats on the great lake Tonle-Sap. This agreement was executed immediately, the Laotians being eager parties to it. On 29th September 1893 the king of Luang-Prabang (the "*Chau Sakkarine Tap Ritti Tamrong*") made his submission to the French Government, and besought it to use its influence with the court of Siam for the return to their families of the sons of princes and mandarins then in schools at Bangkok. The Siamese evacuated the left bank of the Mekong, and France took possession of Laos, a treaty, on the basis of the ultimatum, being signed on 1st October 1893. The disputes to which this affair with Siam had given rise between France and Great Britain were amicably settled by an agreement concluded 15th January 1896. This "declaration," virtually ratifying the treaty concluded in 1893 between France and Siam, settled the limits of the zones of influence of the two contracting Powers in the north of the Mekong regions and on the frontiers of Siam and Burma. Great Britain resigned to France the regions of the Muong-Sing which she had previously occupied. The great part of Siam included in the Menam basin was declared neutral, as also the Me-Ing basin in the north, Meklong Petchaburi and Bang Pa Kong rivers in the south. The neutral zone 15½ miles wide on the right bank of the Mekong was formally recognized.

During this period considerable changes were taking place in Indo-China. Bitterly attacked by the military authorities, who were irritated at being subordinated to a civil governor, and by the *bureaux* of the central administration, which had been compelled by the decree of 1891 to yield certain of their powers to the governor-general, M. de Lanessan was abruptly recalled on 29th December 1894. On the arrival of his successor, M. Rousseau, and before he was able fully to acquaint himself with the condition of the country, military expeditions recommenced, and the deficit soon reappeared. Tranquillity, however, being restored, attention was given to public works. On 12th October 1895 M. Rousseau left to ask Parliament to vote a loan of 100,000,000 francs. On 10th February 1896 a law was passed authorizing a loan of 80,000,000

francs, and on 14th March 1896 an office for the financial control of the government-general of Indo-China was established. In the interval a French company had obtained from China a concession to prolong the railway from Langson to Langchou on a tributary of the Canton river. M. Rousseau, who died on 10th December 1896, was replaced by M. Doumer, previously minister of finance, under whose government was realized, as has been before stated, the union of Indo-China. A great programme of public works was drawn up, and on 20th December 1898 M. Doumer obtained from Parliament authorization to contract a loan of 200,000,000 francs. A railway line between Hué and Tourane is in course of construction. In virtue of the powers granted for this loan, two issues each of fifty millions were successively floated, and the proceeds appropriated to the construction of the following railway lines:—(1) Hanoi to Haiphong (98 miles); (2) Hanoi to Ninh-binh (73 miles); (3) Saigon to Tan-lin (82 miles); (4, 5, 6) lines from Tourane to Hué (65 miles), from Yen-bai to Lao-kai (94 miles), and from Ninh-binh to Vinh (85 miles); (7 and 8) lines from Tan-lin to Lang-bian and Khan-hoa (321 miles), and from Lao-kai to Yunnan-sen (302 miles). The whole of these lines will constitute, with the lines already constructed, a complete network, bringing Saigon and Hanoi into direct communication with the Chinese frontiers of Kwang-li and Yunnan. The line from Hanoi to Kwang-si, constructed with the eighty million loan, is in operation. Finally a line is projected from Hué *viâ* Ailao towards the Mekong as high as Savanna-kek.

AUTHORITIES. — Since 1885 numerous official or semi-official periodical publications have been established; the two chief are *Revue Indochinois* (Hanoi), and the *Bulletin économique de l'Indo-Chine* (Saigon). Amongst standard works on the country may be mentioned:—BAUINAIS and PAULIS. *L'Indo-Chine: la Cochinchine contemporaine*, 1885.—DUPUIS. *La Conquête du Tonkin.*—MAT-GIOÏ. *Le Tonkin actuel.*—LECLÈRE. *Recherches sur la législation du Cambodge*, 1895.—DE LANESSAN. *L'Indo-Chine: l'Expansion coloniale de la France.* Various.—*La Mission Pavie*, 1899.—AUBARET. *Le Code Annamite.*—LEMIRE. *L'Indo-Chine.*—BONHOURE. *L'Indo-Chine*, 1900.—Colonel FAMIN. *Au Tonkin.*—PICANON. *Le Laos Français*, 1901. (J. M. A. DE L.)

Indore, a native state of India, in the Central India agency, with a total area of 8402 square miles. The population in 1881 was 1,055,217, and in 1891 it was 1,094,150, giving an average density of 130 persons per square mile. In 1901 the population of the Indore agency, which is not co-extensive with the state of Indore, was returned at 333,044, showing a decrease of 11 per cent., due to famine. The gross revenue is estimated at Rs.70,00,000. The Maharaja, Shivaji Rao Holkar, G.C.S.I., has visited England. The soil in the valley of the Narbada produces fine crops of wheat and poppy, yielding the Malwa opium of commerce; but drought prevailed in portions of the state in 1897, and again in 1900. The metre gauge railway from Khandwa to Mhow and Indore city (86 miles), continued to Neemuch and Ajmere, was constructed in 1876 at the cost of the state. About Rs.12,00,000 are coined annually at the mint. The city of INDORE is situated 1786 feet above the sea, on the left bank of the river Katki, near its junction with the Khan. It has a railway station. The population in 1881 was 83,091, and in 1891 it was 92,329. These figures include the residency, which is under British administration. The chief educational institutions are the Daly College, for the sons of the chiefs of Central India; the Holkar and Canadian Mission colleges, both affiliated to the University of Calcutta; and four high schools. There are two hospitals, maintained at a cost of about Rs.1,00,000, and a gaol, with an average of 300 prisoners. The Maharaja maintains a cotton mill, established in 1872, with 468 looms and 26,296 spindles, employing 1000 hands. In 1897–98 the number of chests of opium exported through the Indore agency was 4898, paying a duty of Rs.27,52,350.

Indre, a department in the centre of France, watered by the Creuse, the Vienne, and the Indre.

Area, 2666 square miles. From 296,147 inhabitants in 1886 the population decreased to 286,961 in 1901. Births in 1899, 5834, of which 420 were illegitimate; deaths, 5261; marriages, 2226. The department in 1896 had 546 schools, with 39,000 pupils, and the illiterate formed 5 per cent. of the population. The area under cultivation amounted in 1896 to 1,532,108 acres, 1,057,628 acres being plough-land and 37,066 acres vineyards. The wheat produce in 1899 amounted to the value of £1,175,000; rye, £87,000; barley, £151,000; oats, £655,000; vines, £39,000; the natural pastures and grass lands, £583,000. Indre in 1899 owned 26,230 horses, 13,480 asses, 138,920 cattle, 527,200 sheep, 96,200 pigs, and 39,700 goats. The production of iron maintains a fairly important industry in metals. Wool-spinning and pottery are likewise developed. Distillation produced in 1899 72,000 gallons of alcohol. Châteauroux, the capital, in 1901 contained 24,522 inhabitants.

Indre-et-Loire, a department in the centre of France, watered by the two rivers naming it.

Area, 2377 square miles. The population decreased from 340,921 in 1886 to 334,073 in 1901. Births in 1899, 5913, 424 of them illegitimate; deaths, 6316; marriages, 2384. In 1896 there were 648 schools, with 41,000 pupils, and 3 per cent. of the population was illiterate. The area under cultivation in 1896 amounted to 1,364,070 acres; 830,300 acres plough-land and 143,326 acres vineyards. The land in wheat yielded in 1899 the value of £1,323,000; rye, £54,000; barley, £88,000; oats, £40,000; vines, £1,004,000. Beetroot, hemp, and apples also yield important returns. Mangold-wurzel produced (1899) the value of £83,000. The live stock included 45,450 horses, 129,700 cattle, 165,920 sheep, and 54,200 pigs. Though destitute of coal and iron, the department in 1896 produced 108 metric tons of steel. Silk tissues constitute a thriving industry, as do also rope and paper manufacture. In 1898 96,000 gallons of alcohol were manufactured, and in 1901 the yield of wine amounted to 35,313,000 gallons. Tours, the capital, had in 1901 a population of 64,448.

Indus.—A considerable accession of exact geographical knowledge has been gained of the upper reaches of the river Indus and its tributaries by means of those military and political movements which have been so constant on the northern frontiers of India of recent years. The sources of the Indus are to be traced to the glaciers of the great Kailas group of peaks in 32° 20′ N. and 81° E., which overlook the Manasarowar Lake and the sources of the Brahmaputra, the Sutlej, and the Gogra to the south-east. Three great affluents, flowing north-west, unite in about 80° E. to form the main stream, all of them, so far as we know at present, derived from the Kailas glaciers. Of these the northern tributary points the road from Ladak to the Jhalung goldfields, and the southern, or Gar, forms a link in the great Janglam—the Tibetan trade route—which connects Ladak with Lhasa and Lhasa with China. Gartok (about 50 miles from the source of this southern head of the Indus) is an important point on this trade route. At Leh, the Ladak capital, the river is already some 300 miles in length, having pursued an almost even north-westerly course throughout that distance except for a remarkable divergence to the south-west which carries it across, or through, the Ladak range to follow the same course on the southern side that had been maintained on the north. This very remarkable instance of transverse drainage across a main mountain axis occurs in 79° E., about 100 miles above Leh. For another 230 miles, in a north-westerly direction, the Indus pursues a comparatively gentle and placid course over its sandy bed between the giant chains of Ladak to the north and Zaskar (the main "snowy range" of the Himalaya) to the south, amidst an array of mountain scenery which for the majesty of sheer altitude is unmatched by any in the world. Then the river takes up the waters of the Shyok from the north (a tributary

nearly as great as itself), having already captured the Zaskar from the south, together with innumerable minor glacier-fed streams.

The Shyok Affluent.—The Shyok is an important feature in Trans-Himalayan hydrography. Rising near the southern foot of the well-known Karakoram pass on the high road between Ladak and Kashgar, it first drains the southern slopes of the Karakoram range, and then breaks across the axis of the Muztagh chain (of which the Karakoram is now recognized as a subsidiary extension northwards) ere bending north-westwards to run a parallel course to the Indus for 150 miles before its junction with that river. The combined streams still hold on their north-westerly trend for another 100 miles, deep hidden under the shadow of a vast array of snow-crowned summits, until they arrive within sight of the Rakapushi peak which pierces the north-western sky midway between Gilgit and Hunza. Here the great change of direction to the south-west occurs, which is thereafter maintained till the Indus reaches the ocean.

The Gilgit Affluent.—At this point it receives the Gilgit river from the north-west, having dropped from 15,000 to 4000 feet (at the junction of the rivers) after about 500 miles of mountain descent through the independent provinces of northern Kashmir. (See GILGIT.) A few miles below the junction it passes Bunji, and from that point to a point beyond Chilas (50 miles below Bunji) it runs within the sphere of British interests. Then once again it resumes its "independent" course through the wild mountains of Kohistan and Hazara, receiving tribute from both sides (the Bunar contribution being the most noteworthy) till it emerges into the plains of the Punjab below Darband, in 34° 10′ N. All this part of the river has been mapped in more or less detail of late years. The hidden strongholds of those Hindustani fanatics who had found a refuge on its banks since Mutiny days have been swept clean, and many ancient mysteries have been solved in the course of its surveying. Amongst other interesting relics of the past the great "rock" Aornos of Alexandrian fame has been finally identified with Mahaban, and even the names of some of the contiguous villages of Greek story have been found in faint survival.

Indus of the Plains.—From its entrance into the plains of India to its disappearance in the Indian seas, the Indus of to-day is the Indus of the 'fifties—only modified in some interesting particulars. It has been bridged at several important points. There are bridges even in its upper mountain courses. There is a wooden pier bridge at Leh of two spans, and there are native suspension bridges of cane or twig-made rope swaying uneasily across the stream at many points intervening between Leh and Bunji; but the first English-made iron suspension bridge is a little above Bunji, linking up the highroad between Kashmir and Gilgit. Next occurs the iron girder railway bridge at Attok, connecting Peshawar with Rawal Pindi, at which point the river narrows almost to a gorge, only 900 feet above sea-level. Twenty miles below Attok the river has carved out a central trough which is believed to be 180 feet deep. Forty miles below Attok a bridge of boats carries the traffic from the railway terminus at Kushalgarh to the road which leads westwards to Kohat. At Mari, beyond the series of gorges which continue from Kushalgarh to the borders of the Kohat district, at the northern railway terminus of the Sind–Sagar line, there is a boat-bridge leading to Kalabagh (the Salt City) and northwards to Kohat. There is a boat-bridge opposite Dera Ismail Khan to connect that place with the railway; but there is nothing new in these southern sections of the Indus valley railway system except the extraordinary development of cultivation in their immediate neighbourhood. The Lansdowne bridge at Sukkur, whose huge cantilevers stand up as a monument of British enterprise visible over the flat plains for many miles around, is one of the greatest triumphs of Indian bridge-making and the most important of Indus bridges. Kotri will inevitably be connected with Haidarabad in Sind, and the Indus ere long will become the best-bridged river in India. The intermittent navigation which was maintained by the survivals of the Indus flotilla as far north as Dera Ismail Khan long after the establishment of the railway system has ceased to exist with the natural dissolution of the fleet, and the high-sterned flat Indus boats once again have the channels and sandbanks of the river all to themselves.

Lower Indus and Delta.—Within the limits of Sind the vagaries of the Indus channels have necessitated a fresh survey of the entire riverain. The results, however, indicate not so much a marked departure in the general course of the river as a great variation in the channel beds within what may be termed its outside banks. Collaterally much new information has been attained about the ancient beds of the river, the sites of ancient cities, and the extraordinary developments of the Indus delta. The changing channels of the main stream since those prehistoric days when a branch of it found its way to the Rann of Kutch, through successive stages of its gradual shift westwards—a process of displacement which marked the disappearance of many populous places which were more or less dependent on the river for their water supply—to the last and greatest change of all, when the stream burst its way through the limestone ridges of Sukkur and assumed a course which has been fairly constant for 150 years, have all been traced out with systematic care by modern surveyors till the mediæval history of the great river has been fully gathered from the characters written on the delta surface. That such changes of river bed and channel should have occurred within a comparatively limited period of time is the less astonishing if we remember that the Indus, like many of the greatest rivers of the world, carries down sufficient detritus to raise its own bed above the general level of the surrounding plains in an appreciable and measurable degree. At the present time the bed of the Indus is stated to be 70 feet above the plains of the Sind frontier, some 50 miles to the west of it.

Statistics.—The total length of the Indus, measured directly, is about 1500 miles. With its many curves and windings it stretches to about 2000 miles, the area of its basin being computed at 372,000 square miles. Even at its lowest in winter it is 500 feet wide at Iskardo (near the Gilgit junction), and 9 or 10 feet deep. The temperature of the surface water during the cold weather in the plains is found to be 5° colder than that of the air (64° and 69° F.). At the beginning of the hot weather, when the river is bringing down snow water, the difference is 14° (87° and 101° June). At greater depths the difference is still greater. At Attok, where the river narrows between rocky banks, a height of 50 feet in the flood season above lowest level is common, with a velocity of 13 miles per hour. The record rise (since British occupation of the Punjab) is 80 feet. At its junction with the Panjnad (the combined rivers of the Punjab east of the Indus) the Panjnad is twice the width of the Indus, but its mean depth is less, and its velocity little more than one-third. The discharge of the Panjnad at low season is 69,000 cubic feet per second, that of the Indus 92,000. Below the junction the united discharge in flood season is 380,000 cubic feet, rising to 460,000 (the record in August). The Indus after receiving the other rivers carries down into Sind, in the high flood season, turbid water containing silt to the amount of $\frac{1}{229}$ part by weight, or $\frac{1}{410}$ by volume—equal to 6480 millions of cubic feet in the three months of flood. This is rather less than the Ganges carries. The silt is very fine sand and clay. Unusual floods, owing to landslips or other exceptional causes, are not infrequent. The most disastrous flood of this nature occurred in 1858. It was then that the river rose 80 feet at Attok. The

most striking result of the rise was the reversal of the current of the Kabul river, which flowed backwards at the rate of 10 miles per hour, flooding Naoshara and causing immense damage to property.

Industrial and Reformatory Schools.

—These two classes of institutions are frequently confounded in the public mind. In outward characteristics they are very similar; their system of management, their discipline, and the life led within their walls are alike. Nor is there much difference between the character of the inmates; the distinction is one not so much of criminality as of age. The senior schools or reformatories are schools to which are sent juveniles up to the age of 16 who have been convicted of an offence punishable with penal servitude or imprisonment; the junior or industrial schools, on the other hand, are designed, broadly speaking, for children up to the age of 14 who may not actually have committed an offence, but whose circumstances are such that if left in their surroundings they are likely to join the delinquent population. Thus the reformatories are for actual, the industrial schools for potential, delinquents, and the former contain juveniles some three years older on an average than the latter. The limit of detention in the former is the age of 19, and in the latter the age of 16. The two overlap to some extent, in that an actual delinquent, if under 12 and not previously convicted, may be committed to an industrial school.

Great Britain.

The origin and history of the two classes of schools are distinct. Reformatories derive from the voluntary institutions established by the Marine Society, founded in 1756, and the Philanthropic Society, founded in 1788, which occupied themselves in receiving and reforming the younger classes of criminals, particularly boys sentenced to transportation or long terms of imprisonment, and pardoned conditionally on their detention in such homes. In 1837 the Government itself made an effort to apply reformatory treatment to juveniles in Parkhurst Prison. Outdoor industrial employment was there combined with school instruction and religious teaching, with a view to the reformation of criminal boys; but the place remained technically a prison, and after a fluctuating career it was closed in 1864. The number of inmates had fallen from 536 in 1854 to 68 in 1864, no doubt owing to the passing in the interval of the first Reformatory Act. Thus reformatories have always had so much association with prisons that they have run parallel with them.

Origin of reformatories.

Industrial schools have never had any sort of association with prisons. They are the direct descendants of the "ragged schools," whose object was to provide education for destitute children, and so prevent them from falling into vagrancy and crime. The father of ragged schools was John Pounds, the Portsmouth shoemaker, who in the early years of the 19th century devoted himself to the improvement of the outcast children in his neighbourhood. By 1840 the ragged school movement had become an important one, and enlisted the powerful advocacy of such men as Lord Shaftesbury, Dr Guthrie, and Sheriff Watson of Aberdeen. There are industrial schools now in existence which actually occupy in part the primitive buildings in which they were housed as ragged schools.

Origin of industrial schools.

These preliminary remarks will render intelligible a brief history of legislation in regard to reformatory and industrial schools in Great Britain.

Before 1854 the only children legally detained in a reformatory were those sent there under conditional pardon (Parkhurst Prison Act, 1 and 2 Vict., c. 82, s. 11). The decade between 1840 and 1850 was marked by a powerful stirring of the public conscience with regard to the state of juvenile delinquency in the growing towns of the country, and a desire to check its growth by other than penal measures. Mr Monckton Milnes (afterwards Lord Houghton) introduced a Bill in 1846 for the establishment of reformatory schools. The Bill was rejected, but its introduction focussed the general interest, and in 1851 an important conference was held at Birmingham, the results of which were:—(1) The appointment of a committee by the House of Commons for the investigation of juvenile delinquency; (2) the introduction of a Bill by Mr Adderley (afterwards Lord Norton); (3) the establishment of reformatory schools in various districts by the independent efforts of individuals like Mr Adderley, Lord Leigh, Mr Barwick Baker, and Miss Mary Carpenter. A second conference was held at Birmingham in 1853, and resulted in the Government finally accepting Mr Adderley's Bill and carrying through in 1854 the first Reformatory Schools Act (17 and 18 Vict. c. 86). This Act was amended in 1855, 1856, and 1857. The Act of 1857 was important, in that it enabled for the first time local authorities, viz., Quarter-Sessions in counties and Councils of Quarter-Sessions in boroughs, to contribute towards the establishment of reformatories and the maintenance of children in them. Further, the power was given to grant licences to the inmates of reformatories. In the same year the Rev. Sydney Turner, who had been the superintendent of the Philanthropic Society's school, and was responsible for the establishment of the reformatory at Redhill on the lines of the agricultural colony of Mettray in France, was appointed her Majesty's inspector attached to the Home Office. In 1866 previous Acts were repealed, and the Consolidating and Amending Act now in force was passed. Amending Acts have been passed in 1872, 1874, 1891, 1893, and 1899, while by the Prison Act of 1877, which transferred local prisons to the state, the power of prison authorities to contribute to reformatories was expressly saved. The principal modifications which these amending Acts have effected are:—(1) The age up to which juvenile delinquents may be sent to industrial schools instead of to reformatories was raised to 12 (Acts of 1893, and Youthful Offenders Act, 1901); (2) imprisonment prior to committal to a reformatory school was abolished (Act of 1899); (3) the period of detention was to be not less than three nor more than five years—the offender in any case was not to be detained beyond 19 (Act of 1893); (4) extensive powers were given to managers to dispose of children without their parents' consent (Act of 1891).

Legislation as to reformatories.

The first Industrial Schools Act, introduced by Mr Dunlop, was passed in 1854, and applied to Scotland exclusively. It enabled a sheriff or magistrate to commit, up to 15, vagrant children, though not charged with any offence. Amending Acts were passed in 1855 and 1856, and in 1861 a consolidating statute was passed. The classes of children admissible were enlarged, so as to include not only mendicant and destitute children, but children under 12 charged with offences, and refractory children under 14. The powers of supervision, &c., which had by the original Act been given to the Committee of Council on Education, were transferred to the Home Secretary. The first English Act was passed in 1857. Amending Acts were passed in 1860 and in 1861. These early English Acts closely followed the lines of the Scottish ones, save as regards the admission of pauper children. In 1866 the English and Scottish Acts were consolidated by the

Legislation as to industrial schools.

principal Act now in force, the effect of which was, save again as regards pauper children, to place the industrial schools of both countries on the same footing. The local authority was to be the prison authority in England and the county board in Scotland, and the inspector of industrial schools and the inspector of reformatories were to be the same person, appointed by the Home Secretary. Amending Acts were passed in 1871 (the Prevention of Crimes Act), 1872, 1874, 1880, 1891, 1894, and in 1901 (the Youthful Offenders Act). The effect of these amending Acts has been in the main as follows:—(1) To increase the powers of local authorities to establish and maintain schools and contribute towards the establishment or maintenance of schools (Acts of 1872 and 1874); (2) to add to the classes of vagrant, mendicant, destitute, criminal, and refractory children already admissible to the schools (*a*) children under 14 of a woman twice convicted for crime, and (*b*) children under 14 found lodging in disorderly houses (Act of 1880); (3) greater powers were given to managers to dispose of children without their parents' consent (Act of 1891); (4) though children could not be detained in an industrial school after the age of 16, the period of supervision by the managers was extended to 18 (Act of 1894); (5) Courts of Assize were given the same powers as Courts of Summary Jurisdiction to commit children to industrial schools, and a previous conviction, resulting merely in a whipping or in the benefit of the First Offenders Act, was not to be a bar to the committal of a child under 12 to an industrial school (Youthful Offenders Act, 1901).

Elementary Education Acts.

But the effect of these amending Acts is small beside that of the parallel legislation affecting industrial schools to be found in the Elementary Education Acts. The English Elementary Education Act of 1870, providing for the establishment of school boards, gave them much the same powers in relation to industrial schools as had been in the hands of prison authorities. In 1871, by the Elementary Education (England) Act, school boards in England were enabled to establish and maintain industrial schools. The Elementary Education Act of 1876 carried the movement still further in England, making it obligatory on a school authority to take steps to send children to industrial schools who were liable to be sent, unless the school authority thought it inexpedient. Further, school authorities were required to apply to the justices for orders compelling the attendance at school of children over 5 and under 14 whose elementary education was habitually neglected, or who were found habitually wandering, &c. Justices were enabled, on the breach of such a school attendance order, to commit a child to a day industrial school, or, in default of that, to an ordinary industrial school; but a licence might be granted in Education Act cases after a lapse of one month instead of eighteen months, as in other cases. The effect of these provisions in the Education Acts has been a great increase in the number of children committed to the schools, and the establishment of two subsidiary classes of industrial schools—short detention or truant schools, and day industrial schools, in which children do not reside, but receive their meals, their elementary education, and a certain amount of industrial training. School boards in Scotland have been placed in almost precisely the same position as school boards in England by the Day Industrial Schools (Scotland) Act, 1893. Besides these public Acts, there are a few local Acts in force which should be mentioned—the Middlesex County Industrial Schools Acts, 1854 and 1875; the Glasgow Juvenile Delinquency Act, 1878; the Aberdeen Reformatory and Industrial Schools Act, 1885; the Reformatory and Industrial Schools (Manx Children) Act, 1884; the Reformatory and Industrial Schools (Channel Islands Children) Act, 1885.

Statistics.

At the close of 1900 there were in Great Britain 48 reformatory schools, 142 ordinary industrial schools, 15 truant schools, and 22 day industrial schools. Of the *schools for boys*, 26 reformatories and 48 industrial schools in England, with 4 reformatories and 13 industrial schools in Scotland, were under Protestant management; 4 reformatories and 13 industrial schools in England, with 1 reformatory and 3 industrial schools in Scotland, were under Roman Catholic management. Of the *schools for girls*, 7 reformatories and 32 industrial schools in England, with 2 reformatories and 12 industrial schools in Scotland, were under Protestant management; 2 reformatories and 12 industrial schools in England, with 1 reformatory and 3 industrial schools in Scotland, were under Roman Catholic management. In addition there were in England 3 and in Scotland 2 mixed schools with departments for both girls and boys; these were all under Protestant management. Of the boys' reformatories 2 were training-ships, and all but 3 or 4 of the remainder farm or country schools. Of the boys' industrial schools 8 were training-ships, and the remainder pretty equally divided between town and country schools. All the reformatories and the bulk of the industrial schools were managed by voluntary committees. Ten, however, of the latter (with all the truant and all save one of the day industrial schools) were managed by school boards, 8 by county councils, and 1 by the corporation of Birmingham. Affiliated with the industrial schools were 17 working boys' homes—a wholesome development of the licensing system which is likely to grow.

On the 31st December 1900 there were 4953 boys (England 4189, Scotland 764) and 658 girls (England 554, Scotland 104) *nominally* under sentence of detention in *reformatories*: 3786 Protestant, 1167 Roman Catholic boys; 498 Protestant, 160 Roman Catholic girls. But of these there were at large on licence 860 boys and 27 girls. On the same date there were under committment to *industrial schools* 14,384 boys (England 10,861, Scotland 3523) and 4719 girls (England 3302, Scotland 1417): 11,135 Protestant, 3249 Roman Catholic boys; 3042 Protestant, 1677 Roman Catholic girls. Of these there were at large on licence 1498 boys and 266 girls. Truants numbered 1332, with 4283 on licence, and children attending day industrial schools 3253, with 417 on licence.

If the figures for the period between 1876 and 1900 are studied, it will be seen that the number of juveniles sent to reformatories has positively diminished, while the number of those sent to industrial schools, after rapidly mounting up to 1893, has since that year remained practically stationary.

Finance.

The cost of the schools falls on the Treasury, local rates, and voluntary subscriptions. In addition, the schools to a certain extent earn, or save, money by the industries they practise. The Government grant is a weekly capitation fee; it varies from 6s. to 2s. a week. Reformatories and most of the training-ships get 6s. a week. In industrial schools the grant is varied in accordance with two considerations:—(1) Where a school was established prior to 1872, it gets for certain cases 5s. a week; later schools, 3s. 6d.; (2) whether the degree of criminality implied in the charge under which the child is committed is large or small, *e.g.*, for a child described as a thief the highest grant is given, for a child merely described as refractory 2s. is given. In all cases, however, both reformatory and industrial, the rates over 2s. are reduced after an individual has been for a certain time in the school. In the case of very young children nothing is paid by the Treasury up to six years of age, and the full grant only when the child attains ten years of age. In nearly all the English industrial schools the managers require the Government allowance to be made up to 7s. or 7s. 6d. a week by the local authority concerned. The total amount of the Treasury payments to reformatories in 1900 was, in England £62,053, Scotland £10,384. The contributions from county and borough rates were respectively £22,247 and £2652. Subscriptions, &c., came respectively to £1925 and £321. The profit on industrial departments was respectively £9384 and £1634. In the case of industrial schools during 1900 the Treasury grant was, for England £128,799, Scotland £54,413. Payments from the rates came respectively to £137,596 and £12,692; subscriptions to £15,819 and £9078; profits from industrial departments to £18,941 and £4935. It will be noticed that the share contributed by local authorities in Scotland is less than in England. As a matter of fact, there are several schools in Scotland which endeavour to struggle along on the Government grant, and receive practically no subvention from the rates. Speaking in round figures, it may be said that each inmate of a reformatory school costs £21 a year; of this £14 comes from the Exchequer, £5 from the rates, and £2 from voluntary subscriptions and payments made by the parents. Each

inmate of an industrial school costs £20 a year, of which £9, 10s. comes from the Exchequer, £9 from the rates, and £1, 10s. from subscriptions and parents' payments. In considering comparative tables from the years 1876, 1886, and 1896, it will be seen that while the share paid by the state has remained practically stationary, that of the rates has largely increased, and has to a considerable extent displaced voluntary subscriptions. The total cost per child has varied very little.

The death-rate for schools in Great Britain for 1900 was 4·47 per 1000.

Parental contributions. An important feature of the reformatory and industrial school system of Great Britain has been the recognition and enforcement of the duty of parents to contribute towards their children's maintenance. The contributions are collected by the inspector, and are paid in to the Exchequer in reduction of the Government grant. The work of gathering in this money presents serious difficulties, despite which, however, the amount realized is substantial. In the year 1900 it amounted to over £26,000. The Youthful Offenders Act, passed in 1901, places stringent powers in the hands of the department, and greatly simplifies the legal processes involved in the collection. It is fair to expect that in the future the amount collected will increase, and the moral effect on parents be correspondingly strengthened.

System at work in the schools. As has been explained above, the system at work in reformatory and industrial schools is very much the same. An effort is made to arouse in the schools something of the public school spirit, and as far as possible the size of the various institutions has been kept within reasonable limits. The ideal aimed at has been the avoidance of schools so big that the superintendent cannot know personally each of the children committed to his charge. Many successful boys' reformatories will be found with fewer than 100 inmates, and industrial schools with 150 or fewer inmates. The numbers in girls' schools are fewer, 50 in reformatories and from 60 to 80 in industrial schools being fair average numbers. Roman Catholic schools as a rule run to larger numbers than Protestant; this is probably due partly to the nature of their management, generally a religious community, and partly to motives of economy. Three girls' industrial schools and one boys' reformatory (Redhill) are on the system of a community of separate houses or cottages. One girls' industrial school (Maryhill, Glasgow) combines the advantages of the central home and the detached cottages.

The reformatory influences at work in both reformatory and industrial schools may be described under four heads:—

1. *Religious Instruction.*—In every school the superintendent is assisted by ministers of religion in the effort to inculcate the principles of religion and morality. Many of the Roman Catholic schools are actually under the management of religious communities. In accordance with the salutary tendency to allow children the utmost possible liberty, and to increase their opportunities of mixing with the outside world, it is considered more satisfactory, in Protestant schools at any rate, that children should attend divine service at outside churches than in a chapel of their own.

2. *Elementary Education.*—The scheme of elementary education is very much the same as obtains in the ordinary day-school. Most of the children only attend school half-time, but they attend regularly; and in a good industrial school it will be found that what a child loses in the schoolroom it more than gains in a workshop or needle-room, where educational methods are employed.

3. *Industrial Training.*—More variety in industrial training is to be found in boys' than in girls' schools. There are training-ships, with their nautical training; farm-schools, where agricultural work takes the principal place; town schools, where trades are practised; and suburban schools, where a training can be given in horticulture as well as in trades. In nearly all boys' schools great importance is attached to musical training, since an efficient school band affords an excellent means of disposing of boys in army bands. The industrial training in boys' schools is improving; the principles of technical education are better understood, and an attempt is made not only, by occupying children, to inculcate the habits of industry, but also, by explaining to them the theory of what they are practising, to develop the intelligence. The value, too, of drawing is now generally recognized. The main object in the case of girls is to prepare them for domestic service. Here also an effort is made to perfect their industrial training. In many schools not only do the girls assist in the school kitchen, needle-room, laundry, &c., but the older ones also attend definite courses of lessons in cookery, laundry work, cutting-out and dressmaking. Although the great majority of girls enter domestic service, a few are singled out for training as teachers, dressmakers, shop assistants, or other occupations for which they show a special aptitude.

4. *Physical Culture.*—Physical culture receives marked consideration, for it is recognized as a duty to do the utmost by a sound athletic and gymnastic training to repair the ill effects of early neglect. The report of the Anthropometric Committee of 1883 brought to light the fact that the children entering industrial schools are physically the lowest class of the population, and though statistics published in H.M. inspector's report for 1900 show an improvement, the relative position remains the same. Nevertheless, small though the boys are, they are good material to work upon, for in many cases it is the excess of qualities like enterprise and courage which has got them into trouble. The physical training of girls is largely designed to improve their figures and gait; the utter neglect from which many have suffered in early childhood renders the task a difficult one, but the results to be achieved by patient work in a girls' school are just as encouraging as in a boys'. Mention may be made of various athletic leagues, which introduce a healthy spirit of competition, and remove the feeling of isolation, and of the open-air camp life indulged in by many schools, girls' as well as boys', during the summer.

An important auxiliary in the maintenance of discipline in general use is a mark system, to which various rewards are attached. The object of these mark systems is to reduce punishment to a minimum, and to form character as much by encouraging industry and good conduct as by punishing idleness and misbehaviour.

Disposal of children, and results of the system. The managers of schools are placed by the law in *loco parentis*, but it is often a hard struggle to prevent the natural, however undesirable, parents from again getting hold of their children when they reach a wage-earning age. For three years after children have left a school the managers have to keep an eye on them, and to report to H.M. inspector their addresses, occupations, and characters. The report of H.M. inspector for 1900 describes the position at the end of that year of the children who left the schools in the years 1897, 1898, and 1899. The total number of boys was 13,390, of whom 1939 were in the army, 443 in the navy, 1204 in the mercantile marine or fishermen, 1028 in farm service, 678 in factories, 487 miners, 475 carters, 395 iron and steel workers. Other occupations, in which fewer were engaged, need not be specified, but the number described as in merely casual employment was 577, of re-convictions 970, or 7 per cent., and of those lost sight of 727, or 5 per cent. The total number of girls was 3005: of these more than half entered domestic service, 381, or 38 per cent., in households where more than one servant was kept; laundry-maids numbered 244. The number in casual employment was 202, of re-convictions 62, or 2½

per cent., and of those lost sight of 141, or nearly 6 per cent. It is when the difficult work of *disposal* is under review that the Rev. Sydney Turner's contention in favour of the voluntary management of schools carries conviction.

A discussion of the effect of the schools on crime would require a treatise in itself. We may be content here to quote the guarded judgment of the editors of the judicial statistics during recent years. They are clearly of opinion that crime in England has diminished, and the editor for 1899, reviewing the period 1893–99, says: "I am inclined to think that the tendency towards a decrease in crime generally during the period extends to juvenile crime as a whole, and that at all events there is no ground for believing that there has been any large increase." Of the credit for this happy state of things a fair share may reasonably be claimed by the reformatory and industrial schools.

The Irish reformatory and industrial schools are, so far as regards the central authority, under the Irish Government, and the headquarters of the inspector, appointed by the Lord-Lieutenant, are at Dublin Castle. A Reformatory Schools (Ireland) Act was passed in 1858, and amended by Acts of 1868, 1881, 1893, and 1899. The Irish Industrial Schools Act was passed in 1868, and amended by Acts of 1871 (Prevention of Crimes Act), 1880, and 1901 (Youthful Offenders Act). Though there are minor differences, the law in Great Britain and Ireland is very similar, but the practice appears to have differed considerably. The royal commission of 1884 reported that, owing perhaps to the facts that there were in Ireland no school boards or board schools, no compulsory education, no district workhouse schools—no refuge, in fact, for children of the destitute and deserted class save the ordinary workhouse schools and the industrial schools, the latter were regarded as institutions for poor and deserted children, rather than for those of a semi-criminal class. The commissioners had no doubt that many children were sent to industrial schools in Ireland who could not be so sent in England, while they apprehended that numbers who were proper subjects for these institutions were left on the streets as waifs and strays. Efforts have been made by the Irish Government, particularly by a circular issued in 1898, to redress the balance. The royal commission of 1884 called attention to the number of children committed for "begging," and stated that there was reason to believe that children were often sent out to beg in order to qualify for admission to schools. But in H.M. inspector's report for 1900 it will be found that the number committed for "begging" had dropped from 1204 in 1894 to 676 in 1898, and 160 in 1900.

Ireland.

At the close of 1900 there were in Ireland 6 reformatory and 70 industrial schools, the immense majority of them being under Roman Catholic management. On 31st December 1900 there were 559 boys and 65 girls nominally under sentence of detention in a reformatory, but of these there were at large on licence 26 boys. On the same date there were 3672 (535 Protestants) boys and 4549 (401 Protestants) girls under commitment to industrial schools, but of these there were at large on licence 235 boys and 189 girls. An outstanding feature of these figures, as compared with those for England, is the high proportion of girls; the absolute number is nearly as high as that for the whole of Great Britain, viz., 4719. On the whole, numbers in Irish schools show a tendency of late years to decrease. Finance is regulated very much as in Great Britain, but the capitation grant is not reduced as it is there after a certain period. Per contra, Ireland lacks some of the minor advantages (*e.g.*, licence grants in reformatory cases) enjoyed in Great Britain. The Treasury contributed in 1900 to Irish reformatories £8915; rates, £4198; other sources, £349; and profits were estimated at £1055. To industrial schools in 1900 the Treasury contributed £97,853; rates, £41,944; other sources, £8779; while profits were estimated at £10,546.

Statistics.

The death-rate in Irish industrial schools in 1900 was 8·39 per 1000. The system at work in the Irish schools is, with natural modifications, much the same as that which obtains in Great Britain.

[See the reports of the House of Commons Committee of 1853, of the Royal Commission of 1884, of the Departmental Committee of 1895, and the annual reports of H.M. Inspectors for Great Britain and Ireland.]

Though the idea of the reformatory school was indigenous in England, its realization owed much to foreign precept and example. The provision of the French Penal Code, by which offenders under 16 are held to have acted *sans discernement*, was prominent in the minds of those who fought from 1840 to 1850 for the passing of a Reformatory Schools Act. The leading reformatory in Great Britain to-day is the Philanthropic Society's farm-school at Redhill, which was avowedly modelled on the famous agricultural colony at Mettray, near Tours, founded by M. Demetz in 1839. Both at Redhill and Mettray the colony is divided into separate houses, each containing from forty to sixty inmates, and supervised, as in the case of an English public school, by a house-master; but the colony at Redhill is smaller, the arrangement of the houses is on a less formal plan, and the display of "uniform" among the officers is reduced to a minimum. Another foreign school which largely influenced public opinion in Great Britain, as in Germany, was the Rauhe Haus, near Hamburg, founded by Dr Wickern in 1833. This began with a single cottage, but had grown in twenty years to a hamlet of twenty houses, with from twelve to sixteen inmates in each. The establishment was a Lutheran one; both boys and girls were admitted, though to separate houses, and a marked feature of the place was the number of "brothers," young men of good character qualifying for rescue-work as superintendents of homes, prison officers, and schoolmasters, who took part in the work, and swelled to an unusual extent the proportion of officials to inmates. The character and aims of the Rauhe Haus seem to have changed somewhat in modern days.

Reformatories abroad.

There are schools or "colonies" analogous to reformatory and industrial schools in most European countries —France, Germany, Austria, Belgium, Sweden, Norway, Switzerland (where the influence of Pestalozzi is discernible), and Italy. In all the principle of voluntary management is admitted, but in France, Germany, Austria, Belgium, and Italy there are schools directly managed by the Government or State. It may be fairly claimed for the system and the schools of Great Britain, as compared with those of the Continent, that the system attempts more jealously to enforce the principle of parental responsibility, and that the schools have as a general rule two signal advantages: (1) they are less formal and institutional; (2) far more use is made of the healthy discipline of games and field-sports.

In the United States, as on the continent of Europe, schools corresponding to reformatory and industrial schools are to be found, the oldest, the New York House of Refuge, dating from 1824. But the unique interest of the United States is connected with the *adult* reformatories, the best known of which are the establishments at Elmira in New York and Concord in Massachusetts (see Prison Discipline). The character and the scale of these may in a measure be judged by the following particulars:—

United States adult reformatories.

The reformatory, the buildings of which are on an ambitious scale and ornamental in style, was opened in 1876 for the reception of youthful male felons who are committed there for the statutory term for their particular offence to undergo a process of training and reformation in place of the ordinary punishment.

The total number received during the seventeen years was 6551; the age of the inmates varied from 16 years to 30 years, the average age being 21 years. The average number in confinement during 1893 was 1470. There were 1378 inmates at the close of the year, with an average period of detention of seventeen months. The total cost of maintenance for 1893 was \$215,223. The trade earnings amounted to \$53,458, leaving a net cost of \$161,765.

The reformatory is provided with 1258 cells, so that about 400 were necessarily associated two in one room. To avoid still more

overcrowding it had been found necessary to transfer 150 of the least promising inmates to the state prisons. This course had been found to act as an incentive to troublesome conduct on the part of inmates in order to secure their transfer to the prison, where an abatement of their sentence might be earned with less exertion on their part.

The prisoners committed to the reformatory are felons; 45 per cent. of them had previously been in contact with the restraining agencies of the law; 68 per cent. were illiterate; 75 per cent. were without regular occupation; 92 per cent. were without the benefits of good home surroundings. The object of the reformatory is, as far as practicable, to place the prisoner in "conditions parallel with those of free life," there to work out his institutional career.

The moral inducements of reformation consist of (1) division into grades, with differing degrees of comfort and social standing; (2) a wage-earning mark system; (3) the personal influence of the reformatory staff. Between 70 and 80 per cent. are said to respond to the efforts made for their good. For the remainder compulsion is found necessary, either by means of forfeiture of marks, degradation of rank, or personal chastisement. Thirty-four different trades had been taught during the year, and it is claimed that 78 per cent. of the discharged inmates went straight to the trade learned in the reformatory. Two evenings a week are devoted to education, and twenty of the best educated amongst the inmates assist in this work. Lectures and concerts are given periodically. There is a gymnasium, and 1175 of the able-bodied inmates are formed into a regiment to go through a course of military drill and training. Prisoners can, at the discretion of the managers, be released on parole, to be brought back again if found to be drifting into crime, but the release is made absolute after six months' satisfactory trial. The total number "paroled" during the seventeen years was 3723. Of these 259 were brought back, 110 were paroled a second time, and 10 a third time. It is claimed that probably about 80 per cent. of the prisoners are reformed, that is, "the discharged inmate returns to society not more, but probably less, likely to fall into crime than the virtuous of the class to which he belongs."

Elmira and the kindred institutions of the United States have been keenly discussed of recent years among European penologists. The success of the system for adults has not been universally admitted, and its adaptability to the conditions of the more thickly populated countries of the Old World has been questioned. Critics have further been alarmed by the costliness of the system. An English account of these American adult reformatories, with observations upon them, will be found in a Report to the Home Secretary, published in 1897 by Mr Ruggles-Brise, C.B., chairman of the Prison Commissioners. (J. G. L.)

Ineboli, a town, with an open roadstead, on the north coast of Asia Minor. It is the port of Kastamúni, with which it is connected by a carriage road, and exports wool and mohair. The exports and imports are valued at £445,000 annually. The population is 9000 (Moslems 7000, Christians 2000). There are British and other consular officers.

Inebriety, Law of.—The legal relations to which drunkenness gives rise are partly civil and partly criminal. The law as to the civil capacity of the drunkard is practically identical with the law as to the civil capacity of a person suffering from mental disease (see INSANITY, LAW OF). He can enter into a valid marriage or make a valid will, or bind himself by a contract, if he is sober enough to know what he is doing, and no improper advantage of his condition is taken. The Sale of Goods Act, 1893, also provides that where necessaries are sold and delivered to a person who by reason of drunkenness is incompetent to contract, he must pay a reasonable price for them; and "necessaries" for the purposes of this provision mean goods suitable to the condition in life of such person and to his actual requirements at the time of the sale and delivery.

Drunkenness comes under the cognizance of the criminal law as a form of breach of the peace. The Licensing Acts and other statutes of a similar character also create various offences in connexion with the sale of intoxicating liquors. Neither of these subjects needs to be touched upon here. The law as to the criminal responsibility of drunkards must, however, be examined.

Drunkenness, unlike insanity, was at one time regarded as in no way an excuse for crime. According to Coke, a drunkard, although he suffers from acquired insanity, *dementia affectata*, is *voluntarius dœmon*, and therefore has no privilege in consequence of his state; "but what hurt or ill soever he doth, his drunkenness doth aggravate it." Sir Matthew Hale took a more moderate view, viz., that a person under the influence of this voluntarily contracted madness "shall have the same judgment as if he were in his right senses"; and admitted the existence of two "allays" or qualifying circumstances: (1) *temporary* frenzy induced by the unskilfulness of physicians or by drugging; and (2) *habitual* or fixed frenzy. Those early authorities have, however, undergone considerable development and modification in later years. It is settled law that where a particular intent is one of the constituent elements of an offence, the fact that a prisoner was intoxicated at the time of its commission is relevant evidence to show that he had not the capacity to form that intent. Drunkenness is also a circumstance of which a jury may take account in considering whether an act was premeditated, or whether a prisoner acted in self-defence or under provocation, when the question is whether the danger apprehended or the provocation was sufficient to justify his conduct or to alter its legal character. Moreover, *delirium tremens*, if it produce such a degree of madness as to render a person incapable of distinguishing right from wrong, relieves him from criminal responsibility for any act committed by him while under its influence; and in one case at *nisi prius* (*Reg.* v. *Baines*, *The Times*, 25th Jan. 1886) this doctrine was extended by Mr Justice Day to temporary derangement occasioned by drink. The law of Scotland accepts, if it does not indeed go somewhat beyond, the later developments of that of England in regard to criminal responsibility in drunkenness. Indian law on the point is similar to the English. In the United States the same liberal view is the prevalent legal doctrine.

Provision is made for the care of habitual drunkards by the Inebriates Acts of 1879, 1888, 1898, and 1899. Only an outline of the provisions of these statutes can here be attempted. They deal in the first place with non-criminal, and in the second place with criminal, habitual drunkards.

For the purposes of the Acts the term "habitual drunkard" means "a person who, not being amenable to any jurisdiction in lunacy, is notwithstanding, by reason of habitual intemperate drinking of intoxicating liquor, at times dangerous to himself or herself, or incapable of managing himself or herself and his or her affairs." A person would become amenable to the lunacy jurisdiction not only where habitual drunkenness made him a "lunatic" in the legal sense of the term, but where it created such a state of disease and consequential "mental infirmity" as to bring his case within section 116 of the Lunacy Act, 1890, the effect of which is explained in the article INSANITY, LAW OF. Any "habitual drunkard" within the above definition may obtain admission to a "licensed retreat" on a written application to the licensee, stating the time (the maximum period is two years) that he undertakes to remain in the retreat. The application must be accompanied by the statutory declaration of two persons that the applicant is a habitual drunkard, and its signature must be attested by a justice of the peace who has satisfied himself as to the fact, and who is required to state in part of the attestation that the applicant understood the nature and effect of his application. Licences (each of which is subject to a duty and is impressed with a stamp of £5, and 10s. for every patient above ten in number) are granted for retreats by the borough council and the town clerk in boroughs, and elsewhere by the County Council and the clerk of the County Council. The maximum period for which a licence

may be granted is two years, but licences may be renewed by the licensing authority on payment of a stamp duty of the same amount as on the original grant. When a habitual drunkard has once been committed to a retreat, he must remain in the retreat for the time that he has himself fixed in his application, subject to certain statutory provisions similar to those prescribed by the Lunacy Acts for asylums as to leave of absence and discharge; and he may be retaken and brought back to the retreat under a justice's warrant. The term of detention may be extended on its expiry, or an inebriate may be readmitted, on a fresh application, without any statutory declaration, and without the attesting justice being required to satisfy himself that the applicant is a habitual drunkard. Licensed retreats are subject to inspection by an inspector of retreats appointed by the Home Secretary, to whom he makes an annual report. The Home Secretary is empowered to make rules and regulations for the management of retreats, and "regulations and orders," not inconsistent with such rules, are to be prepared by the licensee within a month after the granting of his licence, and submitted to the inspector for approval. The rules now in force were made on 10th August 1888. There are also statutory provisions, similar to those of the Lunacy Acts, as to offences—(i.) by licensees failing to comply with the requirements of the Acts; (ii.) by persons ill-treating patients, or helping them to escape, or unlawfully supplying them with intoxicating liquor; (iii.) by patients refusing to comply with the rules. The Home Secretary may (i.) authorize the establishment of "State Inebriate Reformatories," to be paid for out of moneys provided by Parliament; and (ii.) sanction "Certified Inebriates' Reformatories" on the application of any borough or County Council, or any person whatever, if satisfied concerning the reformatory and the persons proposing to maintain it. An inspector of certified inebriate reformatories has been appointed.

Any person convicted on indictment of an offence punishable with imprisonment or penal servitude (*i.e.*, of any non-capital felony and of most misdemeanours), if the court is satisfied from the evidence that the offence was committed under the influence of drink, or that drink was a contributing cause of the offence, may, if he admits that he is, or is found by the jury to be, a habitual drunkard, in addition to or in substitution for any other sentence, be ordered to be detained in a state or certified inebriate reformatory, the managers of which are willing to receive him. Again, any habitual drunkard who is found drunk in any public place, or who commits any other of a series of similar offences under various statutes, after having within twelve months been convicted at least three times of a similar offence, may, on conviction on indictment, or if he consent, on summary conviction, be sent for detention in any certified inebriate reformatory. The expenses of prosecuting habitual drunkards under the above provisions are payable out of the local rates upon an order to that effect by the judge of assize or chairman of quarter-sessions if the prosecution be on indictment, or by a court of summary jurisdiction if the offence is dealt with summarily. The Inebriates Acts apply to Scotland and Ireland with adaptations.

Paper No. 242 of 1872; 1893 C. 7008.—*The Annual Reports of the Inspector of Licensed Retreats.*—WYATT PAINE. *Inebriates Acts*, 1879–1898. London, 1899.—BLACKWELL. *Inebriates Acts*, 1879–1898. London, 1899.—WOOD RENTON. *Lunacy.* London and Edinburgh, 1896.—KERR. *Inebriety*, 3rd edition, London, 1894, in which an excellent account of the systems in force in other countries for the treatment of inebriates will be found.

Infantry.—This term, adopted into the English language from either Italian or French, implies men equipped and armed for fighting on foot. The Italian *fante*, Boccaccio's *fanteria*, the French *fantassin* and *infanterie*, are portions of the same stock, offshoots from the Latin *infans*, employed in the sense of "youth." During the days of chivalry, youths of good family, dependants, and servants all marched as infantry in rear of the knights. The development of infantry soldiers during the long period between the mythical dawn of history and the present time is a continuous narrative of war following war, with scant intervals of peace. Infantry formed the bulk of all early armies from the date of David's capture of Jerusalem or the uncertain date of the siege of Troy, through the eras of the Greek and Macedonian phalanx and of the Roman Legion. Franks from Germany marched and fought on foot during and after the conquest of Gaul; Charlemagne in the 8th century employed masses of infantry to keep order in a kingdom extending from the Elbe to the Ebro, from the Atlantic to the mountains of Bohemia, and diagonally from the British Channel to Naples. The institution of chivalry did little to diminish the numerical preponderance of foot-soldiers over the rest of the forces; but growing skill in metal-working, and its special application to arms and armour, increased the relative power of mounted men, for they alone could bear the weight of complete defence. The cost of armour was great, and on the continent of Europe the infantry service was relegated to slaves and to freed serfs, whilst in England, from the Conquest onwards, yeomen and dependants of the feudal tenants formed a numerous but ill-armed and unorganized mass of infantry. On the borderland of the 12th and 13th centuries, infantry militia was the principal force employed by Philip Augustus in his contests against the English king and the Flemish soldiers of the Emperor Otho IV. In the 14th century cavalry of the highest quality dismounted and fought on foot both at Creçy and Poictiers, and at Agincourt the English archers played havoc with the cavaliers of France. A century later Spanish infantry rose to formidable prominence synchronously with the introduction of muskets and standing armies. In 1494 Charles VIII. embarked on his Italian campaign at the head of an army consisting of 3600 men-at-arms, 20,000 native infantry, 8000 Swiss mercenaries, a considerable body of infantry raised in Germany and called Lansquenets (Landsknecht), together with a formidable train of artillery; and with these he fought his way to Naples and back, although the bulk of the native infantry were the refuse of society—"branded and ear-cropped" for various crimes. The well-organized and, for the period, well-armed Swiss infantry withstood the shock of the best cavalry furnished by the Pope, the Emperor Ferdinand of Spain, and the republic of Venice. The Swiss, during their long defence against the House of Austria, compelled by poverty to depend exclusively on infantry, had gained confidence in resisting cavalry, and European powers employed them as mercenaries; but being as exacting as Prætorian guards, and therefore dangerous to their employers, they were gradually discarded, and armies were raised from native races. In modern times, as of old, infantry form the main body of all armies in the field; they are self-containing to a greater extent than either cavalry or artillery, and although limited as to speed of movement, they are less hampered by accidents of the ground than either of the other arms, and less dependent on daylight for effective action. They have a special value to Great Britain, in that their sea transportation is a comparatively easy matter.

The proportion of infantry to cavalry in most modern armies is approximately 6 to 1, with perhaps 3 artillery guns to each 1000 men of the other two arms combined;

but this ratio is varied in practice according to the climate to be encountered and the nature of the field of campaign. A proportion of cavalry and artillery which would be suitable to action in the plains of India would ill befit operations on the Himalayan spurs, or in the tropical forests of West Africa.

A branch of infantry service has grown into prominence during Great Britain's unceasing small wars. Mounted infantry are foot-soldiers who ride for purposes of accelerated locomotion; their action in the field differs from that of cavalry, whose normal fighting formation and equipment are planned for mounted men, whereas the rifle and bayonet of the infantry soldier preclude him from mounted combat.

The varying formation adopted by commanders of infantry during successive centuries is in the strictest sense a question of tactics, but the quality of the infantry in courage, discipline, and armament has largely affected the subject. Up to the time of Epaminondas, in the 4th century B.C., contending forces faced one another along their whole front of battle, but he introduced what is now called an echelon formation: his infantry of the highest quality were placed in a massive column on one flank or other, and the less good, indifferently armed, lighter troops were kept diagonally "refused"; thus the advanced flank of the line gave the heavy blow, which was supported by the refused echelon gradually coming into contact with the enemy. The Macedonian phalanx of the next generation, under the consummate leadership of Philip, overthrew the Peloponnesian armies; and that massive formation with flanking cavalry held good till the development of the more mobile Roman legions. Similarly at a later date the stately and successful flanking movements of the Prussian king, when continued by unappreciative successors, yielded to the new-born reckless mobility of the French under Napoleon; but the latter, during his prolonged wars, was driven to adopt more massive formations, as the battle losses of successive years weakened the fighting qualities of his armies. Nemesis, however, was unrelenting, for the fire efficiency of thin lines, with ample working space for individual soldiers, destroyed for all time the validity of dense columns.

The armament of infantry has varied with the years; from short swords and slings, to javelins, bows, and spears; thence to pikes and matchlocks, to flint muskets with bayonets in the muzzles, percussion guns with bayonets outside, muzzle-loading rifles, breech-loading rifles, to the magazine rifles and smokeless powder of the present day. Defensive armour has gradually been abandoned under the stress of desired mobility, and during each succeeding war period the weight of accoutrements carried by a foot-soldier is reduced more and more to the barest necessity—the extreme weight under which he can march and work being made up by ammunition in ever-increasing quantity as the improved mechanism of his arm demands a more lavish supply.

The numbers of infantry in Europe are enormous on paper, and in some of the well-governed states the actual and the paper numbers approximate to one another. By the army returns of the latest dates Europe retains $2\frac{3}{4}$ millions of infantry on a peace establishment; this number might be increased to $15\frac{1}{2}$ millions in war, but both numbers are subject to some discount. In one state the war army is returned as a levy *en masse* of the male population, which means not an army, but a disorganized crowd of men with or without rifles and ammunition. On the other hand, Russia or Turkey might with comparative facility increase their numbers in Europe by transporting Asiatic troops, who could migrate westwards without impinging on foreign territory.

The formation of infantry into sections, companies, and battalions, these last growing in strength from 400 to 900, can be traced during the 700 years between the dates of Lycurgus and Polybius. Nestor recommended Agamemnon to accept a territorial system (*Iliad*, ii. 364) by which men and officers from the same district served together. The organization of infantry now generally holding is about 1000 men in each battalion, with either four or eight captain's companies in each; the papers and documents are compiled for the battalion, although large disciplinary power, varying in different countries, is placed in the hands of the company commanders. The range and accuracy of modern firearms enforce a thinner formation, and consequently a more extended one, as science increases the power of both artillery and rifles, and the full effect of smokeless propellants in war has yet to be learned; hence the responsibilities of captains of companies grow visibly, as those officers have command of the largest body that can certainly be influenced by the personality of a single commander under the stress of combat. The working unit of infantry is practically the company, commanded by its captain, and this seems to be common in all armies from Biblical times to the present; the centurion, or commander normally of 100 men, has been a recognized character since history began; sub-units, either half-companies or sections under lieutenants or other subaltern officers, and smaller bodies under sergeants or corporals, may have effective duties both in peace and war. Two, three, or four battalions form a regiment, generally of a territorial nature, and sometimes with some form of additional veteran battalions or militia, as reinforcing bodies in war. The largest pure unit of infantry is a brigade; divisions may contain two or three brigades, but have troops of other arms attached.

The infantry of all countries have at times shown brilliant courage and military qualities, but check or failure seems unduly to affect the troops of some nationalities. In the American Civil War troops of nationalities with high reputation in some portions of the Old World proved often to be broken reeds in times of stress. Since the days of Cæsar and his Xth Legion probably no infantry have deservedly held so dominating a reputation as the Light Division of the Duke of Wellington's army in the Peninsula; but they had a great literary artist as their historian, and he was a gallant member of their noble body. The foundation of war success for infantry, as with all troops, is confidence—well founded on long experience of the officers; Great Britain had, at times, to bear the bitter burden of the reverse, but, for the most part, a resilience supervened in changed circumstances, or the British Empire would not hold the position it now does on the scroll of civilizing powers. In the last Boer War the British infantry proved splendid fighters.

Literature on the subject is profuse; perhaps the best condensation is *Die Fechtweise aller Zeiten*, by Boguslawski. (J. B. S.)

Infants.—There have been various recent modifications in the law of the United Kingdom affecting infants. By the Sale of Goods Act, 1893, an infant liable on a contract for necessaries can be sued only for a reasonable price, not necessarily the price he agreed to pay. The same statute declares "necessaries" to mean "goods suitable to the condition in life of the infant and to his actual requirements at the time of the sale and delivery." In the case of goods having a market price, the market price is reasonable. In all other cases the question is one of fact for the jury. Recent decisions have explained and interpreted the Infants' Relief Act, 1874. For some years after the passage of that statute highly conflicting views were held as to the meaning of the part of section 2 whereby it was enacted that "no action shall be brought whereby to charge any person . . . upon any ratification made after full age of any promise or contract made during infancy." Some authorities were of opinion that the section only applied to the three classes of contract made void by the previous section, viz., for goods supplied, money lent, and on account stated. Others thought the effect to be that no contract, except for necessaries, made during infancy could be enforced after the infant came to full age. After several conflicting decisions it has been settled that both these views were wrong. Of the infant's contracts voidable at common law there were two kinds. The first kind became void at full age, unless expressly ratified. The second kind were valid, unless repudiated within a reasonable time after full age was attained by the infant. The Infants' Relief Act (section 2) strikes only at the first class, and leaves the second untouched. Thus a promise of marriage made during infancy cannot be ratified so as to become actionable; but an infant's marriage settlement, being of the second class, is valid, unless it is repudiated within a reasonable time after the infant attains full age. What is a reasonable time depends on all the circumstances of the case. In a case decided in 1893 a settlement made by a female infant was allowed to be repudiated thirty years after she attained full age, but the circumstances were exceptional.

The Guardianship of Infants Act, 1886, places the mother almost on the same footing as the father as to guardianship of infants. On the death of the father the mother becomes guardian under the statute, either alone when no guardian has been appointed by the father, or

jointly with any guardian appointed by him under 12 Chas. II. c. 24. A change of the law even more important is that whereby the mother may by deed or will appoint a guardian or guardians of her infant children to act after her death. If the father survives the mother, the mother's guardian can only act if it be shown to the satisfaction of the court that the father is unfitted to be the sole guardian. On the death of the father, the guardian so appointed by the mother acts jointly with any guardian appointed by the father. The Guardianship of Infants Act, 1886, also gives power to the High Court and to county courts to make orders, upon the application of the mother, regarding the custody of an infant, and the right of access thereto of either parent. The court must take into consideration "the welfare of the infant, and . . . the conduct of the parents, and . . . the wishes as well of the mother as of the father." The same statute also empowers the High Court of Justice, "on being satisfied that it is for the welfare of the infant," to "remove from his office any testamentary guardian or any guardian appointed or acting by virtue of this Act," and also to appoint another in place of the guardian so removed.

The same statute gives power to a court sitting in divorce practically to take away from a parent guilty of a matrimonial offence all rights of guardianship. When a decree for judicial separation or divorce is pronounced, the court pronouncing it may at the same time declare the parent found guilty of misconduct to be unfit to have the custody of the children of the marriage. "In such case the parent so declared to be unfit shall not, upon the death of the other parent, be entitled as of right to the custody or guardianship of such children." The court exercises this power very sparingly. When the declaration of unfitness is made, the practical effect is to give to the innocent parent the sole guardianship, as well as power to appoint a testamentary guardian to the exclusion of the guilty parent.

Another radical change has recently been made in the rights of parents as to guardianship of their children. In consequence of several cases where, after children had been rescued by philanthropic persons from squalid homes and improper surroundings, the courts had felt bound by law to redeliver them to their parents, the Custody of Children Act, 1891, was passed. It provides that when the parent of a child applies to the court for a writ or order for the production of the child, and the court is of opinion that the parent has abandoned or deserted the child, or that he has otherwise so conducted himself that the court should refuse to enforce his right to the custody of the child, the court may, in its discretion, decline to issue the writ or make the order. If the child, in respect of whom the application is made, is being brought up by another person ("person" includes "school or institution"), or is being boarded out by poor-law guardians, the court may, if it orders the child to be given up to the parent, further order the parent to pay all or part of the cost incurred by such person or guardians in bringing up the child.

A parent who has abandoned or deserted his child is, *primâ facie*, unfit to have the custody of the child. And before the court can make an order giving him the custody, the *onus* lies on him to prove that he is fit. The same rule applies where the child has been allowed by the parent "to be brought up by another person at that person's expense, or by the guardians of a poor-law union, for such a length of time and under such circumstances as to satisfy the court that the parent was unmindful of his parental duties."

The 4th section of the Custody of Children Act, 1891, carefully preserves the right of the parent to control the religious training of the infant. The father, however unfit he may be to have the custody of his child, has the legal right to require the child to be brought up in his own religion. If the father is dead, and has left no directions on the point, the mother may assert a similar right. But the court may, if the child appears capable of understanding the matter, consult the wishes of the child; and when an infant has been allowed by the father to grow up in a faith different from his own, the court will not, as a rule, order any change in the character of religious instruction. This is especially the case where the infant appears, on examination, to be settled in his convictions.

In the same direction as the Custody of Children Act, 1891, is the Prevention of Cruelty to Children Act, 1894, whereby considerable powers have been conferred on courts of summary jurisdiction. Magistrates are empowered to punish parents or other custodians of children for cruelty, to deprive them of the custody of the children, and to remove the children, until they attain the age of sixteen, to other custody.

The Guardianship of Infants Act, 1886, the Custody of Children Act, 1891, and the Prevention of Cruelty to Children Act, 1894, all apply to Scotland. (R. S. D.)

Influenza.—Like cholera and plague, influenza has reappeared, after an interval of many years, in epidemic or rather pandemic form, and has exhibited a far greater power of diffusion and a more generally destructive influence upon life and health than either cholera or plague. The previous severe visitations in Great Britain during the 19th century occurred in 1803, 1833, 1837–38, and 1847–48. After the year 1848, in which 7963 deaths were directly attributed to influenza in England and Wales, the disease continued more or less prevalent until 1860, with distinct but minor epidemic exacerbations in 1851, 1855, and 1858; but during the next decade the mortality dropped rapidly though not steadily, and the diminution continued down to the year 1889, in which only 55 deaths were ascribed to this cause. It is not clear whether the disease ever disappears wholly or not. Every year doctors meet with cases of illness which they call influenza, and the 55 deaths registered in 1889 are the lowest number recorded in any year since the Registrar-General's returns began. Occasionally also local outbreaks of illness resembling epidemic influenza have been observed during the period of abeyance, as, for instance, in Norfolk in 1878 and in Yorkshire in 1887; but whether such outbreaks and the so-called "sporadic" cases that occur every year are nosologically identical with epidemic influenza is open to some doubt. The relation seems rather to be similar to that between Asiatic cholera and "cholera nostras." Individual cases may be indistinguishable, but as a factor in the public health the difference between sporadic and epidemic influenza is quite as great and unmistakable as that between the two forms of cholera. This fact, which had been forgotten by some since 1847 and never learnt by others, was brought home forcibly to all by the visitation of 1889.

The disease began then, though it did not obtain a distinct hold of England until the very close of the year. According to the exhaustive report drawn up by Dr H. Franklin Parsons for the Local Government Board, the earliest appearances were observed in May 1889, and three localities are mentioned as affected at the same time, all exceedingly remote and widely separated from each other —namely, Bokhara in Central Asia, Athabasca in the North-West Territories of Canada, and Greenland. About the middle of October it was reported at Tomsk in

Siberia, and by the end of the month at St Petersburg. During November Russia became generally affected, and cases were noticed in Paris, Berlin, Vienna, London, and Jamaica (?). In December epidemic influenza became fully established over the whole of the continent of Europe, along the Mediterranean, in Egypt, and over a large area in the United States. It also appeared in several towns in England, beginning with Portsmouth, during December, but did not become generally epidemic until the commencement of the new year. In London the full onset of unmistakable influenza dated from 1st January 1890. Everywhere it seems to have exhibited the same explosive character when once fully established. In St Petersburg, out of a Government staff of 260 men, 220 were taken ill in one night, 15th November. During January 1890 the epidemic reached its height in London, and appeared in a large number of provincial towns throughout the British Islands, though it was less prevalent in the north and north-west than in the south. The experience of many Continental countries in the same month was very similar, though, generally speaking, they were somewhat in advance of England. January witnessed a great extension of the disease in Germany, Holland, Switzerland, Austria-Hungary, Italy, Spain, and Portugal; but in Russia, Scandinavia, and France it was already declining. On the whole, the period of greatest activity in Europe was the latter half of December and the earlier half of January, with the change of the year for a central point. Other parts of the world affected in January 1890 were Cape Town, Canada, the United States generally, Algiers, Tunis, Cairo, Corsica, Sardinia, Sicily, Honolulu, Mexico, the West Indies, and Montevideo. In February the provincial towns of England were most severely affected, the death-rate rising to 27·4, but in London it fell from 28·1 to 21·2, and for Europe generally the back of the epidemic was broken. On the other hand, it extended in the Far East at the same time, appearing in Ceylon, Penang, Japan, Hong Kong, and India; also in West Africa, attacking Sierra Leone and Gambia in the middle of the month; and finally in the west, where Newfoundland and Buenos Aires were invaded. In March influenza became widely epidemic in India, particularly in Bengal and Bombay, and made its appearance in Australia and New Zealand. In April and May it was epidemic all over Australasia, in Central America, Brazil, Peru, Arabia, and Burma. During the summer and autumn it reached a number of isolated islands, such as Iceland, St Helena, Mauritius, and Réunion. Eventually, towards the close of the year, it was reported from Yunnan in the interior of China, from the Shiré Highlands in Central Africa, Shoa in Abyssinia, and Gilgit in Kashmir. In the course of fifteen months, if we begin with its undoubted appearance in Siberia in October 1889, it had traversed the entire globe and visited every quarter, however remote.

The localities attacked by influenza in 1889–90 appear in no case to have suffered severely for more than a month or six weeks, the disease then ceasing to be epidemic, if it did not wholly disappear. Thus in Europe and North America generally the visitation had come to an end in the first quarter of 1890, though small local outbreaks were reported here and there later in the year and during the following winter. The earliest signs of an epidemic revival on a large scale occurred about the same time, namely, March 1891, in the United States and the north of England. In the former it was reported from Chicago and other large towns in the central states, whence it spread eastwards, reaching New York about the end of March. In England it began in the Yorkshire towns, particularly in Hull, and also independently in South Wales. In London influenza became epidemic for the second time about the end of April, and soon afterwards was widely distributed in England and Wales. The large towns in the north, together with London and Wales, suffered very much more heavily in mortality than in the previous attack, but the south-west of England, Scotland, and Ireland escaped with comparatively little sickness. The same may be said of the European continent generally, with the exception of parts of Russia, Scandinavia, and perhaps the north of Germany. This second epidemic coincided with the spring and early summer; it had subsided in London by the end of June. The experience of Sheffield is interesting. In 1890 the attack, contrary to general experience, had been undecided, lingering, and mild; in 1891 it was very sudden and extremely severe, the death-rate rising to 73·4 during the month of April, and subsiding with equal rapidity. During the third quarter of the year, while Europe was free, the Antipodes had their second attack, which was more severe than the first. As in England, it reversed the previous order of things, beginning in the provinces and spreading thence to the capital towns. The last quarter of the year was signalized by another recrudescence in Europe, which reached its height during the winter. All parts, including Great Britain, were severely affected. In England it began in the south and south-west in the month of October, and at the same time, or a little earlier, in Scotland at Dundee, and in Ireland at Londonderry. All these parts suffered heavily, together with Northumberland, Durham, and Cumberland, but those which had borne the brunt of the epidemic in the early part of the year escaped. In fact, these two revivals may be regarded as one, temporarily interrupted by the summer quarter.

The recrudescence at the end of 1891 lasted through mid-winter, and in many places, notably in London, it only reached its height in January 1892, subsiding slowly and irregularly in February and March. Brighton suffered with exceptional severity. The Continent seems to have been similarly affected. In Italy the notifications of influenza were as follows: 1891—January to October, 0; November, 30; December, 6461; 1892—January, 84,543; February, 55,352; March, 28,046; April, 7962; May, 1468; June, 223. Other parts of the world affected were the West Indies, Tunis, Egypt, Sudan, Cape Town, Tehran, Tongking, and China. In August 1892 influenza was reported from Peru, and later in the year from various places in Europe.

A fourth recrudescence, but of a milder character, occurred in Great Britain in the spring of 1893, and a fifth in the following winter, but the year 1894 was freer from influenza than any since 1890. In 1895 another extensive epidemic took place. In 1896 the enemy seemed to have spent its strength, and hopes were entertained that it was dying out, but these were falsified by an increased prevalence in 1897, which was repeated on a larger scale in 1898, and again in 1899, when 12,417 deaths were recorded in England and Wales. The experience of other countries has been very similar; they have all been subjected to periodical revivals of epidemic influenza at irregular intervals and of varying intensity since its original reappearance in 1889, but on the whole there has been a general though not a steady decline in its activity and potency. Its behaviour is, in short, quite in keeping with the experience of 1847–60, though the later visitation appears to have been considerably more violent and more fatal than the former. Its diffusion was also more rapid and probably more extensive.

The foregoing general summary may be supplemented by some further details of the incidence in Great Britain. The number of deaths directly attributed to influenza,

and the death-rates per million in each year in England and Wales, are as follows :—

	1890.	1891.	1892.	1893.	1894.	1895.	1896.	1897.	1898.
Deaths . .	4523	16,686	15,737	9669	6625	12,880	3753	6088	10,405
Death-rates per million	157	574	534	325	220	424	122	196	331

It is interesting to compare these figures with the corresponding ones for the previous visitation :—

	1847.	1848.	1849.	1850.	1851.	1852.	1853.	1854.	1855.
Deaths . .	4881	7963	1611	1380	2152	1359	1789	1061	3568
Death-rates per million .	285	460	92	78	120	76	99	58	193

The two sets of figures are not strictly comparable, because registration was in its infancy during the first period, and notification of the cause of death was not made compulsory until many years later; but it seems clear that, when all allowances have been made, the later wave was much the more deadly. The average annual death-rate for the nine years is 320 in the one case against 162 in the other, or as nearly as possible double. In both epidemic periods the second year was far more fatal than the first, and in both a marked revival took place in the ninth year; in both also an intermediate recrudescence occurred, in the fifth year in one case, in the sixth in the other. The chief point of difference is the sudden and marked drop in 1849–50, against a persistent high mortality in 1892–93, especially in 1892, which was nearly as fatal as 1891.

To make the significance of these epidemic figures clear, it should be added that in the intervening period 1861–89 the average annual death-rate from influenza was only fifteen, and in the ten years immediately preceding the 1890 outbreak it was only three. Moreover, in epidemic influenza the mortality directly attributed to that disease is only a fraction of that actually caused by it. For instance, in January 1890 the deaths from influenza in London were 304, while the excess of deaths from respiratory diseases was 1454 and from all causes 1958 above the average.

We have seen above that the mortality was far greater in the second epidemic year than in the first, and this applies to all parts of England, and to rural as well as to urban communities, as the following table shows :—

	Deaths from Influenza.	
	1890.	1891.
London	624	2302
24 Great Towns over 80,000 population .	439	2417
35 Towns between 20,000 and 80,000 .	186	765
21 Towns between 10,000 and 20,000 .	46	196
60 Towns under 10,000	62	196
85 Rural Sanitary Districts . . .	317	841

In spite of these figures, it appears that the 1890 attack, which was, generally speaking, much more sudden in its onset than that of 1891, also caused a great deal more sickness. More people were "down with influenza," though fewer died. For instance, the number of persons treated at the Middlesex Hospital in the two months' winter epidemic of 1890 was 1279; in the far more fatal three months' spring epidemic of 1891 it was only 726. One explanation of this discrepancy between the incidence of sickness and mortality is that in the second attack, which was more protracted and more insidious, the stress of the disease fell more upon the lungs, and so led to more fatal results. Another is that its comparative mildness, combined with the time of year, in itself proved dangerous, because it tempted people to disregard the illness, whereas in the first epidemic they were too decidedly ill to resist. It may also be that there was some change in the practice of medical men with regard to certifying, and more readiness on their part to record influenza as a cause of death in the second year, when they understood it better. On the whole, rural districts showed a higher death-rate than towns, and small towns a higher one than large ones in both years. This is explained by the age distribution in such localities; there are more old people, to whom influenza is particularly fatal. Certain counties were much more severely affected than others. The eastern counties, namely, Essex, Suffolk, and Norfolk, together with Hampshire and one or two others, escaped lightly in both years; the western counties, namely, North and South Wales, with the adjoining counties of Monmouth, Hereford, and Shropshire, suffered heavily in both years.

It will be convenient to discuss *seriatim* the various points of interest on which light has been thrown by the experience described above.

The bacteriology of influenza is discussed in its proper place under PATHOLOGY (*Parasitic Diseases*). The disease is often called Russian influenza, and its origin in 1889 suggests that the name may have some foundation in fact. According to information collected by Dr Parsons, it came to Europe by way of Siberia and Russia, having been first recognized in Central Asia. A writer, who saw the epidemic break out in Bokhara, is quoted by him to the following effect:—"The summer of 1888 was exceptionally hot and dry, and was followed by a bitterly cold winter and a rainy spring. The dried-up earth was full of cracks and holes from drought and subsequent frost, so that the spring rains formed ponds in these holes, inundated the new railway cuttings, and turned the country into a perfect marsh. When the hot weather set in the water gave off poisonous exhalations, rendering malaria general." On account of the severe winter, the people were enfeebled from lack of nourishment, and when influenza broke out suddenly they died in large numbers. Europeans were very severely affected, the entire household of the Russian Legation being in bed at one time. Russian officials and others, hurrying home, carried the disease westwards, and caravans passing eastwards took it into Siberia. One cannot but be struck by the similarity of the conditions described to those observed in connexion with outbreaks of other diseases, particularly typhoid fever and diphtheria, which have occurred on the supervention of heavy rain after a dry period, causing cracks and fissures in the earth. Assuming the existence of a living poison in the ground, we can easily understand that under certain conditions, such as an exceptionally dry season, it may develop exceptional properties and then be driven out by the subsequent rains, causing a violent outbreak of illness. Some such explanation is required to account for the periodical occurrence of epidemic and pandemic diffusions starting from an endemic centre. We may suppose that a micro-organism of peculiar robustness and virulence is bred and brought into activity by a combination of favourable conditions, and is then disseminated, more or less widely according to its "staying power," by human agency. Whether Central Asia is an endemic centre for influenza or not there is no evidence to show, but the disease seems to be undoubtedly more often prevalent in the Russian Empire than elsewhere. Extensive outbreaks occurred there in 1886 and 1887, and it is certain that the 1889 wave was active in Siberia at an earlier date than in Europe, and that it moved eastwards. The hypothesis that it originated in China is unsupported by any evidence. But whatever may be the truth with regard to origin, the dissemination of influenza

by human agency must be held to be proved. The establishment of this fact is the most important addition to our knowledge of the subject that has been contributed by recent research. We owe it to the investigations of Dr Parsons, who carefully traced the movements of the 1889–90 epidemic from place to place and examined the various conditions under which it prevailed. The upshot of his inquiry was to negative all theories of atmospheric influence, and to establish the conclusion that the disease was "propagated mainly, perhaps entirely, by human intercourse." He found that it prevailed independently of climate, season, and weather; that it moved in a contrary direction to the prevailing winds; that it travelled along the lines of human intercourse, and not faster than human beings can travel; that in 1889 it travelled much faster than in previous epidemics, when the means of locomotion were very inferior; that it appeared first in capital towns, seaports, and frontier towns, and only affected country districts later; that it never commenced suddenly with a large number of cases in a place previously free from disease, but that epidemic manifestations were generally preceded for some days or weeks by a succession of scattered cases; that conveyance of infection by individuals and its introduction into fresh places had been observed in many instances; that persons brought much into contact with others were generally the first to suffer in a household or establishment; that persons brought together in large numbers in enclosed spaces, as in public offices and institutions, suffered more in proportion than others, and that the rapidity and extent of the outbreak in institutions corresponded with the massing together of the inmates. These conclusions, based upon the 1889–90 epidemic, have been confirmed by subsequent experience, especially in regard to the complete independence of season and weather shown by influenza. It has appeared and disappeared at all seasons and in all weathers—warm, cold, wet, dry, changeable, windy, still, foggy, and clear—and only popular ignorance continues to ascribe its behaviour to atmospheric conditions. In Europe, however, it has prevailed more often in winter than in summer, which may be due to the greater susceptibility of persons in winter, or, more probably, to the fact that they congregate together more in buildings and are less in the open air during that part of the year. No doubt is any longer entertained of its infectious character, though the degree of infectivity appears to vary considerably. Many cases have been recorded of individuals introducing it into houses, and of all or most of the other inmates then taking it from the first case. In other instances it has failed to spread in large households, in spite of close and constant contact of other persons with the sick. This difference in behaviour may possibly be explained by differences in the type of illness, the "catarrhal" form, in which the air-passages are affected, being more infectious than those in which the stress falls on the nervous or intestinal systems, just as the "pneumonic" form of plague is more infectious than the other varieties. How far the infection of influenza is air-borne has not been determined, but the evidence tends to negative the hypothesis that it can be conveyed any considerable distance. On the other hand, cases have been recorded which go far to prove the dissemination by means of infected articles of clothing, letters, and the like. Of the lower animals, horses are liable to an inflammation of the mucous membrane, known as "pink eye," which has prevailed at the same time as influenza; but whether the two are connected has not been definitely ascertained. Other domestic animals seem to be free from any suspicion. Sanitary conditions, other than overcrowding, do not appear to exercise any influence on the spread of influenza.

Influenza has been clearly shown to be an acute specific fever, having nothing whatever to do with a "bad cold." There may be some inflammation of the respiratory passages, and then symptoms of catarrh are present, but that is not necessarily the case, and in some epidemics such symptoms are quite exceptional. This had been recognized by various writers before the 1889 visitation, but it had not been generally realized, as it has been since, and some medical authorities, who persisted in regarding influenza as essentially a "catarrhal" affection, were chiefly to blame for a widespread and tenacious popular fallacy. The "period of incubation" is indeterminate, as usual. The most common interval between exposure to infection and onset of symptoms seems to be two or three days, but it may be much less or much more. On this head it may be remarked that recent demonstrations of the capacity of some people to be infected with specific microbes for an indefinite time without showing any symptoms go far to explain the elasticity of "periods of incubation," and make any attempt at precision a little ridiculous. Susceptibility varies greatly, but the conditions that influence it are matters of conjecture only. It appears that the inhabitants of Great Britain are less susceptible than those of many other countries. Dr Parsons gives the following list, showing the proportion of the population estimated to have been attacked in the 1889–90 epidemic in different localities:—

Place.	Per Cent.	Place.	Per Cent.
St Petersburg	50	Portugal	90
Berlin	33	Vienna	30–40
Nuremberg	67	Belgrade	33
Grand-Duchy of Hesse	25–30	Antwerp	33
Grand-Duchy, other Districts	50–75	Gaeta	50–77
		Massachusetts	39
Heligoland	50	Peking	50
Budapest	50	St Louis (Mauritius)	67

In and about London he reckons roughly from a number of returns that the proportion was about 12½ per cent. among those employed out of doors and 25 per cent. among those in offices, &c. The proportion among the troops in the Home District was 9·3 per cent. The General Post Office made the highest return with 33·6 per cent., which is accounted for partly by the enormous number of persons massed together in the same room in more than one department, and partly by the facilities for obtaining medical advice, which would tend to bring very light cases, unnoticed elsewhere, upon the record. No public service was seriously disorganized in England by sickness in the same manner as on the Continent, though much inconvenience was caused at the height of the first epidemic. In subsequent ones, as has already been observed, there was less illness, though more mortality. Some individuals appear to be totally immune; others take the disease over and over again, deriving no immunity, but apparently greater susceptibility from previous attacks.

The symptoms were thus described by Dr Bruce Low from observations made in St Thomas's Hospital, London, in January 1890:—

The invasion is sudden; the patients can generally tell the time when they developed the disease; *e.g.*, acute pains in the back and loins came on quite suddenly while they were at work or walking in the street, or in the case of a medical student, while playing cards, rendering him unable to continue the game. A workman wheeling a barrow had to put it down and leave it; and an omnibus driver was unable to pull up his horses. This sudden onset is often accompanied by vertigo and nausea, and sometimes actual vomiting of bilious matter. There are pains in the limbs and general sense of aching all over; frontal headache of special severity; pains in the eyeballs, increased by the slightest movement of the eyes; shivering; general feeling of misery and weakness, and

great depression of spirits, many patients, both men and women, giving way to weeping; nervous restlessness; inability to sleep, and occasionally delirium. In some cases catarrhal symptoms develop, such as running at the eyes, which are sometimes injected on the second day; sneezing and sore throat; and epistaxis, swelling of the parotid and submaxillary glands, tonsilitis, and spitting of bright blood from the pharynx may occur. There is a hard, dry cough of a paroxysmal kind, worst at night. There is often tenderness of the spleen, which is almost always found enlarged, and this persists after the acute symptoms have passed. The temperature is high at the onset of the disease. In the first twenty-four hours its range is from 100° F. in mild cases to 105° in severe cases.

Dr J. S. Bristowe gave the following description of the illness during the same epidemic :—

The chief symptoms of influenza are, coldness along the back, with shivering, which may continue off and on for two or three days; severe pain in the head and eyes, often with tenderness in the eyes and pain in moving them; pains in the ears; pains in the small of the back; pains in the limbs, for the most part in the fleshy portions, but also in the bones and joints, and even in the fingers and toes; and febrile temperature, which may in the early period rise to 104° or 105° F. At the same time the patient feels excessively ill and prostrate, is apt to suffer from nausea or sickness and diarrhœa, and is for the most part restless, though often (and especially in the case of children and those advanced in age) drowsy. . . . In ordinary mild cases the above symptoms are the only important ones which present themselves, and the patient may recover in the course of three or four days. He may even have it so mildly that, although feeling very ill, he is able to go about his ordinary work. In some cases the patients have additionally some dryness or soreness of the throat, or some stiffness and discharge from the nose, which may be accompanied by slight bleeding. And in some cases, for the most part in the course of a few days, and at a time when the patient seems to be convalescent, he begins to suffer from wheezing in the chest, cough, and perhaps a little shortness of breath, and before long spits mucus in which are contained pellets streaked or tinged with blood. . . . Another complication is diarrhœa. Another is a roseolous spotty rash. . . . Influenza is by no means necessarily attended with the catarrhal symptoms which the general public have been taught to regard as its distinctive signs, and in a very large proportion of cases no catarrhal condition whatever becomes developed at any time.

Several writers have distinguished three main varieties of the disease—namely, (1) nervous, (2) gastric, (3) catarrhal, according to the predominant symptoms. Perhaps the most marked feature of influenza, and certainly the one which victims have learned to dread most, is the prolonged debility and nervous depression that frequently follow an attack. Other common after-effects are neuralgia, dyspepsia, insomnia, weakness or loss of the special senses, particularly taste and smell, abdominal pains, sore throat, rheumatism, and muscular weakness. The feature most dangerous to life is the special liability of patients to inflammation of the lungs. This affection, dangerous at all times, and particularly so in persons weakened by influenza, must be regarded as a complication rather than an integral part of the illness. No age is exempt, but the mortality is much greater among elderly persons than among the young, and it increases with advancing years. The following table shows the proportional mortality per 1000 living at different ages, and for each sex, in 1891 :—

Proportional Mortality per 1000 *Living*, 1891.

	All Ages.	0–5.	5–10.	10–15.	15–20.	20–25.	25–35.	35–45.	45–55.	55–65.	65–75.	75–85.	85– .
Males .	·61	·54	·07	·07	·17	·20	·32	·62	1·11	1·91	3·43	5·71	6·93
Females .	·54	·38	·09	·09	·14	·17	·26	·42	·79	1·54	3·12	5·17	7·91
Both Sexes	·57	·46	·08	·08	·15	·19	·29	·52	·94	1·73	3·27	5·40	7·60

This table shows that influenza is least fatal to children between five and fifteen years, that younger children suffer more, and that after fifteen the proportional mortality rises steadily and rapidly. With regard to sex, the disease is on the whole more fatal to males than to females; but this is obviously due to habits of life, and particularly to the greater exposure suffered by men in the period of greatest activity. The higher male mortality begins to assert itself just when boys first go out to earn a living, and the difference increases up to sixty-five, after which the two approximate again, and eventually the female mortality is the higher of the two, as it was in childhood.

The deaths directly attributed to influenza are few in proportion to the number of cases, though the aggregate mortality is large on account of its universal prevalence. In the milder forms it offers hardly any danger to life if reasonable care be taken, but in the severer forms it is a fairly fatal disease. In eight London hospitals the case-mortality among in-patients in the 1890 outbreak was 34·5 per 1000; among all patients treated it was 1·6 per 1000. In the army it was rather less.

There is no routine treatment for influenza except bed. In all cases bed is advisable, because of the danger of lung complications, and in mild ones it is sufficient. Severer ones must be treated according to the symptoms. Quinine has been much used, but its efficacy is doubtful. Modern "anti-pyretic" drugs have also been extensively employed, and when applied with discretion they may be useful, but patients are not advised to prescribe them for themselves. The chief lesson derived from experience is the need for care during convalescence and the danger of trying to resist the disease or underrating its seriousness.

The infectious character of influenza having been determined, suggestions were made for its administrative control on the familiar lines of notification, isolation, and disinfection, but this has not hitherto been found practicable. In March 1895, however, the Local Government Board issued a memorandum recommending the adoption of the following precautions wherever they can be carried out :—

1. The sick should be separated from the healthy. This is especially important in the case of first attacks in a locality or a household.

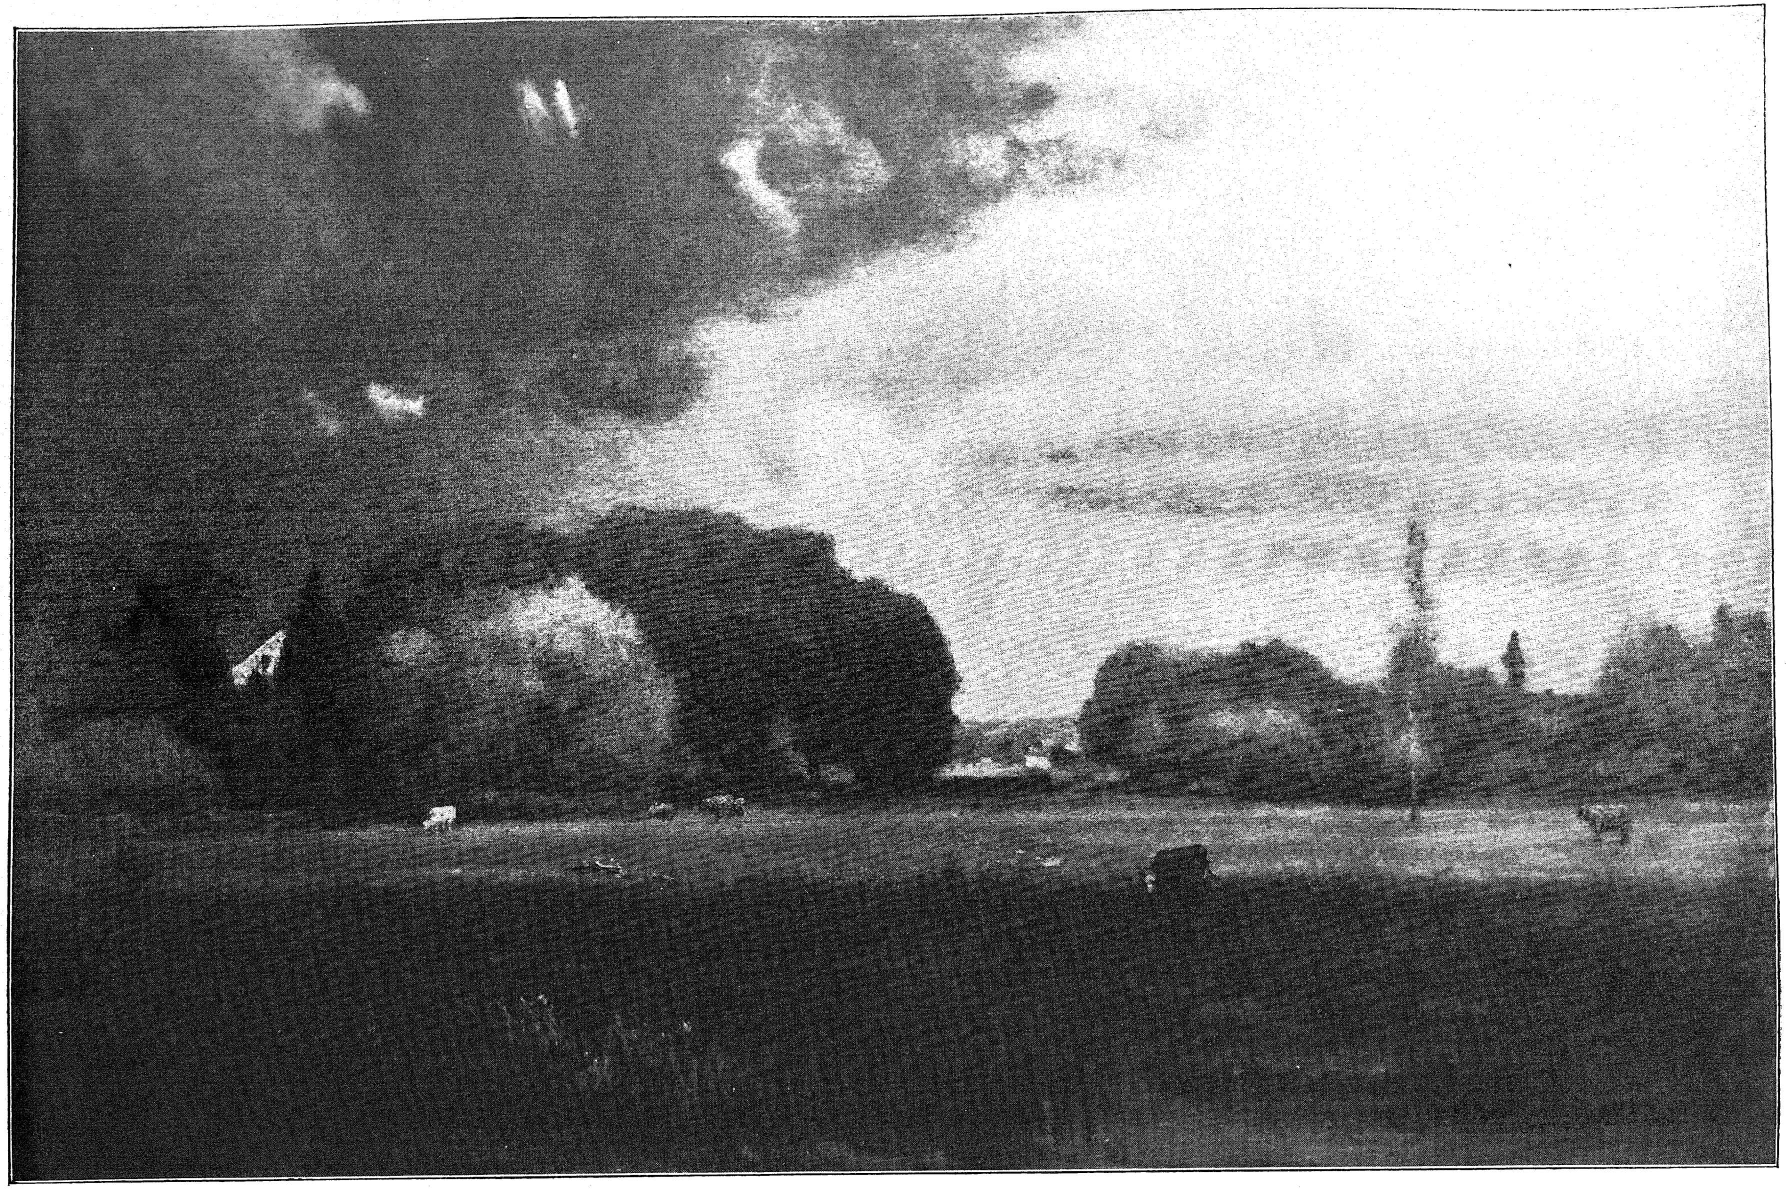
2. The sputa of the sick should, especially in the acute stage of the disease, be received into vessels containing disinfectants. Infected articles and rooms should be cleansed and disinfected.

3. When influenza threatens, unnecessary assemblages of persons should be avoided.

4. Buildings and rooms in which many people necessarily congregate should be efficiently aërated and cleansed during the intervals of occupation.

It should also be borne in mind that the liability to contract influenza, and the danger of an attack if contracted, are increased by depressing conditions, such as exposure to cold and to fatigue, whether mental or physical. Attention should therefore be paid to all measures tending to the maintenance of health, such as the use of clothing of suitable warmth and a sufficiency of wholesome food. Persons who are attacked by influenza should at once seek rest, warmth, and medical treatment, and they should bear in mind that the risk of relapse, with serious complications, constitutes a chief danger of the disease. It may be added that influenza is no respecter of persons. It levels all ranks, and nothing has been more striking in the visitations than the large number of prominent and exalted personages whom it has attacked with disabling or fatal results, among the victims being the heirs to two European thrones—those of the United Kingdom and Belgium. (A. SL)

Ingelow, Jean (1820–1897), English poet and novelist, was born at Boston, in Lincolnshire, in 1820, being the daughter of William Ingelow, a banker of that



"THE MEDFIELD MEADOWS." BY GEORGE INNESS.

(From a Copley Print of the Painting, copyright 1899 by Curtis and Cameron.)

town. As a girl she contributed verses and tales to the magazines under the pseudonym of "Orris," but her first (anonymous) volume, *A Rhyming Chronicle of Incidents and Feelings*, did not appear until her thirtieth year. This Tennyson said had "very charming things" in it, and declared he should "like to know" the author, who was later admitted to his friendship. Miss Ingelow followed this book of verse in 1851 with a story, *Allerton and Dreux*, but it was the publication of her *Poems* in 1863 which suddenly raised her to the rank of a popular writer. They ran rapidly through numerous editions, were set to music, and sung in every drawing-room, and in America obtained an even greater hold upon public estimation. In 1867 she published *The Story of Doom and other Poems*, and then gave up verse for a while and became industrious as a novelist. *Off the Skelligs* appeared in 1872, *Fated to be Free* in 1873, *Sarah de Berenger* in 1880, and *John Jerome* in 1886. In addition to these she wrote *Studies for Stories* (1864), *Stories told to a Child* (1865), *Mopsa the Fairy* (1869), and other stories for children—a form of literature in which she excelled. Her third series of *Poems* was published in 1885. She resided for the last years of her life in Kensington, and somewhat outlived her popularity as a poet. She died 20th July 1897. Her poetry has often the genuine ballad note, and as a writer of songs she was exceedingly successful. "Sailing beyond Seas," and "When Sparrows build" in *Supper at the Mill* were deservedly among the most popular songs of the day; but they share, with the rest of her work, the faults of affectation and stilted phraseology. Her best-known poem was the "High Tide on the Coast of Lincolnshire," which reached the highest level of excellence. The blemishes of her style were cleverly indicated in a well-known parody of Calverley's; a false archaism and a deliberate assumption of unfamiliar and unnecessary synonyms for simple objects were among the most vicious of her mannerisms. She wrote, however, in verse with a sweetness which her sentiment and her heart inspired, and in prose she displayed feeling for character and the gift of narrative; while a delicate underlying tenderness is never wanting in either medium to her sometimes tortured expression. Miss Ingelow was a woman of frank and hospitable manners, with a look of the Lady Bountiful of a country parish. She had nothing of the professional authoress or the "literary lady" about her, and, as with characteristic simplicity she was accustomed to say, was no great reader. Her temperament was rather that of the improvisatore than of the professional author or artist. (A. WA)

Ingersoll, a town and port of entry of Oxford county, Ontario, Canada, 19 miles east of London, on the river Thames and the Grand Trunk and Canadian Pacific railways. The principal manufactures are agricultural implements, furniture, pianos, and screws. There is a large export trade in cheese and farm produce. Exports in 1899–1900 were valued at $2,427,335. Population (1881), 4318; (1901), 4572.

Ingersoll, Robert Green (1833–1899), American lawyer and lecturer, was born in Dresden, New York, 11th August 1833. His father was a Congregational minister, who moved west when Robert was ten years old, and the latter entered the practice of law and politics in Illinois. During the Civil War he organized a cavalry regiment, of which for a short time he was colonel. He was appointed attorney-general of Illinois in 1866, and in 1876 his speech in the Republican National Convention, naming James G. Blaine for the Presidential nomination, won him a national reputation as a public speaker. He was most widely known, however, for his public lectures attacking the Bible, and his anti-Christian views were an obstacle to his political advancement. Ingersoll was an eloquent rhetorician rather than a logical reasoner. His principal lectures and speeches included *The Gods and other Lectures* (1876); *Some Mistakes of Moses* (1879); *Prose Poems* (1884); *Great Speeches* (1887); *The Bible; Ghosts; Foundations of Faith.* He died at Dobbs Ferry, New York, 21st July 1899.

Ingolstadt, a fortified town of Upper Bavaria, Germany, on the left bank of the Danube, 52 miles by rail north from Munich. Its newer public buildings embrace an Evangelical church, a civil hospital, an arsenal, and an orphanage. The industries are cannon-founding, manufacture of gunpowder and cloth, and brewing. Population (1885), 16,388; (1900), 22,206.

Innerleithen, a police burgh and health resort of Peeblesshire, Scotland, on the Leithen water, half a mile from its junction with the Tweed. It is arbitrarily identified with the St Ronans of Sir Walter Scott's novel. The stronger of its two medicinal springs contains 216·72 grains of chloride of sodium, 148·16 of chloride of calcium, 16·17 of magnesium, 1·15 of sulphate of magnesia, 5·03 of carbonate of lime per gallon of water. There are five woollen mills, turning out tweeds and fine yarns. The churches are Established, United Free, Congregational, and Roman Catholic. The public school had an average attendance of 452 in 1898–99. Population (1901), 2181.

Inness, George (1825–1894), American landscape painter, was born near Newburgh, N.Y., 1st May 1825. Before he was five years of age his parents had moved to New York and afterwards to Newark, N.J., in which latter city his boyhood was passed. He would not "take education" at the town academy, nor was he a success as a greengrocer's boy. He had a strong bent towards art, and his parents finally placed him with a drawing-master named Barker. At sixteen he went to New York to study engraving, but soon returned to Newark, where he continued sketching and painting after his own initiative. In 1843 he was again in New York, and is said to have passed a month in Gignoux's studio. What he learned from these masters no one knows. He was too impetuous, too independent in thought, to accept teaching; and, besides, the knowledge of his teachers must have been limited. Practically he was self-taught, and always remained a student. In 1851 he went to Europe, and in Italy got his first glimpse of real art. He was there two years, and naturally imbibed some traditions of the classic landscape, as his pictures of this period show. In 1854 he went to France, and there studied the Barbizon painters, whom he greatly admired, especially Daubigny and Rousseau. After his return to America he opened a studio in New York, then went to Medfield, Mass., where he resided for five years. A pastoral landscape near this town inspired the characteristic painting reproduced in the Plate—"The Medfield Meadows." Again he went abroad and spent six years in Europe. He came back to New York in 1876, and lived there, or near there, until his death, which took place at Bridge of Allan on 3rd August 1894 while travelling in Scotland. He was a National Academician, a member of the Society of American Artists, and had received many honours at home and abroad. He was married twice, his son, George Inness, jun., being also a painter. Inness was emphatically a man of temperament, of moods, enthusiasms, convictions. He was fond of speculation and experiment in metaphysics and religion, as in poetry and art. Swedenborgianism, symbolism, socialism, appealed to him as they might to a mystic or an idealist. He aspired to the perfect unities, and was impatient of structural

foundations. This was his attitude towards painting. He sought the sentiment, the light, air, and colour of nature, but was put out by nature's forms. How to subordinate form without causing weakness was his problem, as it was Corot's. His early education gave him no great technical facility, so that he never was satisfied with his achievement. He worked over his pictures incessantly, retouching with paint, pencil, coal, ink—anything that would give the desired effect—yet never content with them. In his latter days it was almost impossible to get a picture away from him, and after his death his studio was found to be full of experimental canvases. He was a very uneven painter, and his experiments were not always successful. His was an original—a distinctly American—mind in art. His point of view was his own. At his best he was often excellent in poetic sentiment, and superb in light, air, and colour. He had several styles: at first he was somewhat grandiloquent in Roman scenes, but sombre in colour; then under French influence his brush grew looser, as in the "Grey Lowering Day"; finally he broke out in full colour and light, as in the "Niagara" and the last "Delaware Water-Gap." Some of his pictures are in American museums, but most of them are in private hands. (J. C. VAN D.)

Innsbruck, the capital of Tirol, Austria, and one of the most beautifully situated towns in Europe. It is on the Brenner line and $109\frac{1}{2}$ miles by rail from Munich. Among the twenty-eight statues round the cenotaph of Maximilian is one of King Arthur of Britain. Hofer and his companions are actually buried beneath the monuments set up in their honour. The university is now attended by about 1000 students. Innsbruck has little commercial or industrial importance, being rather a political and military stronghold, and having a permanent garrison of about 2000 men. It stands at a height of 1880 feet above the sea-level. In 1890 its population (including the garrison) amounted to 23,320 souls, mainly Romanist and German-speaking; there were but 309 Protestants and 100 Jews, while 458 persons spoke Italian or Ladin, and 497 more persons languages other than German, Italian, or Ladin. In 1900 the population was 27,056.

Inowrazlaw, formerly JUNG-BRESLAU, a town of Prussia, province of Posen, 21 miles by rail south-west of Thorn. It has mines of rock-salt and iron pyrites, flour mills, distilleries, iron foundries, and manufactures of saltpetre and machinery; also, an active trade in agricultural produce. Population (1885), 13,548; (1900), 26,140.

INSANITY.

LEGAL DEVELOPMENTS.

IT is proposed in this article to deal with the changes in the law of lunacy since the article in the earlier volumes of the *Encyclopædia Britannica* (9th ed., vol. xiii. pp. 111–113) was published. For convenience sake the arrangement adopted in the original article has been followed. The only point in which the introductory remarks need to be supplemented is with regard to the chief legal terms respecting persons suffering under mental disabilities. The subject is now of less importance than formerly, because the modern tendency of the law is to determine the capacity or responsibility of a person alleged to be insane by considering it with reference to the particular matter or class of matters which brings his mental condition *sub judice*. But the literature of the law of lunacy cannot be clearly understood unless the distinctions between the different terms employed to describe the insane are kept in view. The term *non compos mentis* is as old as the statute *De Prærogativâ Regis* (17 Edw. II. cc. 9 and 10) and is used sometimes, as in that statute, to indicate a species contrasted with idiot, sometimes (*e.g.*, in Co. Litt. 246 (*b*)) as a genus, and afterwards, chiefly in statutes relating to the insane, in connexion with the terms "idiot" and "lunatic" as a word *ejusdem generis*. The word "idiot" (Greek, ἴδιος, a private person, one who does not hold any public office, and ἰδιώτης, an ignorant and illiterate person) appears in the statute *De Prærogativâ Regis* as *fatuus naturalis*, and it is placed in contradistinction to *non compos mentis*. The "idiot" is defined by Coke (4 *Rep.* 124 (*b*)) as one who from his nativity, by a perpetual infirmity, is *non compos mentis*, and Hale (*Pleas of the Crown*, i. p. 29) describes idiocy as "fatuity *a nativitate vel dementia naturalis.*" In early times various artificial criteria of idiocy were suggested. Fitzherbert's test was the capacity of the alleged idiot to count twenty pence, or tell his age, or who were his father and mother (*De Naturâ Brevium*, 233). Swinburne proposed as a criterion of capacity, *inter alia*, to measure a yard of cloth or name the days in the week (*Testaments*, 42). Hale propounded the sounder view that "idiocy or not is a question of fact triable by jury and sometimes by inspection" (*Pleas of the Crown*, i. p. 29). The legal incidents of idiocy were at one time distinct in an important particular from those of lunacy. Under the statute *De Prærogativâ Regis* the king was to have the rents and profits of an idiot's lands to his own use during the life of the idiot, subject merely to an obligation to provide him with necessaries. In the case of the lunatic the king was a trustee, holding his lands and tenements for his benefit and that of his family. It was on account of this difference in the legal consequences of the two states that on inquisitions distinct writs, one *de idiotâ inquirendo*, the other *de lunatico inquirendo*, were framed for each of them. But juries avoided finding a verdict of idiocy wherever they could, and the writ *de idiotâ inquirendo* fell into desuetude. A further blow was struck at the distinction when it came to be recognized even by the legislature (see the Idiots Act, 1886) as a scientific fact that idiots are capable of being educated and trained, and it was practically abolished when the Lunacy Regulation Act, 1862, in a provision reproduced in substance in the Lunacy Act, 1890, limited the evidence admissible in proof of unsoundness of mind on an inquisition (without special leave of the Master trying the case) to a period of two years before the date of the inquiry, and raised a uniform issue, viz., the state of mind of the alleged lunatic at the time when the inquisition is held.

The term "lunatic," derived from the Latin *luna* in consequence of the notion that the moon had an influence on mental disorders,[1] does not appear in the statute-book till the time of Henry VIII. (33 Hen. VIII. c. 20). Coke defines a lunatic as a "person who has sometimes his understanding and sometimes not, *qui gaudet lucidis intervallis*, and therefore he is called *non compos mentis* so long as he has not understanding" (Co. Litt. 247 (*a*), 4 *Rep.* 124 (*b*)). Hale defines "lunacy" as "interpolated" (*i.e.*, intermittent) *dementia accidentalis vel adventitia*, whether total or (a description, it will be observed, of

[1] The word for "lunatic" in several other languages has a similar etymology. Cp. Italian *lunatico*, Spanish *alunado*, Greek σεληνιακός (epileptic), German *mondsüchtig*.

"partial insanity") *quoad hoc vel illud* (*Pleas of the Crown*, i. p. 29). In modern times the word "lunacy" has lost its former precise signification. It is employed sometimes in the strict sense, sometimes in contradistinction to "idiocy" or "imbecility"; once at least—viz., in the Lunacy Act, 1890—as including "idiot"; and frequently in conjunction with the vague terms "unsound mind" (non-sane memory) and "insane." Section 116 of the Lunacy Act, 1890, has by implication extended the meaning of the term lunacy so as to include for certain purposes the incapacity of a person to manage his affairs through mental infirmity arising from disease or age. "Imbecility" is a state of mental weakness "between the limits of absolute idiocy on the one hand and of perfect capacity on the other" (see 1 Haggard *Eccles. Rep.* p. 401).

The law as to the criminal responsibility of the insane has pursued in England a curious course of development. The views of Coke and Hale give the best exposition of it in the 17th century. Both were agreed that in criminal causes the act and wrong of a madman shall not be imputed to him; both distinguished, although in different language, between *dementia naturalis* (or *a nativitate*) and *dementia accidentalis* or *adventitia;* and the main points in which the writings of Hale mark an advance on those of Coke are in the elaboration by the former of the doctrine of "partial insanity," and his adoption of the level of understanding of a child of fourteen years of age as the test of responsibility in criminal cases (*Pleas of the Crown*, i. pp. 29, 30; and see Co. 4 *Rep.* 124 (*b*)). In the 18th century a test, still more unsatisfactory than this "child of fourteen" theory, with its identification of "healthy immaturity" with "diseased maturity" (Steph. *Hist. Crim. Law*, vol. ii. p. 150), was prescribed. On the trial of Edward Arnold in 1723 for firing at and wounding Lord Onslow, Mr Justice Tracy told the jury that "a prisoner, in order to be acquitted on the ground of insanity, must be a man that is totally deprived of his understanding and memory, and doth not know what he is doing, no more than an infant, than a brute or wild beast." In the beginning of the 19th century a fresh statement of the test of criminal responsibility in mental disease was attempted. On the trial of Hadfield for shooting at George III. in Drury Lane Theatre on 15th May 1800, Lord Chief Justice Kenyon charged the jury in the following terms: "If a man is in a deranged state of mind at the time, he is not criminally answerable for his acts; but the material part of the case is whether at the very time when the act was committed the man's mind was sane." The practical effect of this ruling, had it been followed, would have been to make the question of the amenability of persons alleged to be insane to the criminal law very much one of fact, to be answered by juries according to the particular circumstances of each case, and without being aided or embarrassed by any rigid external standard. But in 1812, on the trial of Bellingham for the murder of Mr Perceval, the First Lord of the Treasury, by shooting him in the Lobby of the House of Commons, Sir James Mansfield propounded yet another criterion of criminal responsibility in mental disease, viz., whether a prisoner has, at the time of committing an offence, a sufficient degree of capacity to distinguish between good and evil. The objection to this doctrine, of course, consisted in the fact, to which the writings of Continental and American jurists soon afterwards began to give prominence, that there are very many lunatics whose general ideas on the subject of right and wrong are quite unexceptionable, but who are yet unable, in consequence of delusions, to perceive the wrongness of particular acts. Sir James Mansfield's statement of the law was discredited in the case of Daniel Macnaughton, who was tried in March 1843, before Chief Justice Tindal, Mr Justice Williams, and Mr Justice Coleridge, for the murder of Mr Drummond, the private secretary of Sir Robert Peel. Mr (afterwards Lord Chief Justice) Cockburn, who defended the prisoner, used Hale's doctrine of partial insanity as the foundation of the defence, and secured an acquittal, Chief Justice Tindal telling the jury that the question was whether Macnaughton was capable of distinguishing right from wrong *with respect to the act with which he stood charged.* This judicial approval of the doctrine of partial insanity formed the subject of an animated debate in the House of Lords, and in the end certain questions were put by that House to the judges, and answered by Chief Justice Tindal on behalf of all his colleagues except Mr Justice Maule, who gave independent replies. The answers to these questions are commonly called "The Rules in Macnaughton's case," and they still nominally contain the law of England as to the criminal responsibility of the insane. The points affirmed by the Rules that must be noted here are the propositions that knowledge of the nature and quality of the particular criminal act, at the time of its commission, is the test of criminal responsibility, and that delusion is a valid exculpatory plea, when, and only when, the fancies of the insane person, if they had been facts, would have been so. The Rules in Macnaughton's case are open to serious criticism. They ignore, at least on a literal interpretation, those forms of mental disease which may, for the present purpose, be roughly grouped under the heading "moral insanity," and in which the moral faculties are more obviously deranged than the mental—the affections and the will, rather than the reason, being apparently disordered. The test propounded with reference to delusions has also been strenuously attacked by medical writers, and especially by Dr Maudsley in his work on *Responsibility in Mental Disease*, on the ground that it first assumes a man to have a delusion in regard to a particular subject, and then expects and requires him to reason sanely upon it. It may be pointed out, however, that in thus localizing the range of the immunity which insane delusion confers, the criminal law is merely following the course which, *mutatis mutandis*, the civil law has with general acceptance adopted in questions as to the contractual and testamentary capacity of the insane.

Criminals.

Macnaughton's case.

The Rules in Macnaughton's case have, as regards moral insanity, undergone considerable modification. Soon after they were laid down, Sir (then Mr) James Fitz-James Stephen, in an article in the *Juridical Papers* (vol. i. p. 67) on the policy of maintaining the existing law as to the criminal responsibility of the insane, foreshadowed the view which he subsequently propounded in his *History of the Criminal Law* (vol. ii. p. 163), that no man who was deprived by mental disease of the power of passing a fairly rational judgment on the moral character of an act could be said to "know" its nature and quality within the meaning of the Rules; and it has in recent years been found possible in practice so to manipulate the test of criminal responsibility which they prescribed as to afford protection to the accused in the by no means infrequent cases of insanity which in its literal interpretation it would leave without excuse.

In Scotland the Rules in Macnaughton's case are recognized, but, as in England, there is a tendency among judges to adopt a generous construction of them. Mental unsoundness insufficient to bar trial, or to exempt from punishment, may still, it is said, be present in a degree which is regarded as reducing the offence from a higher to a lower category,—a doctrine first practically applied in Scotland, it is believed, in 1867 by Lord Deas; and the

fact that a prisoner is of weak or ill-regulated mind is often urged with success as a plea in mitigation of punishment. The Indian Penal Code (Act 45 of 1860, § 84) expressly adopts the English test of criminal responsibility, but the qualifications noted in the case of Scotland have received some measure of judicial acceptance (see Mayne, *Crim. Law Ind.* pp. 368–384; Nelson, *Ind. Pen. Code*, pp. 79–89). The Rules in Macnaughton's case have also been adopted in substance in those colonies which have codified the criminal law. The following typical references may be given: 55 and 56 Vict. (Can.) c. 29, § 11; 57 Vict. (N.Z.), No. 56 of 1893, § 23; No. 101 of 1888 (St Lucia), § 50; No. 5 of 1876 (Gold Coast), § 49 (*b*). The Rules were rapidly reproduced in the United States, but the modern trend of American judicial opinion is adverse to them (see Clevenger, *Med. Jur. of Ins.* p. 125). On the Continent moral insanity and irresistible impulse are freely recognized as exculpatory pleas (see the French *Code Penal*, § 64; Belgian *Code Penal*, § 71; German *Penal Code*, § 51).

Not only is insanity at the time of the commission of an offence a valid exculpatory plea, but supervening insanity stays the action of the criminal law at every stage from arrest up to punishment. High treason was formerly an exception, but the statute making it so (33 Hen. VIII. c. 20) was repealed in the time of Philip and Mary. The Home Secretary has power, under the Criminal Lunatics Act, 1884, to order by warrant the removal of a prisoner, certified to be insane, to a lunatic asylum, before[1] trial or after trial, whether under sentence of death or not. Prisoners dealt with under these provisions are styled "Secretary of State's lunatics." On the other hand, a prisoner who on arraignment appears, or is found by the jury to be unfit to plead, or who is found "guilty but insane" at the time of committing the offence—a verdict substituted by the Trial of Lunatics Act, 1883, for the old verdict of "acquitted on the ground of insanity," in the hope that the formal conviction recorded in the new finding might have a deterrent effect on the mentally unstable—is committed to a criminal lunatic asylum by the order of the judge trying the case, to be detained there "during the Sovereign's pleasure." Lunatics of this class are called "Sovereign's pleasure lunatics." There was no doubt at common law as to the power of the courts to order the detention of criminal lunatics in safe custody, but prior to 1800 the practice was varying and uncertain. On the acquittal of Hadfield, however, in that year for the attempted murder of George III., a question arose as to the provision which was to be made for his detention, and the Criminal Lunatics Act, 1800, part of which is still in force, was passed to affirm the law on the subject.

The Criminal Lunatics Act contains provisions similar to those of the Lunacy Act, 1890, as to the discharge (conditional or absolute) and transfer of criminal lunatics and the detention of persons becoming pauper lunatics. The expenses of the maintenance of criminal lunatics are defrayed out of moneys provided by Parliament (Crim. Luns. Act, 1884, and Hansard, 3rd series, vol. ccxc. p. 75; 139 Com. Jo., pp. 336, 340, 344). The Lunatics' Removal (India) Act, 1851, provides for the removal to a criminal lunatic asylum in Great Britain of persons found guilty of crimes and offences in India, and acquitted on the ground of insanity. Similar provisions with regard to colonial criminal lunatics are contained in the Colonial Prisoners' Removal Act, 1884; and the policy of this statute has been followed by No. 5 of 1894 (New South Wales), and Ordin. No. 2 of 1895 (Falkland Islands). Indian law (see Act 5 of 1898, §§ 464–475) and the laws of the colonies (the Cape Act No. 1 of 1897 is a typical example) as to the trial of lunatics are similar to the English. In Scotland all the criminal lunatics, except those who may have been removed to the ordinary asylums or have been discharged, are confined in the Criminal Asylum established at Perth in connexion with H.M.'s General Prison, and regulated by special Acts (23 and 24 Vict. c. 105, and 40 and 41 Vict. c. 53). Provision, similar to the English, has been made for prisoners found insane as a bar to trial, or acquitted on the ground of insanity, or becoming insane in confinement. In New York and Michigan there are criminal lunatic asylums. Elsewhere insane criminals are apparently detained in state asylums, hospitals, or prisons. The statutory rules as to the maintenance of criminal lunatic asylums, the treatment of the criminal insane, and the plea of insanity in criminal courts in America, closely resemble English practice. The only special point in Continental law calling for notice is the system by which official experts report for the guidance of the tribunals on questions of alleged criminal irresponsibility (see, *e.g.*, the German *Code of Penal Procedure*, § 293, and cp. § 81).

Civil capacity.

The law as to the civil capacity of the insane was for some time influenced in Great Britain by the view propounded by Lord Brougham in 1848 in the case of *Waring* v. *Waring*, and by Sir J. P. Wilde in a later case, raising the question of the validity of a marriage, that, as the mind is one and indivisible, the least disorder of its faculties was fatal to civil capacity. In the leading case of *Banks* v. *Goodfellow* in 1870, the Court of Queen's Bench, in an elaborate judgment delivered by Chief Justice Cockburn, disapproved of this doctrine, and in effect laid down the principle that the question of capacity must be considered with strict reference to the act which has to be or has been done. Thus a certain degree of unsoundness of mind is not now, in the absence of undue influence, a bar to the formation of a valid marriage, if the party whose capacity is in question knew at the time of the marriage the nature of the engagement entered into (but see 51 Geo. III. c. 37 as to the marriage of lunatics so found by inquisition). Again, a man whose mind is affected may make a valid will, if he possesses at the time of executing it a memory sufficiently active to recall the nature and extent of his property, the persons who have claims upon his bounty, and a judgment and will sufficiently free from the influence of morbid ideas or external control to determine the relative strength of those claims. So far has this rule been carried, that in 1893 probate was granted of the will of a lady who was a Chancery lunatic at the date of its execution, and died without the inquisition having been superseded. It is also now settled that the simple contract of a lunatic is voidable and not void, and is binding upon him, unless he can show that at the time of making it he was, to the knowledge of the other party, so insane as not to know what he was about. The test established by *Banks* v. *Goodfellow* is applied also in a number of minor points in which civil capacity comes into question, *e.g.*, competency of the insane as witnesses. The law implies on the part of a lunatic, whether so found or not, an obligation to pay a reasonable price for "necessaries" supplied to him; and the term "necessaries" means goods suitable to his condition in life and to his actual require-

[1] It has sometimes been stated in recent years that this power, which ought clearly, in the interests alike of prisoners and of the public, to be exercised with caution, is in fact exerted in an unduly large number of cases. The following figures, taken from the respective volumes of the *Criminal Judicial Statistics*, show the number of criminal lunatics certified insane before trial. In 1884–85, out of a total of 938 criminal lunatics, 169 were so certified; in 1885–86, 149 out of 890; in 1889–90, 108 out of 926; in 1890–91, 95 out of 900; in 1894, 78 out of 738; in 1895, 84 out of 757; in 1896, 88 out of 769; in 1897, 85 out of 764; in 1898, 17 out of 209.

ments at the time of sale and delivery (Sale of Goods Act, 1893).

The question of the liability of an insane person for tort appears still to be undecided (see Pollock on *Torts*, 5th ed. p. 51; Clerk and Lindsell on *Torts*, 2nd ed. pp. 39, 40; *Law Quart. Rev.* vol. xiii. p. 325). Supervening insanity is no bar to proceedings by or against a lunatic husband or wife for divorce or separation for previous matrimonial offences. It does not avoid a marriage nor constitute *per se* a ground either for divorce or for judicial separation. But cruelty does not cease to be a cause of suit if it proceeds from disorderly affections or want of moral control falling short of positive insanity; and possibly even cruelty springing from intermittent or recurrent insanity might be held a ground for judicial separation, since in such case the party offended against cannot obtain protection by securing the permanent confinement of the offending spouse. Whether insanity at the time when an alleged matrimonial offence was committed is a bar to a suit for divorce or separation is an open question; and in any event, in order that it may be so, the insanity must be of such a character as to have prevented the insane party from knowing the nature and consequences of the act at the time of its commission. The laws of Scotland, Ireland, India (see, *e.g.*, Act 9 of 1872, § 12), the colonies, and the United States, are substantially identical with English law on the subject of the civil capacity of the insane. The German Civil Code (§ 1569) recognizes the lunacy of a spouse as a ground for divorce, but only where the malady continues during at least three years of the union, and has reached such a pitch that intellectual intercourse between the spouses is impossible, and that every prospect of a restoration of such association is excluded. If one of the spouses obtains a divorce on the ground of the lunacy of the other the former has to allow alimony, just as a husband declared to be the sole guilty party in a divorce suit would have to do (§§ 1585, 1578).

Jurisdiction.

In order to effect a change in the status of persons alleged to be of unsound mind, and to bring their persons and property under control, the aid of the jurisdiction in lunacy must be invoked. Under the unrepealed statute *De Prœrogativâ Regis* (17 Edw. II. cc. 9 and 10) the care and custody of lunatics belong to the Crown. But the Crown has, at least since the 16th century, exercised this branch of the prerogative by delegates, and principally through the Lord Chancellor—not as head of the Court of Chancery, but as the representative and delegate of the sovereign. Under the Lunacy Acts, 1890 and 1891, the jurisdiction in lunacy is exercised first by the Lord Chancellor and such of the Lords Justices and other judges as may be invested with it by the sign-manual; and, secondly, by the two Masters in lunacy, appointed by the Lord Chancellor from members of the bar of at least ten years' standing, whose duties include the holding of inquisitions and summary inquiries, and the making of most of the consequential orders dealing with the persons and estates of lunatics. County court judges may also exercise a limited jurisdiction in lunacy, in the case of lunatics as to whom a reception order has been made, if their entire property is under £200 in value, and no relative or friend is willing to undertake the management of it; in partnership cases where the assets do not exceed £500; and upon application by the guardians of any union for payment of expenses incurred by them in relation to any lunatic.

Persons of unsound mind are brought under the jurisdiction in lunacy either by an inquisition *de lunatico inquirendo*, or, in certain cases which will be adverted to below, by proceedings instituted under § 116 of the Lunacy Act, 1890, which is now the great practice section in the Lunacy Office. Prior to 1853 a special commission was issued to the Masters in each alleged case of lunacy. But by the Lunacy Regulation Act of that year a general commission was directed to the Masters, empowering them to proceed in each case in which the Lord Chancellor by order required an inquisition to be held. This procedure is still in force. A special commission would now be issued only where both Masters were personally interested in the subject of the inquiry, or for some other similar reason. An inquisition is ordered by the judge in lunacy (a term which does not, for this purpose, at present include the Masters, although this is one of the points in regard to which a change in the law is (1901) contemplated) on the petition generally of a near relative of the alleged lunatic. The inquiry is held before one of the Masters, and a jury may be summoned if the alleged lunatic, being within the jurisdiction, demands it, unless the judge is satisfied that he is not competent to form and express such a wish; and even in that case the Master has power to direct trial by jury if he thinks fit on consideration of the evidence. Where the alleged lunatic is not within the jurisdiction the trial must be by jury; and the judge in lunacy may direct this mode of trial to be adopted in any case whatever.

A few points of general interest in connexion with inquisitions must be noted. In practice thirty-four jurors are summoned by the sheriff, and not more than twenty-four are empannelled. Twelve at least must concur in the verdict. Counsel for the petitioner ought to act in the judicial spirit expected from counsel for the prosecution in criminal cases. The issue to be determined on an inquisition is "whether or not the alleged lunatic is at the time of the inquisition of unsound mind, and incapable of managing himself and his affairs" (a special verdict may, however, be found that the lunatic is capable of managing himself, although not his affairs, and that he is not dangerous to others); and without the direction of the person holding the inquisition, no evidence as to the lunatic's conduct at any time being more than two years before the inquisition is to be receivable. This limitation, both of the issue and of the evidence, was imposed with a view to preventing the recurrence of such cases as that of Mr Windham in 1861–62, when the inquiry ranged over the whole life of an alleged lunatic, forty-eight witnesses being examined on behalf of the relations, and ninety-one on behalf of the respondents, while the hearing lasted for thirty-four days. For the purpose of assisting the Master or jury in arriving at a decision, provision is made for the personal examination of the alleged lunatic by them on oath or otherwise, and either in open court or in private, as may be directed. The proceedings on inquisition are open to the public. When a person has been found lunatic by inquisition he becomes subject to the jurisdiction in lunacy, and remains so (unless he succeeds in setting aside the verdict by a "traverse"—a proceeding which ultimately comes before and is determined by the King's Bench Division in London, or at the assizes, according to circumstances) until his recovery, when the inquisition may be put an end to by a procedure technically known as "supersedeas," or by his death. The results of the inquisition are worked out in the Lunacy Office. The control of the estate, and, except where he was found incapable of managing his property only, of the person of the lunatic is entrusted to committees of the estate and person, who are appointed by and accountable to the Master in Lunacy, and whose legal position corresponds roughly with that of the tutors and curators of the civil law. The committee of the estate in particular exercises over the property of the lunatic, with

the sanction or by the order of the Master, very wide powers of management and administration, including the raising of money by sale, charge, or otherwise, to pay the lunatic's debts, or provide for his past or future maintenance, charges for permanent improvements, the sale of any property belonging to the lunatic, the execution of powers vested in him, and the performance of contracts relating to property.

The alternative method of bringing a person of unsound mind under lunacy jurisdiction was created by § 116 of the Lunacy Act, 1890. The effect of that section briefly is to enable the Master, on a summons being taken out in his chambers and heard before him, to apply the powers of management and administration summarized in the last preceding paragraph, without any inquisition, to the following classes of cases: lunatics not so found by inquisition, for the protection or administration of whose property any order was made under earlier Acts; every person lawfully detained, within the jurisdiction of the English courts, as a lunatic, though not so found by inquisition; persons not coming within the foregoing categories, who are "through mental infirmity arising from disease or age" incapable of managing their affairs; persons of unsound mind whose property does not exceed £2000 in value, or does not yield an annual income of more than £100; and criminal lunatics continuing insane and under confinement. The effect of the introduction of this simple summary procedure on the number of inquisitions will be apparent from the following figures, which are taken from the *Civil Judicial Statistics*. The annual average of inquisitions executed was, from 1858 to 1862, 64; from 1863 to 1867, 75; from 1868 to 1872, 86; from 1873 to 1877, 116; from 1878 to 1882, 112; from 1883 to 1887, 93; from 1888 to 1892, 80; from 1894 to 1898, 41·0. No annual average of the proceedings under § 116 has yet been taken. But in 1895 there were subsisting 945 cases under the section; in 1896, 1274; in 1897, 1323; in 1898, 1440. During 1897 orders for administration and management under the section are stated to have been made in 327 cases, while in the same year only 42 inquiries were held. At the end of 1897 the number of subsisting cases under inquisition was 1016.

In Scotland the insane are brought under the jurisdiction in lunacy by alternative methods, similar to the English inquisition and summary procedure, viz., "cognition," the trial taking place before the Lord President of the Court of Session or any judge of that court to whom he may remit it, and a jury of twelve—see 31 and 32 Vict. c. 100, and Act of Sederunt of 3rd December 1868—and an application to the Junior Lord Ordinary of the Court of Session, or (43 and 44 Vict. c. 4, § 4) to the Sheriff Court, when the estate in question does not exceed £100 a year, for the appointment of a *curator bonis* or judicial factor.

The powers of the Lord Chancellor of Ireland with regard to lunatics are generally similar to those of the English Chancellor (see 34 Vict. c. 22 and Colles on *The Lunacy Regulations* (*Ireland*) *Act*).

The main feature of the French system is the provision made by the Civil Code (Arts. 489–512) for the interdiction of an insane person by the Tribunal of First Instance, with a right of appeal to the Court of Appeal, after a preliminary inquiry and a report by a family council (Arts. 407, 408), consisting of six blood relatives in as near a degree of relationship to the lunatic as possible, or, in default of such relatives, of six relatives by marriage. The family council is presided over by the *Juge de Paix* of the district in which the lunatic is domiciled. There are provisions, it may be noted, in Scots law for the interdiction of lunatics, either voluntarily or judicially (see Bell's *Principles*, § 2123). The German Civil Code provides for insane persons being made subject to guardianship (*vormundung*), on conditions similar to those of Scots and French law (see Civil Code, §§ 6, 104, 1896, 1906, 645–679). In the United States the fundamental procedure in an inquisition is conducted on practically the same lines as in England.

Asylum administration in England is now regulated by the Lunacy Acts, 1890 and 1891. Receptacles for the insane are divisible into the following classes: (i.) Institutions for lunatics, including asylums, registered hospitals, and licensed houses. The asylums are provided by counties or boroughs, or by union of counties or boroughs. Registered hospitals are hospitals holding certificates of registration from the Commissioners in Lunacy, where lunatics are received and supported wholly or partially by voluntary contributions or charitable bequests, or by applying the excess of the payments of some patients towards the maintenance of others. Licensed houses are houses licensed by the Commissioners, or, beyond their immediate jurisdiction, by justices; (ii.) Workhouses—see article POOR LAW; (iii.) Houses in which patients are boarded out; (iv.) Private houses (unlicensed) in which not more than a single patient may be received. A person, not being a pauper or a lunatic so found by inquisition, cannot, in ordinary cases, be received and detained as a lunatic in any institution for the insane, except under a "reception order" made by a county court judge, or stipendiary magistrate, or specially appointed justice of the peace. The order is made on a petition presented by a relative or friend of the alleged lunatic, and supported by two medical certificates, and after a private hearing by the judicial authority. The detention of a lunatic is, however, justifiable at common law, if necessary for his safety or that of others; and the Lunacy Act, 1890, borrowing from the lunacy law of Scotland, provides for the reception of a lunatic not a pauper into an asylum, where it is expedient for his welfare or the public safety that he should be confined without delay, upon an "urgency order," made if possible by a near relative, and accompanied by one medical certificate. The urgency order only justifies detention for seven days (the curtailment of this period to four days is proposed), and before the expiration of that period the ordinary procedure must be followed. "Summary reception orders" may be made by justices otherwise than on petition. There are four classes of cases in which such orders may be made, viz.: (i.) lunatics (not paupers and not wandering at large) who are not under proper care and control, or are cruelly treated or neglected; (ii.) resident pauper lunatics; (iii.) lunatics, whether pauper or not, wandering at large; (iv.) lunatics in workhouses. (As to pauper lunatics generally, see article POOR LAW.) A lunatic may also be received into an institution under an order by the Commissioners in Lunacy; and a lunatic so found by inquisition under an order signed by the committee of his person.

Asylum administration.

The chief features of English asylum administration requiring notice are these. Mechanical restraint is to be applied only when necessary for surgical or medical purposes, or in order to prevent the lunatic from injuring himself or others. The privacy of the correspondence of lunatics with the Lord Chancellor, the Commissioners in Lunacy, &c., is secured. Provision is made for regular visits to patients by their relatives and friends. The employment of males for the custody of females is, except on occasions of urgency, prohibited. Pauper lunatics may be boarded out with relatives and friends. Elaborate provision is made for the official visitation of every class of receptacle for the insane. The duties of visitation are divided between the Commissioners in Lunacy, the

Chancery Visitors, and various other visitors and visiting committees. There are ten Commissioners in Lunacy—four unpaid and six paid, three of the latter being barristers of not less than five years' standing at the date of appointment, and three medical. The Commissioners in Lunacy, who are appointed by the Lord Chancellor, visit every class of lunatics except persons so found by inquisition. These are visited by the Chancery Visitors. There are three Chancery Visitors, two medical and one legal (a barrister of at least five years' standing at the date of his appointment), who are appointed and removable by the Lord Chancellor. The Chancery Visitors (together with the Master in Lunacy) form a Board, and have offices in the Royal Courts of Justice. In addition to these two classes of visitors, every asylum has a Visiting Committee of not less than seven members, appointed by the local authority; and the justices of every county and quarter-sessions borough not within the immediate jurisdiction of the Commissioners in Lunacy annually appoint three or more of their number as visitors of licensed houses.

Provision is made for the discharge of lunatics from asylums, &c., on recovery, or by *habeas corpus*, or by the various visiting authorities. Any person who considers himself to have been unjustly detained is entitled on discharge to obtain, free of expense, from the secretary to the Lunacy Commissioners a copy of the documents under which he was confined.

The Irish and Scots asylum systems present no feature sufficiently different from the English to require separate notice, except that in Scotland "boarding out" is a regular, and not merely an incidental part of asylum administration. The "boarding out" principle has, however, received its most extended and most successful application in the Gheel colony. In the French (see laws of 30th June 1838 and 18th December 1839) and German (see *Journal of Comparative Legislation*, N.S. vol. i. at pp. 271, 272) asylum systems the main features of English administration are also reproduced. In America the different States of the Union have each their own lunacy legislation. The Government of the United States provides only for the insane of the army and navy, and for those residing in the District of Columbia. The various laws as to the reception, &c., of the insane into asylums closely resemble English procedure. But in several States the verdict of a jury finding lunacy is a necessary preliminary to the commitment of private patients.

HOSPITAL TREATMENT.

The era of real hospitals for the insane properly belongs to the 19th century. There had been established here and there in different parts of the world, it is true, certain asylums or places of restraint before the beginning of the 19th century. We find mention in history of such a place established by monks at Jerusalem in the latter part of the 5th century. There is evidence that even earlier than this in Egypt and Greece the insane were treated as individuals suffering from disease. Egyptian priests employed not only music and the beautiful in nature and art as remedial agents in insanity, but recreation and occupation as well. A Greek physician protested against mechanical restraint in the care of the insane, and advocated kindly treatment, the use of music, and of some sorts of manual labour. But these ancient beneficent teachings were lost sight of during succeeding centuries. The prevailing idea of the pathology of insanity in Europe during the Middle Ages was that of demoniacal possession. The insane were not sick, but possessed of devils, and these devils were only to be exorcised by moral or spiritual agencies. Mediæval therapeutics in insanity adapted itself to the etiology indicated. Torture and the cruellest forms of punishment were employed. The insane were regarded with abhorrence, and were frequently cast into chains and dungeons. Milder forms of mental disease were treated by other spiritual means—such as pilgrimages to the shrines of certain saints who were reputed to have particular skill and success in the exorcism of evil spirits. The shrine of St Dymphna at Gheel, in Belgium, was one of these, and seems to have originated in the 7th century, a shrine so famed that lunatics from all over Europe were brought thither for miraculous healing. The little town became a resort for hundreds of insane persons, and as long ago as the 17th century acquired the reputation, which still exists to this day, of a unique colony for the insane. At the present time the village of Gheel and its adjacent farming hamlets (with a population of some 13,000 souls) provides homes, board, and care for nearly 2000 insane persons under medical and government supervision. Numerous other shrines and holy wells in various parts of Europe were resorted to by the mentally afflicted—such as Glen-na-Galt in Ireland, the well of St Winifred, St Nun's Pool, St Fillans, &c. At St Nun's the treatment consisted of plunging the patient backwards into the water and dragging him to and fro until mental excitement abated. Not only throughout the Middle Ages, but far down into the 17th century, demonology and witchcraft were regarded as the chief causes of insanity. And the insane were frequently tortured, scourged, and even burned to death.

Until as late as the middle of the 18th century, mildly insane persons were cared for at shrines, or wandered homeless about the country. Such as were deemed a menace to the community were sent to ordinary prisons, or chained in dungeons. Thus large numbers of lunatics accumulated in the prisons, and slowly there grew up a sort of distinction between them and criminals, which at length resulted in a separation of the two classes. In time many of the insane were sent to cloisters and monasteries, especially after these began to be abandoned by their former occupants. Thus "Bedlam" (the present Bethlehem Royal Hospital) was originally founded in 1247 as a priory for the brethren and sisters of the Order of the Star of Bethlehem. It is not known exactly when lunatics were first received into Bedlam, but some were there in 1403. Bedlam was rebuilt as an asylum for the insane in 1676. In 1815 a committee of the House of Commons, upon investigation, found it in a disgraceful condition, the medical treatment being of the most antiquated sort, and actual inhumanity practised upon the patients. Similarly the Charenton Asylum, just outside Paris, near the park of Vincennes, was an old monastery which had been given over to the insane. Numerous like instances could be cited, but the interesting point to be borne in mind is, that with a general tendency to improvement in the condition of imbeciles upon public charge, idiots

and insane persons came gradually to be separated from criminals and other paupers, and to be segregated. The process of segregation was, however, very slow. Even after it had been accomplished in the larger centres of civilization, the condition of these unfortunates in provincial districts remained the same. Furthermore, the transfer to asylums provided especially for them was not followed by any immediate improvement in the patients. The accounts of the state of the insane in various countries during the latter part of the 18th century and the beginning of the 19th are shocking to read.

Twenty-five years after Pinel had, in 1792, struck the chains from the lunatics huddled in the Salpêtrière and Bicêtre of Paris, and called upon the world to realize the horrible injustice done to this wretched and suffering class of humanity, a pupil of Pinel, Esquirol, wrote of the insane in France and all Europe, "These unfortunate people are treated worse than criminals, reduced to a condition worse than that of animals. I have seen them naked, covered with rags, and having only straw to protect them against the cold moisture and the hard stones they lie upon; deprived of air, of water to quench thirst, and all the necessaries of life; given up to mere gaolers and left to their surveillance. I have seen them in their narrow and filthy cells, without light and air, fastened with chains in these dens in which one would not keep wild beasts. This I have seen in France, and *the insane are everywhere in Europe treated in the same way.*" It was not until 1838 that the insane in France were all transferred from small houses of detention, workhouses, and prisons to asylums specially constructed for this purpose.

In Belgium, in the Middle Ages, the public executioner was ordered to expel from the towns, by flogging, the poor lunatics who were wandering about the streets. In 1804 the Code Napoleon "punished those who allowed the insane and mad criminals to run about free." In 1841 an investigation showed in Belgium thirty-seven establishments for the insane, only six of which were in good order. In fourteen of them chains and irons were still being used. In Germany, England, and America, in 1841, the condition of the insane was practically the same as in Belgium and France.

These facts show that no great advance in the humane and scientific care of the insane was made till towards the middle of the 19th century. Only then did the actual metamorphosis of asylums for detention into hospitals for treatment begin to take place. Hand in hand with this progress there has grown, and still is growing, a tendency to subdivision and specialization of hospitals for this purpose. There are now hospitals for the acutely insane, others for the chronic insane, asylums for the criminal insane, institutions for the feeble-minded and idiots, and colonies for epileptics. There are public institutions for the poor, and well-appointed private retreats and homes for the rich. All these are presided over by the best of medical authorities, supervised by unsalaried boards of trustees or managers, and carefully inspected by Government lunacy commissioners, or boards of charities—a contrast, indeed, to the gaols, shrines, holy wells, chains, tortures, monkish exorcisms, &c., of the past!

The statistics of insanity have nowadays been fairly well established. The ratio of insane to normal population is about 1 to 300 among civilized peoples. This proportion varies within narrow limits in different races and countries. It is probable that intemperance in the use of alcohol and drugs, the spread of venereal diseases, and the over-stimulation in many directions induced by modern social conditions, have caused an increase of insanity in the 19th as compared with past centuries. The amount of such increase is probably very small, but on superficial examination might seem to be large, owing to the accumulation of the chronic insane and the constant upbuilding of asylums in new communities. The imperfections of census-taking in the past must also be taken into account.

The modern hospital for the insane does credit to latter-day civilization. Physical restraint is no longer practised. The day of chains—even of wristlets, covered cribs, and strait-jackets—is past. Neat dormitories, cosy single rooms and sitting and dining rooms, please the eye. In the place of bare walls and floors and curtainless windows, we observe pictures, plants, rugs, birds, curtains, and in many asylums even the barred windows have been abolished. Some of the wards for milder patients have unlocked doors. Many patients are trusted alone about the grounds and on visits to neighbouring towns. An air of busy occupation is observed in sewing rooms, schools, shops, in the fields and gardens, employment contributing not only to economy in administration, but to improvement in mental and physical conditions. The general progress of medical science in all directions has been manifested in the department of psychiatry by improved methods of treatment, in the way of sleep-producing and alleviating drugs, dietetics, physical culture, hydrotherapy, and the like. There are few asylums now without pathological and clinical laboratories, in which work is going on with a view to unravelling some of the mysteries of disordered mind. While it is a far cry from the prisons and monasteries of the past to the modern hospital for the insane, it is still possible to trace a resemblance in many of our older asylums to their ancient prototypes, particularly in those asylums built upon the so-called corridor plan. It is always difficult to break away from established forms, and though each generation contributed something new, antecedent models were more or less adhered to. Progress in asylum architecture has hence advanced more slowly in countries where monasteries and cloisters abounded than in countries where fixed models did not exist. Architects have had a freer hand in America, Australia, and Germany, and even in Great Britain, than in the Catholic countries of Europe. At the present time Germany approaches nearest to an ideal standard of provision for the insane. The highest and best idea which has yet been attained is that of small hospitals for the acutely insane in all cities of more than 50,000 inhabitants, and of colonies for the chronic insane in the rural districts adjacent to centres of population.

The psychopathic hospital in the city gives easy and speedy access to persons taken suddenly ill with mental disease, aids in early diagnosis, places the patients within reach of the best specialists in all departments of medicine, and associated, as it should be, with a medical school or university, affords facilities not otherwise available for scientific research and for instruction in an important branch of medical learning. A feature of the psychopathic hospital should be the reception of patients for a reasonable period of time, as sufferers from disease, without the formality of legal commitment papers. Such papers are naturally required for the detention and restraint of the insane for long periods of time, but in the earlier stages they should be spared the stigma, delay, and complicated procedure of commitment for at least ten days or two weeks, since in that time many may convalesce or recover, and in this way escape the public record of their infirmities, unavoidable by present judicial procedures.

There should be associated with such hospitals for the acutely insane in our cities out-door departments or dispensaries, to which patients may be brought in still earlier stages of mental disorder, at a period when early diagnosis and preventive therapeutics may have their best opportunities to attain good results. In Germany a psychopathic hospital now exists in every university town, under the name of Psychiatrische Klinik. As far as the writer knows, there are no such institutions in Great Britain, France, or America.

Colonies for the chronic insane are established in the country, but in the neighbourhood of the cities having psychopathic hospitals, to receive the overflow of the latter when the acute stage has passed. The true colony is constructed on the principle of a farming hamlet, without barracks, corridored buildings, or pavilions. It is similar in most respects to any agricultural community. The question here is one of humane care and economical administration. Humane care includes medical supervision, agreeable home-life, recreation, and, above all things, regular manual and out-of-door occupation in garden, farm, and dairy, in the quarry, clay-pit, or well-ventilated shop. Employment for the patients is of immense remedial importance, and at the same time is of great value from the standpoint of economical administration. In the colony system the small cottage homes of the patients are grouped about the centres of industry. The workers in the farmstead live in small families about the farmstead group of buildings; the tillers of the soil adjacent to the fields, meadows, and gardens; the brickmakers, quarrymen, and artizans in still other cottages in the neighbourhood of the scenes of their activities. In addition to these groups of cottages, which constitute the majority of the buildings in the village, an infirmary for bedridden, excited, and crippled patients is required, and a small hospital for the sick. All the inhabitants of the colony are under medical supervision. A laboratory for scientific researches forms a highly important part of the equipment. The colony is not looked upon as a refuge for the incurable; it is still a hospital for the sick, where treatment is carried on under the most humane and most suitable conditions, and wherein the percentage of recoveries will be larger than in asylums and hospitals as now conducted. In respect of the establishment of colonies for the insane upon the plan outlined here, Germany has, as in the case of the psychopathic hospital, led the world. It has been less difficult for that country to set the example, because she had fewer of the conditions of the past to fight, fewer of the old-time models to contend against, and with her the progress of medical science and of methods of instruction in all departments of medicine has been more pronounced and rapid. As already stated, every university town in Germany has its psychopathic hospital, and in the matter of colonies for the insane many of the provinces have already established them. Among the colonies, that at Alt-Scherbitz, near Leipzig, is the oldest and most successful, and is pre-eminent in its close approach to the ideal village or colony system. Professor Kraeplin, of Heidelberg (*Psychiatrie*, 6th edition, 1899), states that the effort is made everywhere in Germany to give the exterior of asylums, by segregation of the patients in separate home-like villas, rather the appearance of hamlets for working-people than prisons for the insane, and says, further, that the whole question of the care of the insane has found solution in the colony system, which is the best and cheapest method of support. "I have myself," he writes, "had opportunity to see patients, who had lived for years in a large closed asylum, improve in the most extraordinary manner under the influence of the freer movement and more independent occupation of colony life."

There is no institution in England or America constructed on the village system, with the sole exception of the Craig Colony for Epileptics at Sonyea, where the colony scheme has been adopted by the State of New York, and is being carried out on a large and successful scale.

That the tendency nowadays, even outside of Germany, in the direction of the ideal standard of provision for the insane is a growing one, is manifested in all countries by a gradual disintegration of the former huge cloister-like abodes. More asylums are built on the pavilion plan, which is a step in the right direction. Many asylums have, as it were, thrown off detached cottages for the better care of certain patients. Some asylums have even established small agricultural colonies a few miles away from the parent plant, like a vine throwing out feelers. What is called the boarding-out system is an effort in a similar direction. Patients suffering from mild forms of insanity are boarded out in families in the country, either upon public or private charge. Gheel is an example of the boarding-out system practised on a large scale. But it is only a matter of time when the ideal system of psychopathic hospital and colony for the insane will be gradually adopted everywhere.

INSECTS.

IN the following supplementary article the order of treatment is similar to that adopted in the earlier volumes of this encyclopædia (9th edition).

1. *Number of Species.*—It is now considered that 2,000,000 is a moderate estimate of the species of insects actually existing. Some authorities consider this total to be too small, and extend the number to 10,000,000. Upwards of 300,000 species have been collected and described, and at present the number of named forms increases at the rate of about 8000 species per annum. The greater part by far of the insects existing in the world is still quite unknown to science. Many of the species are in process of extinction, owing to the extensive changes that are taking place in the natural conditions of the world by the extension of human population and of cultivation, and by the destruction of forests; hence it is probable that a considerable proportion of the species at present existing will disappear from the face of the earth before we have discovered or preserved any specimens of them.

2. *Antiquity.*—A large number of species of fossil insects have been recently discovered in the Carboniferous measures of Commentry, in France. They have been described by the late M. Charles Brongniart, and indicate a much greater richness and variety of insect life in Palæozoic times than was formerly believed to exist. On the other hand, no greater extension of the absolute antiquity of insects has been found. It is true that a Silurian fossil—*Palæoblattina douvillei*—has been described as an insect relic, but this identification is probably erroneous. Some of the Carboniferous insects were of gigantic size, one form—apparently allied to the Odonata, or dragon-flies, of our own epoch—measuring more than 2 feet across the expanded wings. Blattidæ, or cockroaches, existed abundantly in Carboniferous times, and were apparently not very different from those now extant. The insects of the Palæozoic epoch have been combined in a great group, called Palæodictyoptera by Scudder. This classification is apparently chiefly justified by the fact that many Palæozoic insects cannot be satisfactorily placed in the same divisions as existing insects.

3. *Geographical Distribution.*—Recent discoveries induce the belief that islands, even when remote from continents, possess a greater number of species peculiar to them than was formerly supposed. More extensive investigation of island-life is, however, urgently needed.

4. *Duration of Life.*—The flour-moth (*Ephestia kuhniella*) sometimes passes through five or six generations in a single year. Although one of the characteristics of insects is the brevity of their adult lives, a considerable number of exceptions to the general rule have been discovered. These exceptions may be briefly summarized as follows: (1) Certain larvæ, provided with food that may be adequate in quantity but deficient in nutriment, may live and go on feeding for many years; (2) certain stages of the life that are naturally "resting stages" may be in exceptional cases prolonged, and that to a very great extent; in this case no food is taken, and the activity of the individual is almost *nil;* (3) the life of certain insects in the adult state may be much prolonged if celibacy be maintained; a female of *Cybister rœselii* (a large water-beetle) has lived five and a half years in the adult state in captivity. In addition to these abnormal cases, the life of certain insects is naturally more prolonged than usual. The females of some social insects have been known to live for many years. In *Cicada septendecim* the life of the larva extends over from thirteen to seventeen years. The eggs of locusts may remain for years in the ground before hatching; and there may thus arise the peculiar phenomenon of some species of insect appearing in vast numbers in a locality where it has not been seen for several years.

5. *Economic Entomology.*—The influence of insects on the prosperity of man, and practical work in connexion therewith, have attracted great attention, and there are now various countries in which experts are employed by the State to study this subject and give advice thereon. (See ECONOMIC ENTOMOLOGY, MOSQUITO, TSETSE FLY.)

J. B. Smith estimates that in New Jersey insects diminish the value of the crop annually to the extent of at least 20 or 25 per cent.; and Osborn considers that, in ordinary pasture, insects take a toll of about one-half the produce. As the multiplication of animals of this class is sometimes both great and rapid, it happens not infrequently that crops are totally destroyed. Official statistics show that in the island of Cyprus more than 1300 tons of locusts' eggs were collected and destroyed in the year 1881. The regions that suffer most are lands in which cultivation is proceeding in proximity to large districts still in a wild state. Islands to which new forms of cultivated vegetation are introduced sometimes suffer severely. The undue multiplication of insects destructive to vegetation is, in lands in a state of nature, checked by other insects that feed on, or in, the injurious kinds. When foreign plants are introduced to a region it often happens that insects injurious to them are sooner or later found to be present, while the natural enemies of the destroyers may be totally absent. A remedy for this has been sought by introducing the beneficial insects into the region devastated, a proceeding that is sometimes followed by satisfactory results. The orange and lemon trees of California ten years ago were in immediate danger of total extermination owing to the attacks of *Icerya purchasi*, a scale-insect. *Vedalia cardinalis*, a lady-bird or beetle of the family Coccinellidæ, was brought from Australia to California, and checked the ravages of the Icerya in a most rapid and successful manner. The Coccidæ, or scale-insects, are amongst the most injurious; they are minute creatures, with extremely limited faculty of locomotion, that fix themselves on plants, and are endowed with great powers of multiplication. Aphidæ, or plant-lice, are allied to Coccidæ, and in some countries are very injurious. Many other kinds of insects have been found to be injurious, and the treatment necessary to counteract their ravages varies in accordance with the habits and nature of the ravagers. Countries in which cultivation has long been predominant do not as a rule suffer severely from insect depredations, a kind of fluctuating natural balance existing between depredators and their destroyers. Artificial forests (under which we include forests the natural conditions of which have been much interfered with) appear, however, to be everywhere liable to destruction.

Mosquitoes and Malaria.—Increase of knowledge as to the minute organisms that are the causes of certain diseases in man (and the fact that an extremely minute quantity of matter is adequate for the transference of germs) has led to the belief that various diseases may be disseminated by insects. In the case of malaria it is now established that it is conveyed by mosquitoes of the genus *Anopheles*, and that these insects are essential to its existence. The organism that gives rise to the symptoms of malaria exists in the blood, where it attacks the corpuscles, and may increase greatly in numbers. There are several forms of these parasites, and the generic name Hæmamœba is now applied to them. Ross calls the form that gives rise to quartan fever in man Hæmamœba malariæ. It was formerly supposed that malaria was communicated by infected water or air, but the parasite has now been found to live in the body of the Anopheles. When a mosquito bites a person it injects a minute quantity of its saliva into the wound, and the malarial parasite is thus introduced. The parasite multiplies in the blood, so that if the patient be again bitten and blood sucked from him by another mosquito the insect becomes thereafter an inoculatory agent. It would appear to be probable that negroes, who in many cases are themselves nearly immune to the pathological symptoms of malaria, serve to keep the mosquitoes supplied with the malarial organism. The parasite is taken into the alimentary canal of the mosquito, passes into the body cavity of the fly, and thence into the salivary glands, and undergoes an important part of its development in the insect. The mosquito is essential to the existence of the disease, because it is in the body of the fly that an important part of the series

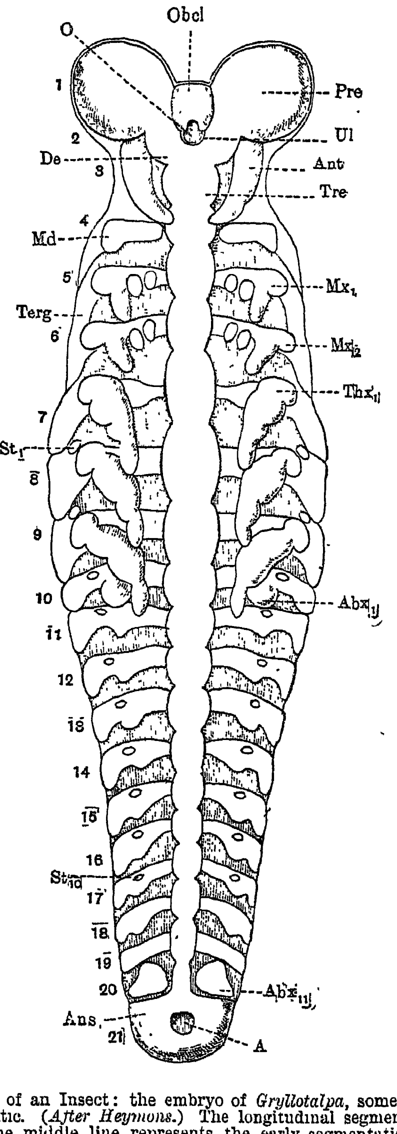
of life-changes of the parasite is passed through. (See also MOSQUITO and SPOROZOA.)

6. *Fertilization of Plants.*—Bombi, or bumble-bees, have been successfully introduced into New Zealand, with the result that clover produces plenty of seed there, and that seedlings of various other plants are much augmented. But in Australia the introduction has not been successful.

7. *Luminosity.*—This subject has received considerable attention, but is still a difficult one. In some of the light-giving forms the eggs have been found to be luminescent before any development takes place in them, it being thus proved that the property is not dependent on the existence of a special organ. The view that the light is due to phosphorus in any form has not been sustained. It is affirmed by Dubois that luminescence is due to the reactions of two special substances, luciferase and luciferine. In a luminous organ light is produced by the entry of hæmolymph, or blood containing luciferine, to the area containing luciferase. The light given by insects has been shown to be highly economical, and if a similar illuminating agent can be produced artificially it will be a great boon.

8. *Galls.*—A great variety of deformations and growths produced by insects and mites as well as by fungi has been described. They are in some cases very slight, and in others form remarkably large and definite structures. The whole are now included under the term Cecidia; a prefix gives the name of the organism to which the attacks are due, *e.g.*, Phytoptoccidia are the galls formed by Phytoptid mites. Simple galls are those that arise when only one member of a plant is involved; compound galls are the result of attacks on buds. Amongst the most remarkable galls recently discovered we may mention those found on Eucalyptus, Casuarina, and other trees and plants in Australia. They are remarkable for their variety, and are due to small scale-insects of the peculiar subfamily Brachyscelinæ. As regards the mode of production of galls, the most important distinction is between galls that result from the introduction of an egg, or other matter, into the interior of the plant, and those that are due to an agent acting externally, the gall in the latter case frequently growing in such a manner as ultimately to enclose its producers. The form and nature of the gall are the result of the powers of growth possessed by the plant. It has long been known, and is now generally recognized, that a gall can only be produced when the tissue of a plant is interfered with during, or prior to, the actual development of the tissue. Little more than this is known. The power that gall-producers possess of influencing by direct interference the growth of the cells of the plant that affords them the means of subsistence is an art that appears to be widely spread among animals, but is at the same time one of which we have little knowledge. The views of Adler as to the alternation of generations of numerous gall-flies have been fully confirmed, it having been ascertained by direct observation that the galls and the insects produced from them in one generation are entirely different from the next generation; and it has also been rendered certain that frequently one of the alternate generations is parthenogenetic, no males being produced. It is supposed that these remarkable phenomena have gradually been evoked by difference in the nutrition of the alternating generations. When two different generations are produced in one year on the same kind of tree it is clear the properties of the sap and tissues of the tree must be diverse so that the two generations are adapted to different conditions. In some cases the alternating generations are produced on different species of trees, and even on different parts of the two species.

9. *Anatomy—Morphology.*—Much work has been devoted to ascertaining the structure of the insect during the period of development in the egg. The addition of this embryological knowledge to the results yielded by study of the comparative anatomy of the perfect insect is enabling



Morphology of an Insect: the embryo of *Gryllotalpa*, somewhat diagrammatic. (*After Heymons.*) The longitudinal segmented band along the middle line represents the early segmentation of the nervous system and the subsequent median field of each sternite; the lateral transverse unshaded bands are the lateral fields of each segment; the shaded areas indicate the more internally placed mesoderm layer. The segments are numbered 1–21; 1–6 will form the head, 7–9 the thorax, 10–21 the abdomen. *A*, anus; Abx_1 Abx_{11}, appendage of 1st and of 11th abdominal segments; *Ans*, anal piece = telson or 12th abdominal segment; *Ant*, antenna; *De*, deuterencephalon; *Md*, mandible; Mx_1, first maxilla; Mx_2, second maxilla or labium; *O*, mouth; *Obcl*, rudimentary labrum and clypeus; *Pre*, protencephalon; St_1, St_{10}, stigmata 1 and 10; *Terg*, tergite; Thx_1, appendage of first thoracic segment; *Tre*, tritencephalon; *Ul*, a thickening at hinder margin of the mouth.

us to interpret the structure of the latter correctly, and to form an opinion as to what are the most important of the similarities and distinctions we observe. Our knowledge relates at present chiefly to the lower insects. The higher members of the class undergo at the penultimate stages of their life a metamorphosis so complete and rapid as to render the correct interpretation of their structures a matter of very great difficulty. (For details see § 10 below, under *Metamorphosis.*)

Segments.—One of the most constant features of insect structure is the segmentation (see Fig.). The segments are perceptible at a very early stage of the development

as a number of transverse bands arranged in a linear sequence. The first segmentation of the ventral plate—the minute part of the blastoderm that ultimately develops into the embryo—is not, however, very definite, and the segmentation does not make its appearance simultaneously throughout the whole length of the plate; the anterior parts are segmented before the posterior. In Orthoptera and Thysanura, as well as some others of the lower insects, it may be said that twenty-one of these divisions—not, however, all similar—may be distinguished, six of which subsequently enter into the formation of the head, three going to the thorax and twelve to the abdomen. In Hemiptera only eleven, and in Collembola only six, abdominal segments have been detected. The first and last of these twenty-one divisions are so different from the others that they can scarcely be considered true segments.

Head Segments.—In the adult insect the head is insignificant in size compared with the thorax or abdomen, but in the embryo it forms a much larger portion of the body than it does in the adult. Its composition has been the subject of prolonged difference of opinion. Formerly it was said that the head consisted of four divisions, viz., three segments and the procephalic or præ-oral lobes. It is now ascertained that the procephalic lobes consist of three divisions, so that the head may be said to be formed from six divisions. The first of these, according to the nomenclature of Heymons, is the mouth, or oral, piece; the second, the antennal segment; the third, the intercalary or præ-mandibular segment; while the fourth, fifth, and sixth are respectively the segments of the mandibles and of the first and second maxillæ. These six divisions of the head are diverse in kind, and subsequently undergo so much change that the part each of them takes in the formation of the head-capsule is not finally determined. The labrum and clypeus are developed as a single prolongation of the oral piece, not as a pair of appendages. The antennal segment apparently entirely disappears, with the exception of a pair of appendages it bears; these become the antennæ; it is possible that the original segment, or some part of it, may even become a portion of the actual antennæ. The intercalary segment has no appendages, or rudiments thereof, and probably subsequently entirely disappears. The appendages of the posterior three, or trophal, segments become the parts of the mouth. The appendages of the two maxillary segments arise as treble, instead of single, projections, thus differing from other appendages. From these facts it appears that the anterior three divisions of the head differ strongly from the posterior three, which greatly resemble thoracic segments; hence it has been thought possible that the anterior divisions may represent a primitive head, to which three segments and their leg-like appendages were subsequently added to form the head as it now exists. This is, however, very doubtful, and an entirely different inference is possible. In reference to the structure of the head-capsule in the imago, it appears that the clypeus and labrum represent, as already said, an unpaired median outgrowth of the oral piece; that immediately behind them comes the "frons," formed by the junction in the median line of the sides of the oral piece, but without suture there, because the junction takes place early and before any process of chitinous excretion occurs; that the "vertex" is formed by the tergites—or lateral growths—of the posterior three head segments, the mandibular segment contributing also the genæ.

Hypopharynx.—Great difference of opinion exists as to this structure, which is extremely different in the various kinds of insects; it may be briefly described as a fold forming the floor, or a part thereof, of the mouth. It has even been thought that it represents a distinct segment, or the pair of appendages of a distinct segment. Heymons considers that it represents the sternites of the three trophal segments, and that the "gula" is merely a secondary development. Folsom looks on the hypopharynx as a secondary development, but considers that some lateral parts in connexion with it represent an additional or seventh segment, which he calls superlingual, and considers as situate between the mandibular and first maxillary segments. The ganglia of the nervous system offer some important evidence as to the morphology of the head, and are alluded to below.

Thoracic Segments.—These are always three in number. The three pairs of legs appear very early as rudiments. Though the thoracic segments bear the wings, no trace of these appendages exists till the close of the embryonic life, nor even, in many cases, till much later. The thoracic segments, as seen in an early stage of the ventral plate, display in a well-marked manner the essential elements of the insect segment. These elements are, a central piece or sternite, and a lateral field on each side bearing the leg-rudiment. The external part of the lateral field subsequently grows up, and by coalescence with its fellow forms the tergite or dorsal part of the segment.

Abdominal Segments and Appendages.—We have already seen that in numerous lower insects the abdomen is formed from twelve divisions placed in linear fashion. Eleven of these may perhaps be considered as true segments, but the twelfth or terminal one is different, and is called by Heymons a telson; in it is placed the anal orifice, and the mass subsequently becomes the upper and lower laminæ anales. In Hemiptera this telson is absent, and the anal orifice is placed quite at the termination of the eleventh segment. Moreover, in this Order the abdomen shows at first a division into only nine segments and a terminal mass, which last subsequently becomes divided into two. The appendages of the abdomen are called cerci, styles, and gonapophyses. They differ much according to the kind of insect, and in the adult according to sex. Difference of opinion as to the nature of the abdominal appendages prevails. The cerci, when present, appear in the mature insect to be attached to the tenth segment, but according to Heymons they are really appendages of the eleventh segment, their connexion with the tenth being secondary and the result of considerable changes that take place in the terminal segments. It has still to be shown that any true cerci exist in the higher insects. In those insects in which a median terminal appendage exists between the two cerci this is considered to be a prolongation of the eleventh tergite. The styles, when present, are placed on the ninth segment, and in some Thysanura exist also on the eighth segment; their development takes place later in life than that of the cerci. The gonapophyses are the projections near the extremity of the body that surround the sexual orifices, and vary extremely according to the kind of insect. They have chiefly been studied in the female, and form the sting and ovipositor, organs peculiar to this sex. They are developed on the ventral surface of the body, and are six in number, one pair arising from the eighth ventral plate and two pairs from the ninth. This has been found to be the case in insects so widely different as Orthoptera and Aculeate Hymenoptera. The genital armature of the male is formed to a considerable extent by modifications of the segments themselves. The development of the armature has been little studied, and the question whether there may be present gonapophyses homologous with those of the female is open.

In the adult state no insect possesses more than six legs, and they are always attached to the thorax; in many Thysanura there are, however, processes on the abdomen that, as to their position, are similar to legs. In the embryos of many insects there are projections from the segments of the abdomen similar, to a considerable extent, to the rudimentary thoracic legs. The question whether these projections can be considered an indication of former polypody in insects has been raised. They do not long persist in the embryo, but disappear, and the area each one occupied becomes part of the sternite. In some embryos there is but a single pair of these rudiments (or vestiges) situate on the first abdominal segment, and in some cases they become invaginations of a glandular nature. Whether cerci, styles, and gonapophyses are developed from these rudiments has been much debated. It appears that it is possible to accept cerci and styles as modifications of the temporary pseudopods, but it is more difficult to believe that this is the case with the gonapophyses, for they apparently commence their development considerably later than cerci and styles and only after the apparently complete disappearance of the embryonic pseudopods. The fact that there are two pairs of gonapophyses on the ninth abdominal segment would be fatal to the view that they are in any way homologous with legs, were it not that there is some evidence that the division into two pairs is secondary and incomplete. The pseudopods that exist on the abdomen of numerous caterpillars may possibly arise from the embryonic pseudopods, but this also is far from being established.

Nervous System.—The nervous system is ectodermal in origin, and is developed and segmented to a large extent in connexion with the outer part of the body, so that it affords important evidence as to the segmentation thereof. The continuous layer of cells from which the nervous system is developed undergoes a segmentation analogous with that we have described as occurring in the ventral plate; there is thus formed a pair of contiguous ganglia for each segment of the body, but there is no ganglion for the telson. The ganglia become greatly changed in position during the later life, and it is usually said that there are only ten pairs of abdominal ganglia even in the embryo. In Orthoptera, Heymons has demonstrated the existence of eleven pairs, the terminal pair becoming, however, soon united with the tenth. The nervous system of the embryonic head exhibits three ganglionic masses, anterior to the thoracic ganglionic masses; these three masses subsequently amalgamate and form the sub-œsophageal ganglion, which supplies the trophal segments. In front of the three masses that will form the sub-œsophageal ganglion the mass of cells that is to form the nervous system is very large,

and projects on each side; this anterior, or præ-oral, mass consists of three lobes (the prot-, deut-, and tritencephalon of Viallanes and others), each of which may represent a segmental ganglion. They subsequently form the supra-œsophageal ganglion, or brain proper. Thus the evidence afforded by the great ventral chain of nerves supports the view that the number of divisions of the body in the lower insects is twenty, plus a terminal piece or telson. The telson and the anterior segment, or head-piece, at the other extremity exhibit considerable distinctions from the other segments. There are other ganglia in addition to those of the ventral chain, and Ch. Janet supposes that the ganglia of the sympathetic system indicate the existence of three other head-segments; the remains of the segments themselves are, in accordance with this view, to be sought in the stomodæum (to which we allude below). Folsom considers that there are seven sets of cephalic ganglia, and thus supports his view as to the composition of the head.

Alimentary Canal.—The anterior and posterior parts of the alimentary canal have for long been known to have their origin in ectoderm, and to be thus, as it were, parts of the exterior of the body; they are called respectively the stomodæum and proctodæum. The middle portion of the alimentary canal—the stomach or mesenteron—has until recently been considered to be endodermal. Heymons has shown that it is of secondary ectodermal origin in several insects, and his views have been confirmed, from study of other Orders, by various authorities. It appears, therefore, to be established that in the majority of insects the mesenteron is formed by cells from the stomodæum and proctodæum that subsequently unite, and not from endodermal rudiments in close proximity with these two parts, as Graber and others believed, and as is usually the case in other animals. Heymons has also found that in Lepisma the mesenteron arises in a different manner, and is of endodermal origin, being developed from the yolk-cells.

10. *Metamorphosis.*—A great deal of investigation has been devoted to this remarkable feature of insect life. The outer layer—or embryonic ectoderm—of an insect consists of a layer of cells forming a continuous structure; the orifices in it—mouth, spiracles, anus, and terminal portions of the genital ducts—being invaginations of the outer wall. This cellular layer is called the hypodermis; it is protected externally by a cuticle, a layer of matter it itself excretes, or in the excretion of which it plays, at any rate, an important part. The cuticle is a dead substance, and is composed in large part of chitin. The cuticle contrasts strongly in its nature with the hypodermis it protects. It is different in its details in different insects and in different stages of the life of the same insect. The "sclerites" that make up the skeleton of the insect (which skeleton, it should be remembered, is entirely external) are made up of this chitinous excretion. The growth of an insect is usually rapid, and as the cuticle does not share therein, it is from time to time cast off by moulting or ecdysis. Before a moult actually occurs the cuticle becomes separated from its connexion with the underlying hypodermis. Concomitant with this separation there is commencement of the formation of a new cuticle within the old one, so that when the latter is cast off the insect appears with a partly completed new cuticle. The new instar—or temporary form—is often very different from the old one, and this is the essential fact of metamorphosis. Metamorphosis is, from this point of view, the sum of the changes that take place under the cuticle of an insect between the ecdyses, which changes only become externally displayed when the cuticle is cast off. The hypodermis is the immediate agent in effecting the external changes.

The study of the physiology of ecdysis in its simpler forms has unfortunately been somewhat neglected, investigators having directed their attention chiefly to the cases that are most striking, such as the transformation of a maggot into a fly, or of a caterpillar into a butterfly. The changes have been found to be made up of two sets of processes: histolysis, by which the whole or part of a structure disappears; and histogenesis, or the formation of the new structure. By histolysis certain parts of the hypodermis are destroyed, while other portions of it develop into the new structures. The hypodermis is composed of parts of two different kinds, viz., (1) the larger part of the hypodermis that exists in the maggot or caterpillar and is dissolved at the metamorphosis; (2) parts that remain comparatively quiescent previously, and that grow and develop when the other parts degenerate. These centres of renovation are called imaginal discs or folds. The adult caterpillar may be described as a creature the hypodermis of which is studded with buds that expand and form the butterfly, while the parts around them degenerate. In some insects (*e.g.*, the maggots of the blowfly) the imaginal discs are to all appearance completely separated from the hypodermis, with which they are, however, really organically connected by strings or pedicels. This connexion was not at first recognized and the true nature of imaginal discs was not at first perceived, even by Weismann, to whom their discovery in Diptera is due. In other insects the imaginal discs are less completely disconnected from the superficies of the larval hypodermis, and may indeed be merely patches thereof. The number of imaginal discs in an individual is large, upwards of sixty having been discovered to take part in the formation of the outer body of a fly. With regard to the internal organs, we need only say that transformation occurs in an essentially similar manner, by means of a development from centres distributed in the various organs. The imaginal discs for the outer wall of the body, some of them, at any rate, include mesodermal rudiments (from which the muscles are developed) as well as hypodermis. The imaginal discs make their appearance (that is, have been first detected) at very different epochs in the life; their absolute origin has been but little investigated. Pratt has traced them in the sheep-tick to an early stage of the embryonic life.

Histolysis and Histogenesis.—The process of destruction of the larval tissues was first studied in the forms where metamorphosis is greatest and most abrupt, viz., in the Muscid Diptera. It was found that the tissues were attacked by phagocytic cells that became enlarged and carried away fragments of the tissue; the cells were subsequently identified as leucocytes, or blood-cells. Hence the opinion arose that histolysis is a process of phagocytosis. It has, however, since been found that in other kinds of insects the tissues degenerate and break down without the intervention of phagocytes. It has, moreover, been noticed that even in cases where phagocytosis exists a greater or less extent of degeneration of the tissue may be observed before phagocytosis occurs. This process can therefore only be looked on as a secondary one that hastens and perfects the destruction necessary to permit of the accompanying histogenesis. This view is confirmed by the fate of the phagocytic cells. These do not take a direct part in the formation of the new tissue, but it is believed merely yield their surplus acquisitions, becoming ordinary blood-cells or disappearing altogether. As to the nature of histogenesis, nothing more can be said than that it appears to be a phenomenon similar to embryonic growth, though limited to certain spots. Hence we are inclined to look on the imaginal discs as cellular areas that possess in a latent condition the powers of growth and development that exist in the embryo, powers that only become evident in certain special conditions of the organism. What the more essential of these conditions may be is a question on which very little light has been thrown, though it has been widely discussed.

Much consideration has been given to the nature of metamorphosis in insects, to its value to the creatures, and to the mode of its origin. Insect metamorphosis may be briefly described as phenomena of development characterized by abrupt changes of appearance and of structure, occurring during the period subsequent to embryonic development and antecedent to the reproductive state. It is, in short, a peculiar mode of growth and adolescence. The differences in appearance between the caterpillar and the butterfly, striking as they are to the eye, do not sufficiently represent the phenomena of metamorphosis to the intelligence. The changes that take place involve a revolution in the being, and may be summarized under three headings:—(1) The food-relations of the individual are profoundly changed, an entirely different set of mouth-organs appears, and the kind and quantity of the food taken is often radically different. (2) A wingless, sedentary creature is turned into a winged one with superlative powers of aërial movement. (3) An individual in which the reproductive organs and powers are functionally absent becomes one in which these structures and powers are the only reason for existence, for the great majority of insects die after a brief period of reproduction. These changes are in the higher insects so extreme that it is difficult to

imagine how they could be increased. In the case of the common drone-fly, the individual, from a sedentary maggot living in filth, without any relations of sex, and with only unimportant organs for the ingestion of its foul nutriment, changes to a creature of extreme alertness, with magnificent powers of flight, living on the products of the flowers it frequents, and endowed with highly complex sexual structures.

In connexion with the question whether metamorphosis has been gradually acquired we have to consider two aspects, viz., the bionomic nature of metamorphosis, and to what extent it existed in primitive insects. Bionomically, metamorphosis may be defined as the sum of adaptations that have gradually fitted the larva (caterpillar or maggot) for one kind of life, the fly for another. So that we may conclude that the factors of evolution would favour its development. With regard to its occurrence in primitive insects, our knowledge of the geological record is most imperfect, but so far as it goes it supports the conclusion that holometabolism (*i.e.*, extreme metamorphosis) is a comparatively recent phenomenon of insect life. None of the groups of existing Holometabola have been traced with certainty farther back than the Mesozoic epoch, and all the numerous Palæozoic insect-fossils seem to belong to forms that possessed only imperfect metamorphosis. The only doubt arises from the existence of insect remains, referred to the order Coleoptera, in the Silesian Culm of Steinkunzendorf. The oldest larva known, *Mormolucoides articulatus*, is from the New Red Sandstone of Connecticut; it belongs to the Sialidæ, one of the lowest forms of Holometabola. It is now, in fact, generally admitted that metamorphosis has been acquired comparatively recently, and Scudder in his review of the earliest fossil insects states that "their metamorphoses were simple and incomplete, the young leaving the egg with the form of the parent, but without wings, the assumption of which required no quiescent stage before maturity."

The Pupa.—A brief digression must be devoted to this peculiar instar. If we admit that the larva has, in the phylogeny of insects, gradually diverged from the imago, and if we recollect that in the ontogeny the larva has always to become the imago (and of course still does so) notwithstanding the increased difficulty of the transformation, we cannot but recognize that a period of helplessness in which the transformation may take place is to be expected. It is generally considered that this is sufficient as an explanation of the existence of the pupa. This, however, is not the case, because the greater part of the transformation precedes the disclosure of the pupa, which, as Miall remarks, is structurally little other "than the fly enclosed in a temporary skin." Moreover, in many insects with imperfect metamorphosis the change from larva or (as the later stage of the larva is called in these cases) nymph to imago is about as great as the corresponding change in the Holometabola, as the student will recognize if he recalls the histories of Ephemeridæ, Odonata, and male Coccidæ. But in none of these latter cases have the wings to be changed from a position inside the body to become external and actively functional organs. The difference between the nymph or false pupa and the true pupa is that in the latter a whole stadium is devoted to the perfecting of the wings and body-wall after the wings have become external organs; the stadium is one in which no food is or can be taken, however prolonged may be its existence. Amongst insects with imperfect metamorphosis the nearest approximations to the true pupa of the Holometabola are to be found in the subimago of Ephemeridæ and in the quiescent or resting stages of Thysanoptera, Aleurodidæ, and Coccidæ. A much more thorough appreciation than we yet possess of the phenomena in these cases is necessary in order completely to demonstrate the special characteristics of the holometabolous transformation. But even at present we can correctly state that the true pupa is invariably connected with the transference of the wings from the interior to the exterior of the body. It cannot but suggest itself that this transference was induced by some peculiarity as to formation of cuticle, causing the growth of the wings to be directed inwards instead of outwards. We may remark that the flea possesses no wings, but is understood to possess a true pupa. This is a most remarkable case, but unfortunately very little information exists as to the details of metamorphosis in this group.

It has been incidentally remarked that the phenomena of holometabolism are connected with the development of wings inside the body (except in the case of the flea, where there are no wings in the perfect insect). The term Endopterygota has been proposed for those insects in which the early stages of development of the wing occur inside the body, and the term Exopterygota for those in which the wing development is entirely external. Of existing insects 90 per cent. belong to the Endopterygota. At the same time we have no evidence that any Endopterygota existed amongst Palæozoic insects, so that the phenomena of endopterygotism are comparatively recent, and we are led to infer that the Endopterygota owe their origin to the older Exopterygota. In Endopterygota the wings commence their development as invaginations of the hypodermis, while in Exopterygota the wings begin—and always remain—as external folds or evaginations. The two modes of growth are directly opposed, and at first sight it appears that this fact negatives the view that Endopterygota have been derived from Exopterygota.

Only three hypotheses as to the origin of Endopterygota can be suggested as possible, viz.:—(1) That some of the Palæozoic insects, though we infer them to have been exopterygotous, were really endopterygotous, and were the actual ancestors of the existing Endopterygota; (2) that Endopterygota are not descended from Exopterygota, but were derived directly from ancestors that were never winged; (3) that the predominant division—*i.e.*, Endopterygota—of insects of the present epoch are descended from the predominant—if not the sole—group that existed in the Palæozoic epoch, viz., the Exopterygota. The first hypothesis is not negatived by direct evidence, for we do not actually know the ontogeny of any of the Palæozoic insects; it is, however, rendered highly improbable by the modern views as to the nature and origin of wings in insects, and by the fact that the Endopterygota include none of the lower existing forms of insects. The second hypothesis—to the effect that Endopterygota are the descendants of apterous insects that had never possessed wings (*i.e.*, the Apterygogenea of Brauer and others, though we prefer the shorter term Apterygota)—is rendered improbable from the fact that existing Apterygota are related to Exopterygota, not to Endopterygota, and by the knowledge that has been gained as to the morphology and development of wings, which suggest that—if we may so phrase it—were an apterygotous insect gradually to develop wings, it would be on the exopterygotous system. From all points of view it appears therefore probable that Endopterygota are descended from Exopterygota, and we are brought to the question as to the way in which this has occurred.

It is almost impossible to believe that any species of insect that has for a long period developed the wings outside the body could change this mode of growth directly for an internal mode of development of the organs in question, for, as we have already explained, the two modes of growth are directly opposed. The explanation has to be sought in another direction. Now there are many forms of Exopterygota in which the creatures are almost or quite destitute of wings. This phenomenon occurs among species found at high elevations, among others found in arid or desert regions, and in some cases in the female sex only, the male being winged and the female wingless. This last state is very frequent in Blattidæ, which were amongst the most abundant of Palæozoic insects. The wingless forms in question are always allied to winged forms, and there is every reason to believe that they have been really derived from winged forms. There are also insects (fleas, &c.) in which

metamorphosis of a holometabolous character exists, though the insects never develop wings. These cases render it highly probable that insects may in some circumstances become wingless, though their ancestors were winged. Such insects have been styled anapterygotous. In these facts we have a clue to the change from exopterygotism to endopterygotism, namely, by an intermediate period of anapterygotism.

Although we cannot yet define the conditions under which exopterygotous wings are suppressed or unusually developed, yet we know that such fluctuations occur. There are, in fact, existing forms of Exopterygota that are usually wingless, and that nevertheless appear in certain seasons or localities with wings. We are therefore entitled to assume that the suppressed wings of Exopterygota tend to reappear; and speaking of the past, we may say that if after a period of suppression the wings began to reappear as hypodermal buds while a more rigid pressure was exerted by the cuticle, the growth of the buds would necessarily be inwards, and we should have incipient endopterygotism. The change that is required to transform Exopterygota into Endopterygota is merely that a cell of hypodermis should proliferate inwards instead of outwards, or that a minute hypodermal evaginated bud should be forced to the interior of the body by the pressure of a contracted cuticle.

If it should be objected that the wings so developed would be rudimentary, and that there would be nothing to encourage their development into perfect functional organs, we may remind the reader that we have already pointed out that imperfect wings of Exopterygota do, even at the present time under certain conditions, become perfect organs; and we may also add that there are, even among existing Endopterygota, species in which the wings are usually vestiges and yet sometimes become perfectly developed. In fact, almost every condition that is required for the change from exopterygotism to endopterygotism exists among the insects that surround us.

11. *Classification.*—The application of morphological (including developmental) studies to the classification of insects necessarily renders the perfection of a natural system a slow process. So far as it has been carried out, it has not resulted in a tendency to reduce the number of Orders, but rather to increase them. Twenty-two primarily different kinds of insects must at present be recognized, viz.: (1) Collembola, (2) Thysanura, (3) Mallophaga, (4) Anoplura (or Pediculidæ), (5) Aphaniptera (now frequently called Siphonaptera), (6) Orthoptera, (7) Perlidæ (or Plecoptera), (8) Psocidæ, (9) Termitidæ (or Platyptera), (10) Embiidæ, (11) Ephemeridæ, (12) Odonata, (13) Thysanoptera, (14) Hemiptera (or Rhynchota), (15) Neuroptera, (16) Panorpatæ (or Mecaptera), (17) Trichoptera, (18) Lepidoptera, (19) Coleoptera, (20) Strepsiptera, (21) Diptera, (22) Hymenoptera. These groups are of most unequal extent, some of them numbering a score or two of species, and some of them scores of thousands. Although various attempts have been made to combine these twenty-two groups into a smaller number of divisions, they have none of them received general assent. We may, however, mention that groups 1–5 are purely apterous insects; that the members of groups 6–14 have the wings placed outside the body on the back during development, and form the Exopterygota; while groups 15–22 form the Endopterygota, the wings during development being quite invisible externally. Great difficulty is experienced in classifying the purely apterous divisions. 1 and 2, Collembola and Thysanura, are usually separated from the others under the name Apterygogenea, or that of Apterygota or Aptera; and it is supposed by many that not only are they themselves wingless, but that their ancestors were always in the same state of winglessness. Groups 3–5 are, on the contrary, supposed to be descended from winged forms, and have been termed Anapterygota. The Anapterygota consist entirely of epizoic forms (*i.e.*, creatures dwelling on the bodies of other living animals), and are of two very distinct kinds. In Mallophaga and Anoplura the parasitic, or epizoic, life is complete and there is no metamorphosis, while in the fleas (Aphaniptera) metamorphosis is strongly developed and the epizoic life is but partial.

12. *Ethology.*—Recent observation of the habits and instincts of insects has resulted in accentuating the great difference that exists between the intelligence of the insect and that of the vertebrate. The subject is much obscured by the difficulty that exists in agreeing as to the terms that are used in discussing it. In making use of the words reason and intelligence in connexion with insects we are met by the difficulty that we know but little of the nervous actions, and nothing of the consciousness that may or may not accompany them in insects, while in ourselves we form our conclusions as to reason and intelligence largely by the nature of the consciousness that accompanies the nervous processes. Some naturalists deny any intelligence to insects, and contend that their actions are merely reflex. It is, however, impossible to compare the insect mind with any one set of the categories in which we class our own actions. In short, the proceedings of insects must be judged by the results the species attains, and not by a comparison with the methods we ourselves should use for attaining similar results. If we view the subject in this light, we find a thorough harmony to exist between the main peculiarities of the insect's life and what we must perforce style its mental characteristics. There are, however, great distinctions in the lives of the different kinds of insects, so that it is impossible for us here to pursue this subject in detail.

The most surprising of all the discoveries in entomology are those that have been made as to *social insects.* The number of kinds of these is comparatively small. They are all included amongst the termites, wasps, bees, and ants. All these social insects exhibit a more or less considerable departure from the biological characters of the non-social insects. The generations are not isolated, but overlap; the life of the individual is unusually long, and, what is more to the point, it is the adult or perfected stage of the life that is prolonged. The young are fed from the mouths of the nurses, and the food is modified by the processes of the feeder's body. Most remarkable is the fact, that though the communities of social insects often include a countless number of individuals, the work of reproduction is limited to an extremely small number of them, and in the highest developments of insect socialism to a single mother. This individual is thus, in some cases, the immediate progenitor of scores of thousands of individuals, all living with her and assisting in her work, inasmuch as they feed and care for her young. This social system is therefore a highly perfected form of family life.

Perhaps the most remarkable fact as regards the higher societies of insects is that though the individuals composing a community are the offspring of one mother, and (in the case of the social Hymenoptera) of a single copula, yet they do not resemble their parents, and, moreover, exhibit a good deal of difference among themselves, consisting of soldiers of different grades, as well as of workers and nurses, each kind being formed so as to adapt it to its special duties. The way in which these castes are produced has been much debated. There is much variety in social insects; in the Hymenoptera all the castes are composed of the altered females (sometimes called

neuters). One set of *savants* contends that the whole of these castes are directly due to food. It is not supposed that there is a particular kind of food for producing each caste, but rather that the nutritive powers of the foods supplied are different, and affect the growth of the larvæ, and possibly the growth of the eggs in the ovaries; variations in the moment of the development at which a change of food is made, and the fact that the food may affect the development of some organs more than others may be important, and, combined with the correlation of organs, may be adequate to produce the results. This has been supported by Grassi and Herbert Spencer. A very different view has been maintained by Weismann. He considers that the various castes may be accounted for by supposing each egg to contain a variety of rudiments (to an uncertain extent) for each organ, and that the food merely excites the development of one set of rudiments rather than another. Individuals intermediate between the various castes, and others of anomalous developments, are occasionally found; and as it is not possible to believe in special rudiments as their cause, it is clear that we must admit some amount of plasticity in the development of the rudiments. Hence the existence of a variety of rudiments need not be invoked, and can only be admitted when the rudiments are actually demonstrated.

AUTHORITIES.—The works and papers published on insects at present number annually more than 1000. It is impossible to give here a list of even the more important of those published since 1880. In the following list we mention one or two of the more recent in several departments; these will be found in most cases to include references to earlier works. **General Works**:—A. S. PACKARD. *Text-Book of Entomology*. London, 1898.—D. SHARP. "Insects," the *Cambridge Natural History*, vol. v., 1895; vol. vi., 1899. London. —C. JANET. Insomnia.—Inability to sleep is a common and troublesome feature of most illnesses, both acute and chronic. It may be due to pain, fever, or cerebral excitement, as in *delirium tremens*, in which the patient sometimes does not obtain a moment's sleep for several days and nights together, or it may be due to organic changes in the brain. The treatment, when failure to sleep occurs in connexion with a definite illness, is part of the treatment of that illness. But there is a form of sleeplessness not occurring during illness to which the term "insomnia" is commonly and conveniently applied. It must not be confounded with mere occasional wakefulness caused by some disturbance or irritation or minor discomfort, such as indigestion, nor with the "bad nights" of the valetudinarian, who complains of not having "closed an eye" all night, after several hours of sound sleep during the day. Real insomnia consists in the prolonged inability to obtain sleep sufficient in quantity and quality for the maintenance of health. It is a condition of modern urban life, and may be regarded as a malady in itself. It is a very troublesome and serious condition, and probably the most potent factor in causing those nervous breakdowns which are ascribed to "overwork." It may occur as a sequel to some exhausting illness, notably influenza, which affects the nervous system long after convalescence. But it very often occurs without any such cause. The patients are usually men of mature age, though youth may suffer from insomnia also, brought on by work for examinations, for instance, or some other over-stimulation of the brain. But in youth the cause is easily removed as a rule, and the tissues quickly regain their normal tone. Continued deprivation of sleep, however, produces the most serious effects even in the young. Later in life the cause is less easily removed and the recuperative powers are less vigorous. Professional and business men are the most frequent sufferers, because the strain of mental work and anxiety falls more heavily upon them than upon any other class. Insomnia is comparatively rare among the poor, who do little or no brain work, and, living always from hand to mouth, with nothing to lose, never feel the same anxiety. It may be brought on by some exceptional strain, by long-continued worry, or by sheer overwork. The broad pathology is simple enough. It has been demonstrated by exact observations that in sleep the blood leaves the brain automatically. The function is rhythmical, like all the vital functions, and the mechanism by which it is carried out is no doubt the vaso-motor system, which controls the contraction and dilation of the blood-vessels. In sleep the vessels in the brain automatically contract. When the brain is working actively, on the contrary, a plentiful supply of blood is required, and the vessels are dilated. If the activity is carried to great excess the vessels become engorged, the mechanism does not act, and sleep is banished. Hence the common phenomenon of children being unable to sleep "for excitement." In insomnia this condition has become fixed. It seldom produces absolute sleeplessness. What happens is that a man goes to bed and cannot get to sleep for hours. He is turning things over in his head. Eventually he falls asleep towards morning, and after a brief period of unconsciousness he is awakened to the day's work again. Or it may be that he falls asleep on going to bed and wakes up not long afterwards, to lie broad awake for the rest of the night. In either case he has not had sufficient cerebral rest, and returns heavy and dull to his work, which once more goads the tired brain into excitement and renews the evil. *Crescit indulgens sibi dirus hydrops.* The longer it goes on the more fixed becomes the condition of cerebral engorgement, until the brain gives way and a touch of paralysis, loss of memory, mental aberration, or complete collapse follows.

When such a breakdown has happened or is pending the only treatment is complete rest, combined, if possible, with change of air and scene; but if the mischief has gone far it will take very long to repair, and may never be repaired at all. In no matter of health is the importance of "taking it early" more pronounced. Delay is the worst economy. A few days' holiday at the commencement of trouble may save months or years of enforced idleness. Sea-air sometimes acts like a charm. But if it is impossible, as it sometimes is, to give up work and leave worry behind, even for a short time, sleep should be carefully wooed by every possible means. In the first place, plenty of time should be devoted to it, and no chance should be missed. That is to say, the night

should not be curtailed at either end, and if sleepiness approaches in the daytime, as it often does, it should be encouraged. It is better to lie still at night and try to sleep than to give way to restlessness, and a few minutes snatched in the daytime, when somnolence offers the opportunity, has a restorative effect out of all proportion to the time occupied. Then all accidental causes of disturbance should be avoided. Lights and sounds should be excluded, comfort studied, and digestion attended to. Very often the trouble might be cut short if the patient and the other people in the house realized the seriousness of the condition and took pains to ameliorate it in little things. If a hypochondriacal tendency is present conversation should be sympathetic, but cheerful and encouraging. Fresh air is a great help. As much time should be spent out of doors as possible, and exercise, even to the point of fatigue, may be found helpful. But this requires watching: in some cases bodily exhaustion aggravates the malady, and in particular bicycle exercise, which has a peculiarly exhausting effect on some people, should be used with care. In abstemious persons a little alcohol often acts as a complete restorative. The following case is instructive. Mr X., a professional man, carrying a great responsibility upon his shoulders, was subjected to a specially severe strain of anxiety, work, and worry. Though a strong man, he was always "a bad sleeper," and under the strain insomnia came on; his health completely gave way, a slight attack of paralysis supervened, and he had to spend months in the south of Europe. Two years later the same strain recurred, but more severe and more prolonged; yet he slept quite well, and went through it with ease. The sole difference was that he had been induced to take a glass of wine every day. Its effect was immediate; he slept better and felt better than he had done for years. A little hot food with some stimulant immediately before going to bed is useful in inducing sleep, and persons who are apt to wake in the night and lie awake for hours may obtain relief by the same means. A little light reading, or the recalling of pleasant experiences, is sometimes a useful way of disengaging the mind from oppressive thought on going to bed. Hypnotic drugs, which have greatly multiplied of late years, should only be taken under medical advice. They have their use, but the principle of obtaining sleep by such means is not a sound one. The real end to aim at is the restoration of the natural function, and the substitution of artificial sleep, which differs in character and effect, tends rather to prevent than to promote that end.

Like many other morbid conditions, insomnia is more easily prevented than cured. It is really the penalty exacted by Nature for a long course of systematic defiance. When a man's sleeping apparatus is in good working order it may be thrown out of gear for a short time by some great strain, but it will recover in the course of a few days at most, and will not inflict upon him the horrors of insomnia. But when it has been ruined by prolonged interference it stops work altogether under the strain. Habits of life interfere with it by curtailing the time required for the due fulfilment of the rhythmical cycle of this vital function. It may be said with confidence that in modern town life men habitually sleep too little, and this is even more injurious to them than the other habit of eating too much. They "burn the candle at both ends." They get up in the morning and go to their work, but in the evening instead of going to bed they go out to dinners and parties and theatres and other distractions. Time which should be given to sleep is devoted to something else. A little of it does no great harm, but regular and prolonged interference with the mechanism gradually destroys it. The adaptability of the human organism is great, and no effects may be observed for years; but Nature is not mocked, and when a special strain comes she manifests her resentment in insomnia. If no such occasion arises, the penalty is still exacted in the form of premature death. Thus the time robbed is paid back again. The premature death of hard-working professional and business men, which is so common a feature of modern life, is probably due more to insufficiency of sleep than to any other cause, though they may never develop actual insomnia. The lesson is the same, namely, the importance of taking sufficient sleep as a regular habit. What constitutes sufficient sleep depends upon the individual. Persons differ so much that it is no more possible to lay down a fixed amount for every one than it is to prescribe a fixed quantity of food. Besides, the requirements of the same persons vary under different conditions; one needs more sleep in cold weather than in hot, in winter than in summer, when tired than when not. The only rule to go by is to have one's sleep out, so as to feel thoroughly refreshed on awaking, as children do. Less than that is insufficient.

Insterburg, a town of Prussia, province of East Prussia, 57 miles by rail east of Königsberg. It has manufactures of machinery and bricks, iron foundries, flax-spinning mills, bone mills, sawmills, distilleries and breweries, and an active trade in agricultural produce. It is an important railway junction. Population (1885), 20,914; (1900), 27,787.

Instinct.—There is little to add in general to the treatment of this subject by Romanes in the earlier volumes of this Encyclopædia (ninth edition), but a good deal of interesting work has been done in the way of detailed inquiry into the problems raised by the application of the doctrine of heredity (*q.v.*) to its explanation, mainly by Lloyd Morgan and Lord Avebury in biology, and by Wundt, W. James, and Stout in psychology. While it is generally conceded that instinct in animals covers "congenital characters," and intelligence "acquired characters," it is frequently difficult to decide how far intelligence modifies instinct or instinct stimulates intelligence. The actual part, too, played by natural selection is disputed, the genesis of instinct being attributed by Wallace to natural selection alone, by Spencer to inherited habit, by Romanes to both. Lloyd Morgan, the chief authority at the present time, regards the direct transmission of acquired modes of behaviour as non-proven. Heredity, the latter points out (*Proc. Roy. Inst.*, 1899), plays a double part:—

> It provides, through natural selection or otherwise, an outline sketch of relatively definite behaviour, racial in value; it provides also that necessarily indefinite plasticity which enables an animal to acquire and to utilize experience, and thus to reach adaptation to the circumstances of its individual life. It becomes, therefore, a matter of practical inquiry to determine the proportion which the one kind of hereditary legacy bears to the other. Observation seems to show that those organisms in which the environing conditions bear the most uniform relations to a mode of life that is relatively constant are the ones in which instinct preponderates over intelligent accommodation; while those in which we see the most varied interaction with complex circumstances show more adaptation of the intelligent type. The growth of individual plasticity of behaviour in race development would seem to be accompanied by a disintegration of the definiteness of instinctive response, natural selection favouring rather the plastic animal capable of indefinitely varied accommodation than the more rigid type, whose adaptations are congenitally defined.

INSURANCE.

I. General History.

During the years since the article "Insurance" in the ninth edition of this work was written, the practice of insurance has extended with unprecedented rapidity, partly in novel forms. While its several branches, such as life insurance, casualty insurance, and others, have each had an independent and characteristic development, it should be observed that all these together form an institution peculiar to the modern world, the origin and growth of which attest a remarkable change in men's ideas and habits of thought—a change the character and extent of which, if fully traced, would fill an impressive chapter in the history of civilization. Some sketch of it will fittingly introduce a brief account of the recent growth and present condition of each branch of the business, especially in Great Britain and America.

The simplest and most general conception of insurance is a provision made by a group of persons, each singly in danger of some loss, the incidence of which cannot be foreseen, that when such loss shall occur to any of them it shall be distributed over the whole group. Its essential elements therefore are foresight and co-operation; the former the special distinction of civilized man, the latter the means of social progress. But foresight is possible only in the degree in which the consequences of conduct are assured, *i.e.*, it depends on an ascertained regularity in the forces of nature and the order of society. To the savage, life is a lottery. In hunting, rapine, and war, all his interests are put at hazard. The hopes and fears of the gambler dominate his impulses. As nature is studied and subdued, and as society is developed, the element of chance is slowly eliminated from life. The measure of civilization is the degree in which men rely on the future, in which foresight guides conduct, and life, ceasing to be a series of hazards, becomes a series of actions planned with the reasonable expectation of definite results. The gambling spirit survives, indeed, often assuming new and refined forms in the most advanced communities, but it is always the foe of civilization. In a progressive society, education, science, invention, the arts of production, with regular government and civil order, steadily work together to narrow the realm of chance and extend that of foresight. But after they have done their best to conquer the forces of nature and regulate human passions, so that achievement shall follow purpose with uniformity, there remain certain events which may disturb all anticipations, and in spite of any man's best wisdom and effort may deprive him of the fruits of his labour. These are mainly of two classes: (1) damage to property by the great forces of nature, such as lightning and hail, by the perils of the sea, and by fire; (2) premature death. A useful life has an economical value. But no skill can make certain its continuance to its normal close, and in each individual case its duration is indeterminate. In the reasonable expectation that it will last until a competence is gained or the family ceases to be dependent, young men marry; but some will die too soon, and in the aggregate multitudes are left destitute. Both classes of loss are alike, in that they fall on individuals in the mass who are not known beforehand nor selected by any traceable law. But the sufferers are ruined, while the same pecuniary loss, if distributed over the whole number, would be little felt. Wherever the sense of community has existed this has been discerned, and some effort made to act upon it. Thus in feudal Europe it was customary for the houses of vassals to be restored after fire at the cost of the estate. In England in the 17th century the Government practised a method of relief after accidental fires. When such a loss was proved to the king in council, the chancellor sent a king's brief to churches, sheriffs, and justices, asking contributions, and trustees for the sufferers administered the funds collected. But under the last two Stuarts gross frauds resulted, and the system fell into disrepute and disuse. At best, the voluntary relief provided by charity after losses are incurred is but sporadic and irregular. Insurance begins when the liability to loss is recognized as common, and provision is made beforehand to meet it from a common fund. The efficient organization of communities or groups for this purpose is an essentially modern achievement of social science, and has become one of the chief commercial and moral factors of civilization. But the history of the conception in its formative stages is extremely obscure.

Its first appearance in business life is often sought in the marine loans of the ancient Greeks, fully described by Demosthenes. Money was advanced on a ship or cargo, to be repaid with large interest if the voyage prosper, but not repaid at all if the ship be lost, the rate of interest being made high enough to pay not only for the use of the capital, but for the risk of losing it. Loans of this character have ever since been common in maritime lands, under the name of bottomry and respondentia bonds. (See below, *Marine Insurance*.) But the direct insurance of sea-risks for a premium paid independently of loans began, as far as is known, in Belgium about A.D. 1300. During the next century the risks of insurance for the usual voyages between London and Continental ports were carefully considered, and customary rates became established. Ordinances and legislation for the regulation of marine insurance grew up, and show that the practice was recognized as a legitimate business. In his address in opening Elizabeth's first Parliament in 1559, Sir Nicholas Bacon said, "Doth not the wise merchant in every adventure of danger give part to have the rest assured?" In 1601 Parliament created a commission to decide disputes under contracts for marine insurance, and the preamble of the Act (43 Eliz. ch. 12) expresses the best thought of the British mind in that day upon the subject. Thus the business of marine insurance was intelligently and wisely practised three centuries ago. The ratio of losses to voyages, the varying hazards of particular seas and seasons, and the seaworthiness of different classes of vessels, must have been roughly studied to yield a recognized basis for rates. But the underwriters were private persons, acting independently, so that the insured lacked the benefit of large aggregations of capital to make his contract safe; while the insurer, who took one or a few risks, was without the security of large averages, and might be crushed by an exceptional loss. A partial remedy was gradually reached in London. Men who had capital to employ in this hazardous business used to meet at fixed hours when shipowners and merchants could negotiate with them. The higgling of the open market, in view of all the circumstances of each risk—as the character and condition of the ship, its crew and cargo, the length and route of the voyage, the season, the current rate of interest and profits—determined the rate of premium; and when this obtained general assent, the written agreement was signed by each underwriter for that part of the risk which he assumed. Towards the end of the 17th century these meetings were held in Lloyd's Coffee-house,

and their simple practice gradually grew into the complete and complicated system of marine insurance now general. The underwriters together evolved rules and improved methods, but continued for generations to insure severally, without corporate powers or common responsibility, so that the name Lloyd's became throughout the commercial world the symbol of marine insurance. More recently the name has been adopted in the United States by associations of private or individual underwriters as distinguished from insurance corporations.

Although the underwriters at Lloyd's often considered and assumed other than marine risks, and made contracts some of which were merely wagers on public or private events, there is no record of insurances by them against fire on land. But fire insurance, it is vaguely known, had previously been practised, in a crude form, in several European cities. In 1635, and again in 1638, citizens of London petitioned Charles I. for a patent of monopoly to insure houses at the rate of one shilling yearly for each £20 of rent, the association to repair or rebuild those burned, to maintain a perpetual fire-watch in the streets, and to pay £200 yearly towards rebuilding St Paul's Cathedral until finished. The attorney-general approved the project, but in the disorders of the kingdom it was forgotten. The Great Fire of 1666 revived interest in the subject, and the discussion of it soon led to definite views and practical measures. In May 1680 a private Fire Office was opened "at the back side of the Royal Exchange" to insure houses in London, by assuming the risk of loss to a fixed amount for a fixed premium, namely, 2½ per cent. of the yearly rent for brick houses and 5 per cent. for frame houses, the rent being always assumed to be one-tenth of the value of the fee. The estimates of the promoters are interesting. In the fourteen years since the Great Fire 750 houses had been burned in London, with an average loss of £200. A fund of £40,000 subscribed as guaranty was to be increased by £20,000 for every 10,000 houses insured, and the interest of the fund alone, therefore, might be expected to meet all losses and leave a surplus. Thus the security was perfect and the promise of profit great. Meagre as was the basis of facts for the calculations, and crude as was the statistical method employed, the insurance offered met a general want, and the business grew rapidly. Within a year a strong demand was heard that the City of London should itself insure the houses of its citizens, and the Common Council voted to do so at lower rates than the Fire Office. But the courts put a speedy end to this movement, holding that the charter conferred on the City no power to transact such business. Thus the socialistic theory that insurance is properly a branch of government is almost as old as the business itself, though it has never found favour or been practically tested on a large scale in Great Britain or America.

The next notable step in the evolution of modern methods was the organization of mutual insurance associations. In 1684 the Friendly Society was organized. Each member paid a small entrance fee for expenses, made a cash deposit as a reserve for emergencies, to be returned at the end of his term, and agreed to meet equitable assessments for current losses. Payments were computed on the assumption that one house in 200 is burned every fifteen years. The rivalry between the proprietary and the mutual systems began at once, and has continued till now. In 1686 "the Fire Office at the back side of the Royal Exchange" petitioned for a patent of the fire insurance policy, and a monopoly of its issue for thirty-one years. The Friendly Society opposed the grant. The most eminent lawyers for both were heard by the king in council, and on 30th January 1687 King James II. decided the case. No charter was granted, but the Fire Office might continue its business, having a monopoly for one year. Thereafter the Friendly Society might for three months sell policies, but must then suspend for three months, and so on for alternate quarters. But the Fire Office must pay the ordinance service for its work in extinguishing fires, the amount to be fixed for each fire by the king. This was the first appearance of the plan, so widely prevalent in after years, of imposing on insurance companies the support of fire departments; that is, of taxing the prudent who insure to protect the reckless who do not.

After 1688 the atmosphere of England was freer, and underwriting was soon practised without special license. In 1704 the societies began to insure household goods and stocks in trade, and the insurance of personal property rapidly became as important as that of buildings. In 1706 the Sun Fire Office was founded, and began to issue policies on both real and personal property in all parts of England. Other associations arose in quick succession, of which the Union Fire Office, dating from 1714, and the Westminster from 1717, still survive. Before 1720 both fire and marine insurance had become general in all great centres of trade. But life insurance was as yet hardly conceived. Sporadic evidences that it was needed, and that men were feeling after it, occur in very early records. It was a mediæval custom to advance to a mariner goods or money, to be restored with large additions, but only in case of safe return; or to contract, for a sum in hand, to ransom him if captured by pirates, or to pay a fixed amount to his family if he were lost. To evade the usury laws life annuities were often sold at a low rate, redeemable for a stipulated sum. Life estates were sold upon some guess at their probable duration; and leases, especially of Church lands, were made for one, two, or three lives on rude and conventional estimates of the time they would run. Thus there was a commercial and social pressure for some intelligent method of valuing life contingencies. But the direct insurance of life, as a means of reducing the element of chance in human affairs, was hardly thought of. Indeed, such contracts were commonly regarded as mere forms of gambling, and were prohibited in France as against good morals.

The earliest known policy of life insurance was made in the Royal Exchange, London, 18th June 1583, for £383, 6s. 8d. for twelve months, on the life of William Gibbons. Sixteen underwriters signed it, each severally for his own share, and the premium was 8 per cent. The age of the insured is not referred to, nor was it then considered, except when far advanced, in fixing the premium. Gibbons died 29th May 1584. The underwriters refused to pay, alleging that twelve months, in law, are twelve times twenty-eight days, and that Gibbons had survived the term. The court, of course, enforced payment. A few instances of similar contracts are found, mostly in judicial records, during the 17th century; but every such transaction was justly regarded as a mere wager, at least on the part of the insurer. It could not be otherwise until the principles of probability and the uniformity of large averages were understood and trusted; that is, until a new science should be created, and its authority established in the business community. A few great thinkers were pondering the subject, groping for principles which were profoundly to modify the practical reasoning of after-generations. But their work first obtained wide recognition upon the publication of the *Ars Conjectandi*, the posthumous treatise of James Bernouilli, in 1713. Meanwhile the social need for insurance continued to express itself in empirical efforts, which at least helped to make clearer the problems to be solved. Thus in 1699 "The Society of Assurance for Widows and Orphans" was

founded in London, a crude form of what is now called an assessment company. Each of 2000 healthy men under fifty-five years of age was to pay 5s. as entrance fee, 1s. quarterly for expenses, and 5s. at the death of another member; and at his own death his estate should receive £500, less 3 per cent. On default in any payment his interest was forfeited. The society lasted about eleven years, and the accounts of its eighth year are preserved, showing the payment of £5200 upon twenty-four claims. The economic significance of this society lies in its distinct recognition of the principle of association for the distribution of losses. Together with the Friendly Society, it shows that this principle had now been so widely grasped by business men that, when embodied in a practical venture, it found substantial support.

The conception of a corporation as an artificial person to hold property and support obligations uninterrupted by the death of individuals, was found in Roman law and custom. Its first use in modern business enterprise was perhaps the Bank of St George in Genoa, about A.D. 1200, a joint-stock company with transferable shares, whose owners were liable only to the amount of their shares. In England the Crown, itself the chief and type of corporations sole, was the source of chartered rights, and from about 1600 the principle steadily gained recognition, the advantages of incorporation being attested by the successes of the great trading companies. Experience showed that the corporate form was the obvious remedy for the chief difficulties in the practice of insurance. Single risks were but speculative wagers; a great number must be taken together to obtain a trustworthy average. A larger capital than an average private fortune was demanded as a guaranty, and this capital must not be exposed to the dangers of trade, but set aside for the special purpose. Individual underwriters may die or fail; only a permanent institution can be trusted in long contracts. Several projects were devised on this basis. Early in the 18th century, indeed, the English Government refused a charter for marine insurance, declaring that corporate insurance was an untried and needless experiment, while private underwriting was satisfactory and sufficient. But in 1720, when two sets of promoters offered £300,000 each for a charter, exclusive of other associations, though not of individuals, to insure marine risks, Parliament chartered the Royal Exchange and the London Assurance Company with a monopoly to this extent. The business disappointed its projectors at first, and the Government accepted half the price rather than revoke the grant. In 1721 the companies extended their operations to fire insurance throughout England.

Thus the principle of insurance had now become a distinct part of the common stock of thought in enlightened nations, and gradually, by association with successive new ideas, plans, and methods, was developed into a business or trade, which before the middle of the 18th century already formed an essential element of the social scheme. Most of the modern forms of insurance against the elements were known, and at least crudely practised. Risks were defined, appraised, and roughly classified; premiums were determined with some regard to experience, and attempts were made to collect, classify, and study the facts. Corporate and private enterprise competed for patronage, mutual and proprietary methods were discussed and tried; disputed contracts were interpreted and enforced by the courts, laying the foundations of insurance law. But there was no scientific basis for the business. Premiums were fixed, not by computation from known facts or reasonable assumptions, but by guess and the higgling of the market. Only the competition of capital checked the extortionate demands of underwriters. The first important steps towards a scientific valuation of hazards were taken in dealing with the class of risks hitherto so much neglected, those which depend upon human mortality. Marine and fire insurance had their origin in the pressure of need. The practice began before a theory existed. Men who must have protection were ready to pay so largely for it that capital was tempted to feel its way by the roughest estimates. But life insurance had its origin in the scientific study of the facts of human mortality, which suggested the possibility of provision against premature death. Both marine and fire insurance became general before there was any intelligent study of the risks by statistical or mathematical methods, nor can it be said that much progress has since been made towards establishing a scientific basis for the valuation of risks in these classes. But life insurance may be said to have been impossible until the theory of probabilities had become a recognized part of the common stock of ideas.

The value of insurance as an institution cannot be measured by figures. No direct balance-sheet of profit and loss can exhibit its utility. The insurance contract produces no wealth. It represents only expenditure. If a thousand men insure themselves against any contingency, then, whether or not the dreaded event occurs to any, they will in the aggregate be poorer, as the direct result, by the exact cost of the machinery for effecting it. The distribution of property is changed, its sum is not increased. But the results in the social economy, the substitution of reasonable foresight and confidence for apprehension and the sense of hazard, the large elimination of chance from business and conduct, have a supreme value. The direct contribution of insurance to civilization is made, not in visible wealth, but in the intangible and immeasurable forces of character on which civilization itself is founded. It is pre-eminently a modern institution. Two centuries ago it had begun to influence centres of trade, but the mass of civilized men had no conception of its meaning. Its general application and popular acceptance began within the last three generations, and its commercial and social importance have multiplied a hundredfold within living memory. Its development measures and promotes the growth of the spirit of community. It has done more than all gifts of impulsive charity to foster a sense of human brotherhood and of common interests. It has done more than all repressive legislation to destroy the gambling spirit. It is impossible to conceive of our civilization in its full vigour and progressive power without this principle which, in all its varied applications together, unites the fundamental law of practical economy, that he best serves humanity who best serves himself, with the golden rule of religion, "Bear ye one another's burdens."

II. Casualty and Miscellaneous Insurance.

Before proceeding with an account of the standard institutions of fire and life insurance, it is proper to glance at the recent vast extension of casualty insurance, which has assumed new and varied forms, and to notice certain novel applications of the insurance principle to other special classes of events. The novelty of these enterprises, however, is not in the general idea underlying each of them. In almost every instance in which insurance has been extended, so as successfully to cover new kinds of risks, it will be found that the suggestion is nearly as old as the practice of life insurance. Many more kinds of insurance than are even now found useful were attempted more than a century ago. But no statistical basis then existed for determining the probability of loss from various casualties, nor had modern methods of canvassing, accounting,

proving and checking losses, reached the perfection now recognized as necessary for efficiency and safety. The various branches of business which, in distinction from the great standard institutions of life, fire, and marine insurance, are commonly treated in the mass as miscellaneous insurance, differ widely in their subjects and methods. The most general of them, and that most widely known, is insurance against personal injury by accidents of every kind. Much has already been done by the companies in collecting and analysing facts, especially from their own experience, so as to determine the average risk of injury and disablement among different classes of men; and thus progress is steadily made towards a trustworthy basis of rates. But there is as yet no such union of effort among them to combine their resources for such purposes as among the life companies, nor does the subject admit of treatment so exact as that of human mortality. Hence it is impossible to speak of a theory of accident insurance in a scientific sense; and in its practice premiums and necessary reserves are determined by the trained business judgment of individual managers, guided by successive experiments, rather than by the calculations of actuaries from statistical collections of facts.

The insurance of railway travellers against injury upon trains was the first form of accident insurance which proved widely acceptable. This is still practised as a special business by several companies, tickets, entitling the purchaser or his family to a fixed compensation in case of his injury or death, being offered for sale with the railway tickets. Another special form of insurance is that against injury while riding a bicycle, often including also the rider's risk of liability for injuring any other person. But the development of insurance against personal injuries, which is most characteristic of the times, is the wholesale insurance of the employer against liability to the employed for accidental injuries sustained in his service. This was first undertaken on a large scale by the "Employers' Liability Assurance Corporation of London," founded for the purpose in 1880, immediately after the passage of the Employers' Liability Act by Parliament, which made employers of labour liable for injuries sustained in their service to an extent unknown to the common law. This company has gradually adapted its methods to the needs of its clients, and in 1886 extended its agencies beyond the United Kingdom, especially in America. The business has been vigorously prosecuted, and is now carried on by at least ten companies in Great Britain and seven in the United States, while nine new associations were registered in England for this special purpose in 1899. The policies are issued to the owners or operators of mills, mines, factories, railroads, and vessels, to builders and contractors, or other large employers of labour, agreeing to indemnify them for any loss to which they may be subjected, at common law or by statute, in consequence of bodily injuries suffered by any employee while engaged in their service. The insurance company undertakes the investigation and settlement of each claim within the limits prescribed by the policy, and conducts any litigation which may result. The adjustment of damages is made with more economy and skill by the companies than is usually possible for the employer, and the danger of fraudulent claims is largely reduced by methods experience has taught them. The price charged for such insurance is commonly a small percentage of the aggregate wages paid during the term, fixed in view of the peculiar hazards of the employment. But special forms of collective insurance of a similar kind are issued to cover liability for injuries suffered by casual visitors in theatres, in passenger elevators, or in the neighbourhood of factories or the works of contractors, often for fixed premiums.

The most common form of accident insurance, however, is still represented by the policy which promises the assured a fixed sum in case of death by accident, and a weekly compensation during disability from such a cause. Many policies also specify a sum to be paid for the loss or permanent damage of a member, as an eye, a hand, or foot. A recent extension of the personal accident policy is the addition of some form of health insurance, especially the grant of a weekly sum to the insured during incapacity for work caused by certain named diseases. Fourteen companies practising accident insurance against personal injuries in the United States reported for 1899 upon this class of policies aggregate premium receipts of $5,237,363, and losses paid $2,325,399. Besides the business of these stock companies, with fixed premiums, there are more than sixty associations in the United States organized for insurance against personal injury by accident, and relying upon the assessment of members to pay claims as they mature. Most of these are local and ephemeral; but a number of them, formed by men engaged in common pursuits, for mutual protection, have attained importance. Such are especially some of the commercial travellers' and the railway employees' accident associations, and a few connected with the Masonic or similar beneficiary orders. Eighteen of these societies reported the payment to members in 1899 of $874,084 in claims.

Another large class of casualty insurances applies to various forms of damage to property. The branch which seems most to have attracted promoters is the insurance of plate glass against fracture, which is carried on by at least twenty-two companies in Great Britain, and is the only business of many of them. Although twelve of these companies collected in 1898 less than £200 each in premiums, yet six new associations for this exclusive purpose were registered in England in 1899. In the United States there are five corporations which insure plate glass alone, with an aggregate capital of $650,000, annual premium receipts (1899) of $978,129, and risks in force of about $46,000,000. Seven other casualty companies issue also policies on glass to the amount of $18,000,000, for premiums of nearly $400,000. This business is not conducted in any other country upon so large a scale, but is attracting more attention than heretofore in Europe, and especially in Great Britain.

There are at least four companies in the United Kingdom and five in America which make the insurance against damage by the explosion of steam boilers a special feature of their work, but by far the greater part of the business is transacted by one company in each country. The service rendered is one of special skill and vigilance, extending far beyond the contract for indemnity. The company, in fact, employs inspectors of the highest scientific qualifications, who assume constant supervision of the machinery, and require its structure and conduct to be freed from elements of danger. It is prevention rather than compensation that is sought, and the outlay made by the companies is mainly for inspection and control, not for losses. It is usual to promise in a policy upon a steam boiler some compensation also for any personal injury which may result from an explosion.

Two small companies in England have insurance against burglary for their principal purpose, while at least six of the British accident companies and three in America issue policies of this kind, but most of the business is in the hands of one company. It is an experiment of the last few years, and the risks taken are for moderate sums, $50,000 as a maximum, at premiums determined in each case by an estimate of the danger founded on a study of all the circumstances. There is no information published concerning this branch of insurance in other countries, but the aggregate premiums paid in the United States in 1899 upon $40,000,000 of property were almost exactly $800,000, and the losses were $100,000. It is believed by many that there is an important future for burglary insurance, in connexion with improved methods of protection, by safes, automatic alarms, and constant inspec-

tion, for dwelling-houses, shops, and offices, which are often unoccupied.

Insurance against damage to growing crops by hail is practised in several parts of Europe and America, commonly by small local associations on the mutual plan, or as an incident to the business of fire insurance. No statistics can be obtained ot these operations. The same is true of the insurance against the ravages of tornadoes, and against sickness and accident in domestic animals.

A wholly distinct business, commonly classed as a branch of insurance, has recently grown to great importance, that of guaranteeing the fulfilment of contracts and of indemnifying employers against defalcations in their service. The bond of a corporation of large capital is widely taking the place which personal surety has filled in connexion with undertakings on contract, and with offices and occupations of trust, both in public and in private life. Fidelity insurance is carried on by a few of the general casualty companies, but as the practice of it extends it becomes more and more the work of special institutions organized for this purpose alone. About fifteen of these in the United States are corporations of excellent standing, with aggregate paid-up capital of more than $15,000,000 and surplus funds of nearly $10,000,000 more, and collecting in premiums about $4,000,000 annually upon bonds and guaranties amounting to more than $1,250,000,000. The business has been almost wholly created within the last fifteen years. It has had similar if not equal development in Great Britain and in several other countries, but it is only in the United States that the statistics of it are officially collected.

The insurance of titles to real property has also become widely extended within a few years, and is conducted in the United States almost wholly by fourteen corporations, with an aggregate capital of about $5,300,000. Their business, however, has indemnity for losses as but an incidental purpose. The principal aim is to furnish a final and responsible assurance that the title is flawless. Several of these companies possess elaborate and expensive collections of records, covering the sources of title for cities or large districts; all of them employ expert ability of a high order; and when they approve a title as perfect, the purchaser or lender of money may receive, with the approval, a guaranty against loss in accepting it, which private examiners or counsel cannot give. Titles are insured also in other countries, but the business has nowhere else attained such importance, nor do the institutions transacting it make full and separate statements of its accounts.

Some conception of the volume of business now transacted in the several branches of casualty insurance may be obtained from the following summary of the latest published returns in the principal countries. It must, however, be observed that the aggregates given are those of the most recent reports of established corporations, and are not of the same date, those in the United States covering the business of 1899, while those in other countries are nearly all of 1898; nor are they complete, since many companies have published no statements, while the business of local mutual and assessment associations is not included. Further, no account is made of the premiums and losses of title insurance and mortgage guarantee companies. The summary is in every case reduced to pounds sterling:—

Premiums received and Losses paid Annually by Casualty and Fidelity Companies.

	No. of Cos.	Premium Receipts.	Losses Paid.
United States and Canada .	49	£4,476,096	£1,791,913
Great Britain	89	3,129,006	1,736,070
Germany	36	1,811,929	926,195
France	12	1,158,027	688,611
Switzerland	5	1,059,110	596,716
Austria	16	557,481	573,142
Russia	7	206,941	131,340
Belgium and Holland . .	8	187,526	75,831
Denmark, Sweden, & Norway	7	106,214	71,134
Italy	2	56,640	35,994

III. Fire Insurance.

The growth of the business of fire insurance since 1880 or thereabouts has been commensurate with the increase of wealth and of commercial activity in the foremost nations, while the practice of it has also become general in countries in which it was till of late little known. The statistics of the subject have in recent years become far more full and more accessible than formerly; partly because many Governments require detailed reports of resources, receipts, and expenditures from all companies permitted to establish agencies within their jurisdiction, and periodically publish summaries of the returns; but also largely because the companies seek the widest publicity as their best means of advertising. It is to be regretted, however, that there is as yet no uniformity of method in these returns, such as would make it possible to combine or to compare the results with entire confidence; while some of the most important elements of the subject are not sufficiently illustrated for the student in the published statistics. Those of the companies of Europe, including Great Britain, are defective in that they commonly give only aggregates of each branch of receipts, expenditures, and funds, without distinguishing the business done in different countries. Many companies of the United Kingdom transact business throughout a great part of the world, and there is no means of determining how much of their receipts or their losses must be referred to Great Britain. Further, they fail to give classified amounts at risk, so that it is impossible to estimate with any confidence the total sum for which any kind of property, such as dwellings, factories, household goods, stocks of merchandise, or wares in transit, is insured. The returns of the London Fire Brigade, however, which is in part maintained by regular contributions from the fire underwriters at the rate of £35 for each £1,000,000 of risks assumed by them within the metropolitan district, continue to exhibit a regular growth. The aggregate amount insured in the metropolis was reported as follows:—

In 1882	£696,715,141
1886	741,109,316
1890	806,131,885
1894	845,998,895
1898	909,962,574

It appears probable that the rate of increase here shown is not greater than the actual growth of insurable property during the same period, so that it may be reasonably supposed that the custom of protecting all exposed property by insurance was already general in London many years ago. But the transactions of the British fire offices have grown much more rapidly, and indicate that, outside of the metropolitan district, the practice of insurance has extended greatly. Thus for 1898 the net premium receipts of fifty-eight such companies were reported as £19,346,666, and the losses paid by them in the year as £11,546,080. The tendency to concentrate the business in the control of large capital and experience is shown by the fact that more than £18,500,000 of the premiums were received, and more than £11,000,000 of the losses were paid, by thirty-one companies. There were at the same time thirty-eight corporations of foreign countries with agencies for fire insurance in the United Kingdom, but many of these do but a nominal amount of business, and twenty-three of them are exclusively or chiefly engaged in re-insurance. This tendency has been a marked feature in the recent history of fire insurance everywhere. The companies which are now in the field are the survivors of tenfold as many projected enterprises which have failed. The records of about two thousand organizations for the purpose, in America alone, which have undertaken the work and disappeared within fifty years, show the dangers to which inadequate skill and capital are exposed. But a small proportion of these failures were the direct result of sweeping disasters, though about seventy of them followed the memorable fires in Chicago and Boston in 1871 and 1872. Many more, nearly one-half of the whole, have followed a short career, in which the helplessness of inexperience to compete with long training and complete organization was demonstrated. Many hundreds of these projects were mere speculations or even frauds from the beginning; and the better education of the community at large in the principles and methods of

insurance has been the chief agent in checking such enterprises, aided by the stringent legislation of several countries and of the states in America, and by the criticism of the press.

The difficulty of establishing a new joint-stock fire insurance company is far greater in the present highly perfected state of the business than formerly, and constantly increases. The reports of the insurance departments in the United States show that less than one-eighth of the premiums are now collected by companies founded since 1880; and, except in districts remote from the principal financial centres, or mutual associations for special classes of hazards, new ones are not often formed. In Great Britain a considerable number of new corporations are registered every year, with fire insurance among their professed objects (at least twelve in 1899), but almost always in connexion with some forms of casualty insurance, which appear to be practically the purpose in view. The reports of the fire business in the United Kingdom for recent years, as collected in *Bourne's Manual*, show that less than one-fourteenth of it is done by companies organized since 1870. Though new companies have been registered, usually several every year, the number actually transacting successful business has not increased since 1880. Of the sixty British companies now recognized, the twelve smallest together collect but 1 per cent. of the premiums received by one of the largest, and the tendency to concentrate the business seems progressive. These facts are explained by the necessity of a vast basis of average and of a large capital for security, and still more by the increasing demand for a thoroughly trained and organized body of agents, able to protect their companies from fraud and imposition, and at the same time to compete for public patronage. The competition among the companies is extremely sharp, and tends to break down such of their number as are deficient in any of these qualifications.

Mutual system.

The *Mutual* principle has a strong attraction for many insurers and projectors. The conditions under which it can succeed, in the practical conduct of the business, have been put to severe tests in recent years. When a large number of pieces of property, so distributed that a single fire cannot destroy a considerable proportion of the whole, are yet owned and controlled by persons who can fully trust one another, both for financial responsibility and for good faith, there may be no need of a large capital in hand, nor of much of the costly machinery required for general competition. A contract for the assessment on all the property of losses as they occur, at rates fixed by the estimated exposure, may form a safe basis for an association. The fixed payments may be limited to necessary expenses, with a moderate reserve for emergencies, all excess of collections to be returned to the insured. This simple conception of an insurance association, with such modifications as experience indicates, has been accepted for a time as ideal in almost every civilized community, and attempts are continually made to realize it, but in the vast majority of instances with complete failure as the result. Like every other product of human skill, insurance is, for the most part, best supplied to the market by those who make it their calling to produce it for gain. But while the mutual plan has proved poorly adapted to the general service of the commercial world, so that scores of companies founded upon it disappear every year, and the number of such companies is far less than it was many years ago, yet in some communities, and especially among the owners of certain classes of property, it has achieved great and apparently permanent success. This is particularly true of manufacturing districts, in which numbers of mills and factories are exposed to peculiar danger of fire by the nature of their own operations. The best safeguard they can have is by employing great skill in the construction, arrangement, and conduct of their works, placing them for this purpose under expert supervision, trained and organized to apply every device for the diminution of the risk. A group of such properties, associated for the prevention of loss, is naturally stimulated to highest efficiency when the whole group undertakes to bear all losses which are not prevented, and thus every member has a strong interest in making the protection complete. It is in associations of this character that the mutual plan of fire insurance has rendered its greatest services, and regulations for construction and management devised by such companies have in several instances become recognized standards for the classification and valuation of similar risks everywhere. The mutual plan has been widely adopted also in local associations for the insurance of dwellings and farm improvements, where the individual risks are small, and where technical classification and special safeguards against fraud are not considered necessary, often with the result of affording satisfactory protection at low rates. But the ratio of this part of the business to that conducted by joint-stock companies diminishes from year to year, even in the agricultural and rural districts of the United States. According to the reports of the insurance departments of the States, as summarized in the Spectator Company's Year-Book, more than half of the cash premiums of mutual insurance companies are collected in the two manufacturing states of Massachusetts and Rhode Island.

The criticism of the mutual plan in the article on Fire Insurance by Mr M'Candlish in *Ency. Brit.*, vol. xiii. p. 163, has been continuously justified by experience in Great Britain, where this system has failed to win a high degree of public confidence. It is also confirmed by the almost exclusive employment of the joint-stock plan in France, Belgium, Holland, Russia, and Norway down to the present time. But it must be qualified by observing that, under the fostering influence of the national and municipal governments, the mutual plan has reached an important development in the Austrian Empire, Germany, Switzerland, and Sweden. In all these countries, indeed, corporate enterprise on a large scale, in every branch of business, is of comparatively recent growth, and mutual fire insurance was a familiar practice long before joint-stock companies entered upon this field of activity. The tendency in the large cities and commercial centres is to throw new insurances into the business corporations, while yet the time-honoured mutual associations retain their standard character and customary clientage. But in these countries the mutual plan has an established place in the confidence of the rural population, who are generally strongly prejudiced against moneyed corporations. This is especially true of the cantons in Switzerland and certain districts in the Austrian Empire, where fire insurance is administered by the local governments in connexion with a minute police supervision of the construction of buildings and of other conditions affecting the risk. From the published returns of the companies and the authorities, as collected for the *Post Magazine Almanack* (1900), it would appear that of all the fire insurance premiums paid in Switzerland, nearly 54 per cent. is collected by the mutual associations and the cantonal authorities; while in Italy 37 per cent., in Germany 27 per cent., in Sweden 27 per cent., and in the Austro-Hungarian Empire 20 per cent. go to mutual companies.

Lloyds.

The earliest plan of insurance which was successful as a business was that practised at Lloyd's Coffee-house in London (fully described in *Ency. Brit.*, vol. xiv. p. 741), and there applied almost exclusively to marine risks. Although the association known as Lloyds has been for generations a strong financial institution, with every modern safeguard, and since 1871 has been a chartered corporation with large funds, yet its name has become accepted as the symbol of the primitive practice of combined underwriting by individuals, each upon his own credit, for a share of the risk, and without common liability. A few associations on this general principle were known to exist in America, and to issue fire policies on a small scale, before 1892, but chiefly for mutual insurance. In that year, in a general revision of the insurance laws of New York, such associations already in existence were expressly exempted from all its provisions. Speculators at once discerned an opportunity. If a company by omitting to take corporate form could carry on the business free from all restrictions and burden of state supervision, it would compete at great

advantage with the insurance corporations. While the new law was in prospect there was time to take action; and upon its passage there suddenly appeared a multitude of "organizations" claiming the exemption as Lloyds, or associations of individual underwriters, and offering fire policies at rates materially lower than those of the joint-stock companies. Each of these was represented and managed by an attorney for the subscribers, supposed to have power to bind them severally to the amount of their subscriptions. The standard policy prescribed by law in New York was issued, with a clause making the liability several only, and fixing the amount. The Lloyds entered the market with the zeal and prestige of a new idea and a great name, and they grew rapidly in number and in business, but made no reports. Extending their agencies into other states, they occasioned much litigation concerning their legal existence and rights, and some rash and inharmonious legislation. But several attempts to establish similar Lloyds in other places failed. Experience soon showed that it was impossible to enforce claims in the courts, when the liability was distributed among many, without excessive expense and delay, even when all the subscribers were solvent, while a few good names, however useful in canvassing, were no guarantee of the responsibility of unknown associates. In 1896 the executive and legal authorities of New York assumed a hostile attitude towards speculative schemes of this class, and indictments were found against a number of promoters for falsely antedating constituent agreements. The bubble burst suddenly, and within three years more than one hundred of the Lloyds disappeared. A few reinsured their risks or were merged in permanent companies, but the mass of them proved to have no substance. Four or five only of the best continue to issue fire policies within a narrow and special circle, but as a group they no longer compete for general business.

The *Tariff* system, described in the earlier volumes of the *Encyclopædia Britannica* (9th ed.), has steadily developed in minuteness of classification and in adaptation to wider experience, as well as to the changes in the character of many classes of risks by improvements in building and by the introduction of new kinds of goods and machinery. But the principles there explained are still recognized. The estimates of risk and the determination of premiums are largely governed by individual opinion and by competition, no amount of experience furnishing a statistical basis on which trustworthy predictions of average loss can be made. The irregularities and fluctuations in the extent of destruction by fire in different districts and periods of time continue to be great and incalculable, and risks can only be valued, within limits which render the business safe, by making use of the largest available basis of average drawn from the experience of many companies and many communities. Hence it is only by constant co-operation among insuring institutions in the exchange and combination of their observations that justice can be done to them and to the public. The proper extent of this co-operation is easily attained where the business is free from all restrictions except those of the common law, as in Great Britain, and the competition of capital for profits is keen enough to keep the rates within reasonable limits. But in countries in which the Government regulates the business in a more paternal spirit, and meddles with all its details for the avowed purpose of securing the safest and best public service, many difficulties arise. This is increasingly the case in several of the nations of Europe, notably in Austria, Switzerland, and Germany. But it is in the several states of the United States that the Government supervision of insurance has most interfered with and modified the natural development of the business. In recent years, beginning with 1885, sixteen of these states have enacted legislation, dictated by the growing jealousy of corporate powers and privileges, forbidding fire insurance companies or their agents to combine in any form for the determination of rates. Companies have often been indicted, fined, and deprived of authority to issue policies because of membership in associations for the purely scientific purpose of ascertaining their average experience. The courts have frequently narrowed in their interpretations the sweeping intent of such laws, but have generally sustained them as within the power of the legislature, and at the present time there is an overwhelming public sentiment in large sections of the country arrayed against every semblance of union or consultation among the companies upon the basis of their business. In several instances all the important insurance companies have withdrawn their agencies at once from particular states, and the business community has been sorely distressed for want of their protection. But the popular prejudice has not yielded to its demand, and the companies have never been able to maintain their own position with unanimity, the temptation to secure a vast business upon any terms being always too strong for some of them to resist. This form of legislation has beyond dispute increased the cost of insurance to the people, while it has embarrassed and disturbed the regular work of the companies. But it is a favourite subject among politicians of appeal to popular prejudice, and is likely to continue so until its uselessness and injurious effects become understood by the mass of insurers.

Tariff difficulties.

Another pernicious tendency of popular legislation is found in the *Valued Policy laws*, the first of which was adopted by Wisconsin in 1874, providing that when any insured building is wholly destroyed by fire the amount of the policy shall be conclusively taken as the amount of the loss. This principle, with various modifications and extensions, has now become law in twenty states of the Union, though in many of them its enactment has been vigorously resisted by the executive Government; several governors have vetoed such Bills, while most of the supervising officers have had the intelligence to disapprove them. The provision is regarded by all insurance authorities as highly dangerous, inviting over-insurance and incendiarism; and there is no doubt that it has this tendency in many instances. But the statistics available, while showing that in general the rate of loss has increased where such laws are in force, do not demonstrate any such wide and ruinous stimulation of fraudulent practices as has been apprehended by thoughtful critics. The actual result is commonly to throw upon the insurer the responsibility for providing in advance against over-insurance by minute surveys and, in special cases, for continual watchfulness against depreciation. Like all other interference of Government with private contract, however, it has a marked effect in increasing the difficulty and expense of business transactions.

Need of co-insurance.

The direction in which fire insurance as a social institution calls most pressingly for improvement is the extension of the principle of co-insurance. The importance of this can only be understood by remembering that the aggregate losses of the community by fire are chiefly made up of innumerable small fires, which destroy but a portion of the particular risk exposed, and not of sweeping conflagrations. Thus the fire patrol of New York, which surveys with extreme care every loss incurred in that city, reports the following summary of all losses during 1895–99, with the amount of insurance in force upon

the buildings in which the fires occurred and upon their contents:—

Buildings.

Year.	Insurance.	Loss.	Ratio Loss to Insurance.
1895	$19,954,269	$1,063,328	·0533
1896	24,753,499	1,015,187	·0410
1897	25,598,474	801,694	·0315
1898	39,326,676	1,382,553	·0351
1899	43,021,638	2,282,538	·0530

Contents.

Year.	Insurance.	Loss.	Ratio Loss to Insurance.
1895	$10,782,646	$2,371,570	·2199
1896	14,864,703	2,736,358	·1840
1897	12,133,154	2,208,997	·1820
1898	13,724,161	2,765,087	·2014
1899	32,013,617	4,899,229	·1530

The report for 1899 covers 6449 fires, of which twenty-two resulted each in a loss to the insurers of $50,000 or more, the average being $180,000; while for the remaining 6427 fires the companies paid an average loss of $495. There are few districts in which records so complete are kept, but the experience of every company confirms the general truth, that the number of fires in which a building is totally destroyed, or in which the loss amounts to the greater part of the property exposed under the same risk, is comparatively very small. It may be asserted with confidence that, in the grand aggregate of the business, much more than three-fourths of the loss occurs in fires in which less than one-tenth of the insurable value at risk is destroyed. The practical result is obvious. If fires destroy a million of dollars' worth in property insured for its full value, and a million's worth more in property insured for one-tenth of its value, the insurers will pay $1,000,000 upon the first group and more than $750,000 upon the second. But if all the insurance is taken at the same rate the insurers will have received premiums ten times as great on the former group as upon the latter. This rough illustration, which might be indefinitely extended, shows that in an equitable adjustment of rates the amount insured as compared with the value exposed is a prime element, and that premiums might justly form a scale, highest on the smallest fractions of value, and diminishing rapidly as the percentage of insurance increases. Such a scale is, however, impracticable for many reasons, apart from the endless complications which, even if it could be constructed, it would introduce into the classification of risks. Any scientific plan of insurance, therefore, must provide another method for maintaining the proportion between amounts of premiums paid and the share in its benefits obtained for them. This is the purpose of what are generally called *average* or *co-insurance clauses*. The principle is, that when a proper rate for a class of risks is found, then the insured may protect at that rate any percentage of such a risk, and in case of fire shall be indemnified for the same percentage of his loss. When once clearly grasped, this principle largely simplifies and rectifies the business. It is in universal use in marine insurance under the name of "average," and is there recognized as indispensable. It is embodied in all fire policies in France, Germany, and several other countries of Europe, and in 1826 was made compulsory in Great Britain by law in all "floating policies," those, that is, which cover stocks of goods distributed in several places and in fluctuating amounts. But it has not yet become general in Great Britain or America, although every writer of authority on the subject, and every practical underwriter of large experience, approves it. Systematic attempts have been made since about 1892 to extend its application in the United States with much success, but they have been met by strong opposition, which shows a widespread misunderstanding of its true bearing.

The co-insurance clause, indeed, which has been generally approved by the American associations of underwriters, and applied in the great commercial cities, is less sweeping than the parallel agreements used in France and Germany. The latter regard the insured owner as self-insurer for the entire value at risk not covered by the policy, and grant indemnity only for that fraction of the loss which the amount insured bears to the whole amount exposed. The American clause is less logical, commonly providing that: "If at the time of fire the whole amount of insurance on the property covered by this policy shall be less than 80 per cent. of the actual cash value thereof, this company shall . . . be liable only for such portion of such loss or damage as the amount insured by this policy shall bear to the said 80 per cent. of the actual cash value of such property." But this limitation of the basis of co-insurance average to 80 per cent. of the total value is in perfect harmony with the conservative policy which seeks in all cases to prevent over-insurance. The most serious danger to which the entire system is open is that a fire may promise profit to the insured. To avoid this, it is a small enough margin to exclude from protection by the policy one-fifth of the estimated value, and to require the owner to assume that proportion of the risk. It is therefore reasonable not to require in any case a larger share than four-fifths to be covered, and not to press the co-insurance principle so far as to offer a differential advantage to those who insure above this limit. Thus, for practical purposes, and in the general mass of business, the 80 per cent. clause may be accepted as approximately the best application of the principle. It makes possible substantial equity in distributing the cost, while it does not interfere with proper safeguards against over-insurance. The cordial support of the mercantile community in the great cities, and of the most intelligent state officers, has been given to it.

A popular outcry has, however, arisen against all forms of co-insurance, on the superficial and mistaken assumption that in every case the principal sum named in the policy measures the insurance paid for by the premium; and that any limitation upon it must be a wrong to the insured, for the emolument of the insurance corporation. No less than ten states have passed laws prohibiting the clause within their jurisdiction, though Maine in 1895, after a trial of two years, repealed the prohibition. The law of Tennessee, a typical form, is as follows: "Insurance companies shall pay their policy-holders the full amount of loss sustained upon property insured by them, provided said amount of loss does not exceed the amount of insurance expressed in the policy, and all stipulations in such policies to the contrary are and shall be null and void" (except in case of insurance upon cotton in bales). In several states the use of the co-insurance clause is made a penal offence. It is an interesting fact, however, that while this principle, whenever it has been generally applied, has led not only to a fairer equalization of premium rates, but, on the whole, to a marked reduction of them, the laws in question have deprived the people adopting them of the resulting benefit. In the year 1899 the average premium rate upon all fire risks written in the states in which co-insurance was wholly or partly prohibited was something more than $1·20 per $1000, while in the rest of the country, where the clause was permitted and to a large extent used, the rate was but 96 cents per $1000. The marked difference, which tends to increase, is a perpetual object-lesson which must in the end appeal strongly to the popular intelligence.

The varying attitude of several civilized Governments towards the institution of insurance has found significant

expression in their tax laws. In Great Britain a stamp duty of 6d. was imposed in 1694 upon "every piece of vellum or parchment or sheet of paper upon which any policy of insurance should be engrossed or written," and was doubled in 1698. It was further increased (reaching 3s. 10d. per policy in 1713) and varied by many subsequent Acts, under some of which the percentage duty on fire insurance was also made payable by stamps upon policies. But in 1865 the stamp tax was finally reduced to the nominal sum of 1d. upon each policy. A far heavier burden, however, was imposed upon insurers by the measure of Lord North in 1782, charging all fire insurances in force with an annual duty of 1s. 6d. for every £100 insured. In 1815 the general rate was made 3s. per £100, but was collected once for all upon the policy when issued; and it so remained until reductions began in 1864. The duty was wholly abolished in 1869. The revenue from this source reached its highest point in 1863, when it was £1,714,622, presumably representing insurances effected in that year to the amount of £1,143,081,333. There are no data for determining the amount of premium receipts or of losses realized on the same volume of insurance; but the tax was recognized by economists as well as by all parties to the policy contracts as an excessive burden. In many instances it more than doubled the cost of insurance. Its effect in discouraging the prudent custom of insuring against fire was very serious, and after its abolition this custom extended so rapidly that it soon became, and continues, practically universal in Great Britain. Upon the continent of Europe fire insurance is generally taxed quite heavily; most so in France, where the direct duties on the premiums, together with the registry and stamp taxes paid by the companies, have been estimated to add one-fourth, or perhaps one-third, to the cost of insurance. In the United States the companies are taxed, each by the state in which it is domiciled, upon their real estate, and often upon their capital, surplus, or profits, and are required in other states to pay fees to the insurance departments, and commonly an excise of from one to two and a half per cent. of their premiums. An elaborate table is prepared each year by a committee of the National Board of Fire Underwriters, showing the aggregate amount of taxes paid by the companies operating in New York in comparison with their receipts and profits. The statement received and published by the Board in 1900 contained the following:—

Taxation of insurance.

	For the Year 1899.	For Twelve Years 1888–99.
Premiums (fire and marine)	$134,450,639	$1,425,929,631
Losses paid (fire and marine)	91,031,677	856,978,494
Expenses	52,849,129	517,667,238
Increase of liability (unearned premiums, &c.)	8,998,526	59,104,388
Net loss in the last year	18,428,693	...
Net profit in twelve years	...	7,820,489
Amount of taxes paid	4,495,332	35,984,081
Taxes were of premiums	3·34 %	2·52 %
Taxes were of premiums, less losses	10·35 %	6·32 %

In qualification of this statement, it may be said that the reported expenses appear to include taxes, and that the additions charged to liability are to some extent theoretical and flexible. It also appears from the state reports that upon the entire capital and net surplus of $191,000,000 employed in the business in the United States by 316 joint-stock companies, dividends to the amount of $8,000,000, or 4·2 per cent., were paid in 1899 to shareholders. Nevertheless it is true that competition among the companies, together with unfriendly legislation, has reduced the profit upon their aggregate capital near the vanishing point, and that the taxes, the average rate of which increased 50 per cent. within the period 1891–99, are heavier in many states than can be justified by public policy or by the analogy of other corporate interests. The true principle, doubtless, is that while the capital employed in insurance for gain ought to contribute to the state the same share of its profits as other capital, yet the premiums, agencies, policies, and entire machinery representing only losses and providing for their distribution, should be exempted, as far as the necessities of the public treasury permit.

One aspect of the taxation of fire insurance is of especial interest, namely, the very general disposition of legislatures and municipal authorities to impose upon the underwriters the cost of fire departments. The systematic prevention and extinguishment of fires are everywhere assumed to be proper work for the community at large, and are commonly assigned to a special branch of the local government. But the first license granted by the Crown to issue insurance policies in London in 1687 was conditioned upon regular contributions by the authorities to support the king's gunners as a fire brigade, and in the public mind the privilege of insuring the prudent has ever since been vaguely associated with the duty of guarding the property of the whole community. The voluntary support of fire patrols by the companies in London, New York, and other cities has done much to promote this view; and a substantial part of the taxes paid upon fire policies in the United States is levied for the support of fire departments, the pay and pensions of firemen, and similar purposes. The tendency to increase such taxes, under the pretext that the protection afforded is for the special benefit of the companies, is strong in some of the states; though it would be equally rational to compel life insurance companies to maintain general hospitals for the sick.

The most complete statistics of the fire insurance business collected in any country are those presented in the *United States* to the National Board of Fire Underwriters at each annual meeting. The following table is a summary of part of the information submitted by the committee on statistics, 10th May 1900, giving the amount of fire risks insured in the United States, premiums received for them, and losses paid upon them, by all joint-stock fire insurance companies for the years 1897, 1898, and 1899:—

Statistics.

Fire Insurance in the United States. Joint-Stock Companies.

			Fire Risks Assumed.	Fire Premiums Received.	Fire Losses Paid.	Premiums per $100 of Risk.	Loss per $100 of Risk.	Loss per $100 of Premiums.
			$	$	$	$	$	$
1897	American Cos.	233	10,829,475,352	91,527,779	44,210,383	·8452	·4082	·4830
	Foreign Cos.	29	5,463,433,991	41,072,624	20,592,681	·7518	·3769	·5014
	All Cos. .	262	16,292,909,343	132,600,403	64,803,064	·8139	·3977	·4887
1898	American Cos.	226	11,397,206,093	90,071,290	50,655,461	·7903	·4445	·5624
	Foreign Cos.	32	5,924,875,178	40,338,900	24,025,856	·6808	·4055	·5956
	All Cos. .	258	17,322,081,271	130,410,190	74,681,317	·7528	·4311	·5726
1899	American Cos.	218	12,251,299,499	93,577,169	59,119,018	·7638	·4826	·6318
	Foreign Cos.	35	6,087,570,275	42,958,472	29,865,014	·7057	·4906	·6975
	All Cos. .	253	18,338,869,774	136,535,641	88,984,032	·7445	·4852	6517

These returns do not include mutual companies. The compilers of the *Insurance Year-Book*, however, have obtained from the several state departments of insurance the reports of all companies made to them of the business done within each state; and from these it appears that in 1899, 160 mutual companies assumed fire risks to the amount of $1,119,772,848. Many small local associations have made no returns, but their operations are too limited materially to affect the aggregate. It is noteworthy that while mutual companies transact less than 6 per cent. of the business of the whole country, yet in the state of Rhode Island, a densely peopled manufacturing community, they have more than 78 per cent., and in Massachusetts nearly 24 per cent.; and that, while less than one-ninth of the insured property of the United States is situated in these two states, they contain nearly two-thirds of that which is insured by mutual associations.

The fire insurance business of foreign companies in the United States was comparatively small until 1870. Four strong British

corporations were then in the field, and their transactions amounted to less than 9 per cent. of the entire joint-stock business. But their success attracted others in rapid succession, especially from Great Britain and from Germany, and in 1880, 19 foreign companies assumed 23·7 per cent. of all the risks reported to the National Board; in 1889, 23 such companies took 30·3 per cent.; and in 1899, 35 such companies took 33·2 per cent. The distribution of the business among them is not given by the Board tables, but can be gathered from the reports of the American branches to the insurance departments of the states, which are summarized in the Spectator Company's Year-Books. It appears from these that of 39 branches of foreign companies in the United States in 1899—

	Collected in Premiums.		Collected in Premiums.
24 British .	$35,266,610	1 Swiss .	$786,158
10 German .	5,540,504	1 Swedish .	435,125
2 Canadian .	2,754,292	1 Dutch .	406,098

In the *United Kingdom* the statistics of fire insurance are less accessible and less complete, no official returns or records being made of the local distribution of the property insured, while the published accounts of the companies are not sufficiently uniform and detailed to make a trustworthy summary of the entire business possible. Much of it is done by foreign companies, of whose British business we have no separate statement. The following statement of the revenue accounts of 58 British companies insuring against fire shows the aggregate premium receipts and payments for losses during 1898; and of 17 of them, which receive 70 per cent. of the premiums and pay about 70 per cent. of the losses, the total amount of insurance written in 1899 and of risks in force at the end of that year. Assuming that the remaining companies have a similar average rate of premium and of loss, the aggregate of the business of the British companies will be as found in this table:—

Fire Insurance in the United Kingdom. British Companies.

	Premiums received last Fiscal Year.	Losses paid last Fiscal Year.	Percentage Loss to Premium.	Estimated Risks written in 1899.	Estimated Risks in Force Dec. 31, 1899.
58 Companies.	£19,552,065	£11,971,868	61·23	£6,060,000,000	£7,100,000,000

These sums include business done by many of the companies in all parts of the world, and while they serve to indicate the volume of their transactions, they are no index to the value of property insured in Great Britain.

In the *Dominion of Canada* the insurance companies make detailed reports to the Government Bureau, and the statistics of the business are full and accurate. There were in 1900 seven Canadian companies, twenty-one British, and nine from the United States, taking fire risks in Canada; and the comparative share of each class, and its recent growth, are shown by the following statement of capital employed, and of risks assumed and in force, for the calendar years 1895 and 1899. The aggregates may be accepted as fairly representing the entire business in the Dominion:—

Fire Insurance Business in Canada.

	No. of Cos.	Year ending 31st December 1895.		
		Funds.	Risks written.	Risks in Force.
Canadian Cos.	5	$4,587,065[1]	$127,869,652	$143,522,252
British ,,	20	11,784,712[2]	445,816,220	565,683,862
U.S. ,,	7	1,212,822[3]	98,936,452	117,978,254
Total . .	32	$17,584,599	$672,622,324	$827,184,368

	No. of Cos.	Year ending 31st December 1899.		
		Funds.	Risks written.	Risks in Force.
Canadian Cos.	7	$5,003,818	$130,509,195	$169,792,859

Total . .	36	$22,200,938	$756,257,098	$936,869,668

[1] Including $1,889,920 capital paid in.
[2] Including $2,105,105 capital paid in.
[3] Funds in Canada only.

Upon the *continent of Europe* the fire insurance business is conducted, partly by local companies in each country, and partly by the great international offices of Great Britain and Germany. The local associations in Austria, Germany, and Switzerland are of three classes—public assurance organizations connected with local governments, private mutual companies, and joint-stock companies. It is impossible to obtain balance-sheets of all, nor is any information available concerning the local distribution of the risks, or the whole amount of property insured. The following table, exhibiting the capital employed by stock corporations in this business in each country, and the aggregate premium receipts and payments for losses in the last year of which a report is available, has been compiled almost wholly from the statements collected by the *Post Magazine Almanack* for 1900. In most cases the figures given are for the operations of 1898, but the fiscal years are not the same for all. The capital in each case is that actually paid in; the subscribed capital is usually much larger. The amounts are reduced to pounds sterling:—

While most of the fire insurance business in the *Australian colonies* is in the hands of British companies,

[4] Many of the mutual companies in Germany and Austria are divided into distinct departments, one for houses and one for personal property, with separate accounts, but being under the same management, the two are here regarded as one company.
[5] Seven companies not reported.
[6] Two companies not reported.
[7] Four important companies not reported.
[8] Statements incomplete.

local institutions for the purpose have had a considerable development on the same general lines as in Great Britain and with similar freedom from interference by the governments. But no accounts of the receipts and losses are available, most of the companies conducting a marine or life insurance business, or both, under the same general management. There are at least five flourishing companies in Melbourne, with paid-up capital of £272,500; five in Sydney, with paid-up capital of £190,000; five in New Zealand, with paid-up capital of £484,000; and two in Tasmania, with paid-up capital of £87,500.

Beyond the limits of the great commercial nations, no satisfactory information is accessible concerning the practice of fire insurance. Even in Spain and Portugal there is far less intelligent interest in the subject than in neighbouring countries, and the agencies of foreign companies transact much of the business in the large towns. Six Portuguese companies have maintained themselves for many years, a few of them for nearly a century, and have established agencies in the Spanish islands and in Madeira. For other nations than those represented in the table above, the only systematic effort to collect the facts is made by the compilers of the *Year-Book*, and the results are extremely meagre. The great British and German corporations are zealous in extending their transactions to the commercial ports everywhere, and local companies are often formed in the colonies. It is only in Australia and in Cape Colony that these have become financially important, though small native companies have been successful in establishing their credit in Japan, Brazil, the Argentine Republic, Chile, and Peru. A considerable business is done in insuring the property of foreign residents in the Levant, on the coasts of Asia, in South Africa, and the Pacific Islands, but mostly by European companies, and as an incident to the more general practice of marine insurance. There are several successful fire companies among the Dutch in Java, and, under British management, two at Georgetown in British Guiana, and one in the Transvaal. The small business in Mexico appears to be wholly in the hands of foreign companies.

IV. Life Insurance.

Before the middle of the 17th century no marked improvement had been made in the method of collecting and classifying social facts since Herodotus and Pausanias. General descriptions, mostly from personal observation, extended by hearsay, with vague inferences, were the sum of available information on the volume and movement of population, industry, and wealth. A few German and Italian writers had attempted large collections of comparative data in this field, but without trustworthy sources or useful method, so that their labours served only to indicate a want, not to supply it. In 1609, indeed, Sully, the great minister of Henry of Navarre, ordained a permanent national bureau to inquire into the economical and social conditions of the kingdom, but this magnificent scheme, in advance of his age, fell with the tragic death of his master. The fruitful use of statistics was impossible until the principles of the science of probabilities were grasped; and as these gradually became part of the common stock of ideas among advanced minds, statistical method was developed. The famous correspondence between Pascal and Fermat in 1654 shows two of the greatest minds of the age engaged in groping painfully after solutions of problems which are now considered elementary, the thought that probabilities can be definitely appraised and compared being grasped as a fresh discovery. Step by step a new science was created, that of the laws governing events whose causes cannot be traced. The leading conceptions of this science were firmly implanted first in the minds of a few mathematicians, were then applied to the study of social facts, especially those of human mortality, and in succeeding generations have become familiar to all educated men. The world has slowly but thoroughly learned that events which individually are impossible of prediction, whose determining forces defy analysis, and which to us are therefore casual, tend to occur with greater and greater uniformity the larger the number of instances collected; that averages are the clues to general truths, and that deviations from average diminish as instances multiply, while any persistent failure of such deviations to diminish is the clear indication that some disturbing force is exerting a uniform influence which requires investigation. Until these principles were clearly understood life insurance was impossible. They first began to find acceptance with the foremost thinkers of Europe during the second half of the 17th century. If their gradual development could be traced for the last three hundred years, from the first hints of mathematicians, philosophers, and statesmen, to their general recognition in modern research, it would form one of the most important chapters in the history of thought.
